INDUSTRY'S LIGHTEST METAL

The easiest of all metals to machine

Dowmetal is a revelation to machinist and finisher. Put it on a lathe. Watch it take a roughing cut of $\frac{1}{8}$ to $\frac{3}{16}$ inch at 200 to 600 feet per minute. Or give it a finish cut of $\frac{1}{64}$ to $\frac{1}{32}$ inch at 1000 to 1400 feet per minute. That's real speed in machining metals. Yet with Dowmetal, you find no tendency to drag or tear. You get a fine, smooth finish and clean, sharp threads.

On surface finishing operations, its fine properties are even more evident. Dowmetal parts and patterns can be finished in less than half the time of other metals. Scraping, filing and similar operations are twice as easy, twice as fast. Think of the saving this means in the production costs.

On screw machine products, machines have been run at their maximum speed without overheating the work. The ease and smoothness of drilling, tapping and reaming operations is amazing. You have no trouble in overheating tools or of metal building up ahead of tools on fast work.

Take useless dead weight out of your products

With all these advantages, you have the benefit of the lightness in weight to be carried to and from machines, as well as lightness of the finished product.

It will interest you to know also that this lightest of all structural metals can be drawn, rolled, forged, extruded, cast and welded by processes common in industry. Get the New Dowmetal Data Book. It gives both technical and practical working information.

EDITORIAL COMMENT

THE COATING OF METALS

FEW things in this world are used without some special preparation of the surface for the purpose in hand.

Paper is calendered to give it the proper finish. Houses are painted to protect them from the weather. Walls are papered. Flappers' faces are cosmetized. Glass is polished, cakes are iced, and so on for nearly everything one can think of.

Whether the coating or smoothing of the surface is for appearances' sake only, or to increase the life of the underlying material according to the slogan, "Save the surface, you save all," the proper preparation of the surface is an essential step in the manufacture of almost anything we want to sell. Metals are no exception.

Rust, tarnish, corrosion and abrasion are evil enemies that must be fought by the users of metals. All these attack the surface.

One way of defeating them is, of course, to find a material whose interior and surface both have the properties desired at those locations. But such a choice is usually a compromise, and even the corrosion resistant non-ferrous alloys and the stainless steels do not always have exactly the properties wanted both inside and out.

Usually a strong or a very readily formable cheap alloy for the interior, and a thin corrosion-resistant, wear-resistant or decorative film of another material on the surface, is the most economical combination.

The coating of metals is therefore a matter of importance to the producer and user of metallic parts, and one which the metallurgist must consider.

For utilitarian purposes, we have carburizing, nitriding, and the welded-on overlays, as well as chromium plating to resist wear, hot galvanizing, tinning, coating with terne, with lead, etc., sherardizing, calorizing, metal spraying, use of duplex metals of the Sheffield plate, Alclad and Niclad types, electroplating, anodic and allied treatments of aluminum, rubber coating by electroplating and otherwise, Parkerizing and oiling, and certain types of painting.

For combined corrosion resistance and for decorative effect, or for decorative effect alone, we have vitreous enameling, painting, varnishing, lacquering, Japanning, mere polishing of the surface, electroplating and polishing, coloring, dyeing of anodic films on aluminum and so on.

Some of these are meant to be as permanent as possible; others, like paint, are intended to be renewed at intervals.

Modern nitrocellulose lacquers and those of the Bakelite or other condensation resin type, with the different solvents, driers, resins and pigments in these and the older paints, varnishes and lacquers, are complicated subjects in themselves, and their permanence, gloss, hiding power and chemicals resistance are matters on which many technologists are putting long and careful study. Bronzing pigments and the increasingly important flake aluminum pigments, bring metallurgy into play in these coatings as well as in the materials to be coated.

Vitreous enameling has grown greatly in recent years, and only requires the development of an enamel with a little more flexibility to conquer even wider fields.

Electroplating took a sudden spurt when the chromium finish finally found favor, and the plating industry is slowly becoming a science instead of an empirical art. Problems of adhesion, pinholing and throwing power are grave, and the myriads of possible variations in plating solutions, current density, temperature, degree of agitation, in depositing this and that metal upon another make this, too, a very wide field.

The selection, cleaning and preparation of metal for taking any one of the various types of coatings must be done with a view to the coating to be used. Roughening the surface as by sand- or grit-blasting is essential for metal spraying and for some paints, and quite too little is known about sand-blasting.

Polishing of a metal itself, or of a plated coating, is an operation that usually involves an astonishing proportion of the total cost of a finished article. Too little is known about the polishing process or about why one polishing powder works well or poorly on a given metal.

Too often the metallurgical engineer views the question of metal coating as a problem for the chemical engineer. Instead, it is a joint problem, one that will benefit by coöperation between both chemical and metallurgical engineers.

In this issue, we discuss a few of the multitude of factors involved in the coating of metals, and we plan to give continual attention to this type of problems, believing that they are of greater importance in metallurgical engineering than most engineers recognize.—

H. W. GILLETT

EACH and every member of the Editorial Board of METALS & ALLOYS hereby expresses his warmest good wishes to you for a very Merry Christmas, and that the coming year will bring you all the successes and blessings and fulfillment of your strivings.

Engineering Demands for Metallurgical Research

The metallurgical research groups in universities and government institutions not directly connected with industry are guided by several influences in the selection of their research problems. Expediency—what topics can be handled with the funds, equipment and personnel available, interest—what the professor or supervisor and the student or worker may like to do, the needs of pure science as those in charge visualize them, and, finally, industrial need for new or more exact information, all play a part in the choice.

The problems selected for attack by the research laboratories of industry itself are chosen, and properly so, with a view to the dollars and cents value of the information to each particular firm. Many of the firms with long experience in research find it necessary, in order to build a sure foundation of fact, to delve deeply into the pure sciences that underly their particular industry, but delving in specific directions and for clearly understood purposes. To such an extent is this done that more work of real value in pure science along the lines of physics and engineering, at least, is coming from the industries than from the universities. Not only is this true as to the total amount of work, but, since the subjects are selected because of a real need and the work is carried through as far and at such a rate as appears to be a good investment, instead of being stopped when an interested professor retires or the funds allotted for university research are exhausted, the quality of the work is higher on the average.

Any firm, however, finally comes to the point where its own interest in going still more deeply into a given research field is somewhat remote, yet sufficient to justify its joining in to till it further with others with similar indirect interests in the field. Such general problems, as well as some of pressing commercial interest which lead to specifications and that sort of thing and so require joint action, are natural subjects for study by committees of national technical societies. The financing of joint problems of this sort presents difficulties and there are other difficulties due to the multiplicity of counselors.

When all feasible joint action is taken, another borderline is reached where the industries are, in general, no longer willing to give appreciable financial support, but are willing to suggest the research lines they would like to see others, especially the universities, follow.

While such suggestions may fail to include the more immediate and vital problems that are under study in the laboratories of the industries themselves or slated for such study, yet they are of interest as showing some of the subjects on which industry feels a need for more research information.

Such a list of engineering research subjects has been secured, in reply to a questionnaire, by the Committee on Engineering Research of the Society for the Promotion of Engineering Education, and is published in a Supplement to the Journal of that Society, issued February 1931, pages 107-131.

Some of the replies were written with an appreciation of the fact that the Engineering Experiment Station or other research group at most engineering schools is severely limited in funds, in time of the instructing staff available for the direction of research, in available workers of sufficient maturity, and especially in workers who can apply full time and energy rather than a patchy kind of attention between classes, hence, these replies mention only subjects that might receive useful attention despite these handicaps. Other replies obviously do not take these limitations into account and list problems that are plainly out of the scope of many institutions, such, for example, as one "Engineering Experiment Station" created in 1907, whose available funds for research for 1929-30, as listed in another part of the Journal cited, amounted to the gorgeous sum of $700.00.

Without discussing here how far such engineering research groups are likely to get, if and when they do attack the problems, the subjects suggested are worth glancing at. It is enlightening to see how many of the subjects mentioned deal with metallurgy. Indeed, comparing the ratio of purely metallurgical problems that have been or are being studied by university engineering research groups, as listed in the Journal, to that of the list of problems put forth by industry, it seems plain that metallurgy is getting less attention from such groups than industry advises giving to it.

The firms whose engineers responded to the questionnaire with fairly specifically worded subjects were American Brass Company, Atlantic Refining Company, Belden Manufacturing Company, Cochrane Corporation, Crucible Steel, Chrysler Corporation, De Laval Company, Detroit Edison Company, Du Pont Company, Hoover Company, International Harvester Company, New Jersey Zinc Company, Radio Patents Corporation, A. O. Smith Corporation, U. S. Radiator Corporation and Westinghouse Company. Some subjects previously suggested to the American Society of Mechanical Engineers by industry were also included. Only three of these firms would class directly as producers of metallurgical materials; all the rest fall into the user class.

Several firms mentioned the allied problems of wear and friction and lubrication of bearings, while abrasive wear, such as is met in dredge pumps and in handling powdered coal, interested others. Brake drum wear and friction of drums and linings, as well as the general problem of determination of coefficient of friction, abrasive wear and saving of energy lost through friction of soil and tool in farm tools, and the selection of abrasives for specific grinding problems were also mentioned as important.

Corrosion problems specifically mentioned were: caustic embrittlement, effect of deaerated water, the effect of impurities or additions of Al, As, Si, Zn, Sn, Mn, Ni, on the corrosion of copper, corrosion by high sulphur crude petroleum, by sulphur gases, etc.

The need was expressed for more information on the properties of metals at high temperatures, study of engineering design based on plastic flow, effect of varying temperatures and stresses as contrasted with the usual high temperature creep test, and thermal conductivities at high temperatures.

Mechanical hysteresis or internal friction in respect to resistance to repeated stress, mechanism of failure of metals, and studies of the effect of rate of loading in various mechanical tests were mentioned.

Machinability in all types of metal cutting, the characteristics of metal cutting in general, various problems in regard to deep drawing, stamping and forming, both from the point of view of the operations themselves and of the selection of materials most readily cut or formed, were important in the eyes of several.

Some general subjects for attack from the experimental and theoretical point of view were: elastic coefficients, electrical conductivity, more accurate equilibrium diagrams, study of volume changes during solidification, and the effect of gases and inclusions in steel.

A few more specific problems were: selection of suitable steel for dies for aluminum die castings, means for determining the true softness of copper magnet wire, maintenance of the film in electrolytic condensers, study of radiation from fins of copper, aluminum, steel, cast iron, etc., use of bronze in welding iron and steel, reflective properties of chromium plating, etc., and how best to fasten wire ropes.

It is evident that those factors which make for too short life in severe service under abrasive, corrosive and high temperature conditions, bulk large in the eyes of engineers.

Knowledge on friction and lubrication problems, too, is apparently not yet in a state that satisfies the engineer.

Most of the problems mentioned require the combined points of view of the engineer, the metallurgist, and the physicist, and many of them, the study of high temperature properties, for example, call for rather expensive equipment and uninterrupted effort, which only too rarely can be supplied by universities. It is a pity that our engineering schools do not attract more graduate students who might be competent, under suitable direction, to handle such projects, and that so few schools or engineering experiment stations make research a full-time task for certain professors and capable workers. Until this situation is remedied, about all that can be hoped for is a better realization of the possibilities of research in engineering metallurgy by the faculties of physics and chemistry, since those sciences attract many graduate students who would really be better prepared for later work than they are by working on the problems normally selected by their teachers, if they coöperated in research along the lines mentioned above as desired by industry and along similar lines on which any university could ascertain the desires of industry.—

H. W. Gillett

Good Will

The older we get, the more impressed we are by the fact that people in general, and technical men in particular, don't get paid solely for what they know or even for what they can and do accomplish technically, but also, and to no small degree, for the way they get along with other people.

A man who is himself pretty much of a light-weight scientifically, but who has some horse-sense and who has the faculty of making friends that will be glad to help him out when he needs help, is, as a rule, far more useful to an organization than the "prima donna" type of genius who can't and won't work with others.

There are a few university professors and even an occasional public official, who not only used to have high scientific standing in their younger days, but were also well liked, who are lately slipping badly in the esteem of their fellow scientists solely because they have acquired an ingrowing sense of their own importance, and have become overbearing in their discussion and criticism of the work of others. We recall one such discussion at a technical society meeting where a professor criticised a paper, the conclusions of which were admitted by the author to be open to discussion, but which were at least worthy of thought and further study. The professor could have couched his criticism in such a fashion as to make plain that he disagreed totally and that his scientific honesty forced him to present the other side of the picture in an impersonal fashion, but that he recognized that the author not only had a right to his own interpretation, but also was doing a service by presenting his results and opinion. Instead, he phrased his criticism in such a fashion that his hearers felt that his opinion of the author was that the author was a fool and hence that nothing in this paper could deserve credence. It was not a discussion; it was a diatribe.

The result was that every one in the audience rallied to the support of the author whether they agreed with his conclusions or not. In ten minutes, that professor earmarked himself as a sour and unfriendly spirit, losing his own prestige, and boosting that of the man he was attacking.

We recall another technical meeting at which there was presented a rather amateurish account of some sketchy undergraduate work at a small college, done under decided handicaps as to equipment and guidance. After some criticism, fairly well deserved and not of a vituperative nature, but which nevertheless would tend to dispirit the youngsters and their teacher, Dr. Whitney remarked that some of the observations of the authors opened up useful fields, and that the society should en-

(Continued on Page 336)

AGAIN unforeseen conditions have forced us to omit the metal cover on this issue. Through the courtesy of the American Brass Company we received a sufficient quantity of Everdur (0.1 inch thick). This material was shipped to the Cold Metal Process Company to cold roll down to 0.002 inch. The processing, to provide the material with properties suitable for our cover, requires cold rolling to 0.01 inch, then annealing in a bright annealing furnace and finally cold rolling to 0.002 inch. The Everdur will therefore be used on our January issue.

The Japanning of Steel

BY WILLIAM J. MISKELLA*

Fig. 1. Crystal Japan (Actual Size).

THAT japanning is an important type of metal finishing is confirmed by the fact that eleven standard forms of conveyor-type ovens have been developed within the last fifteen years for handling the large volume of parts which are finished by this most interesting process. Of course, this does not cover the entire field for there has been designed special equipment for automatic handling as well as a large variety of stationary type.

Who can say that the field covered by this durable and popular finish would not have been widened had it not been for the narrow-minded policy of those in the job-japanning business in the early days. Then the japanner thought he had something no one else knew much about—and he did, but that did not bring in volume business. In those days very few manufacturers had their own japanning departments and the secretive methods with which the job-japan shop was conducted, as well as the manner in which the formulae for making the various types of japan were guarded, surely retarded the industrial application of a finish which has many interesting properties.

Production demands of the automobile industry forced the issue and created the need for the continuous finishing of metal parts in order that costs might be reduced, quality might be improved and most important of all speed in finishing be introduced. To show just how successful this demand was in upsetting the order of things—it was the standard practice in job shops 15 or 20 years ago to take 24 hours to pass through the cycle of applying one coat of japan. To-day it is possible to duplicate the same process, and obtain better results, in one hour.

Just what is japanning? This is a pertinent question and one which is difficult to answer for the little literature which is to be found on the subject is so confusing and there are so many conflicting statements that is it really difficult to know what is authentic. There is no other finishing material just like japan in its make-up. Japanning could be defined as a process of applying a mineral coating to metal surfaces—a coating which deteriorates less with age than any other known material applied in liquid form. Japan looks like paint and is often

* Consulting Engineer on Finishes and Finishing Problems, Oak Park, Illinois.

Box-type oven for small jobs.

Fig. 3. Semi-automatic for handling small parts.

Fig. 2. Crinkle Japan (Actual Size).

erroneously called paint, yet it is as unlike paint as water is unlike oil.

Paint is a coating material made up of a pigment which gives it color, a drying oil which gives it life, a drier which hastens its hardening or drying stage and a reducer which conditions it so it may be readily applied. The duration of the existence of the paint film rests with the life of the drying oil—when that ends the paint disintegrates and chips or falls off—and all within a few short years.

Baking japan also contains all of these ingredients in one form or another with the one exception that the pigment used is peculiar to baking japan and differs materially from that used in paint. This pigment is obtainable in a variety of black shades, but always black for there are no colored japans in the true sense of the word—the colored finishes are enamels. The pigment is not affected by the heat used in the japanning ovens. Japan is a member of the asphalt family and is known as gilsonite.

There is another difference between paint and japan. In paint the drier used is a chemical which acts on the other ingredients to hasten oxidation of the film on the surface of the article being finished. In the japanning process no drier is used but the baking oven capable of supplying heat up to 400° F. performs the same function that the drier does in paint. Paint without drier and japan without being baked would otherwise take weeks and weeks to dry and even then there would neither be the same ultimate result or anything like the same quality of finish, and the finish would always be sticky to the touch.

The heat in the japanning oven causes the material to flow together in a smooth uniform coat as is seen on practically every automobile fender (black finished). Once the japanned parts have passed through this baking process they receive—when properly applied—the most durable and highly satisfactory metal coating in existence. Besides the automobile fenders, typewriters, sewing machines, stove parts, airplane engines, calendar pad holders, hardware items, various toys, etc., are all black japanned.

From the standpoint of cost it is the cheapest known metal finish there is and by far the most durable, not even excepting nickel plating, pyroxylin lacquer or spar

Electric Oven of the truck-type.

Fig. 4. Modern-type Spray Booth with distributing plates in the back for collecting the waste when spraying japan parts.

varnish. It cannot be applied to wood or any material which cannot stand being baked at a minimum of 325° F. This leads to the definite classification of baking japan. All materials which are applied and baked at temperatures below 325° F. are not japans.

Naturally one would infer that the process had its origin in Japan, but, evidently it did not for it is recorded that in the beginning of the third century the Japanese made an expedition to Korea which was then a Chinese possession and took back with them to Japan a lac tree which they naturalized and later commercialized. There is no connection whatsoever between the japan of to-day and this ancient lac tree—only the origin of the name. This statement does not apply to japans alone but includes driers, varnishes, enamels, lacquers and other similar finishing materials. The real oriental lacquers are produced from the sap of the lac tree and are marketed under different names, as Chinese, Japanese, Foochow, Cinnebar, etc. The lacquers of our industrial markets are known as pyroxylin or nitrocellulose lacquers. These are chemical compounds—an American invention—made from cotton and corn raw materials. (I might mention the lac tree of Japan is similar to our American sumac.)

Japan used to be called "japan varnish" but soon the term was shortened to japan. The term "japan varnish" is used in one of the oldest United States patents, taken out in 1856 and assigned to the Howe Manufacturing Company of Derby, Connecticut. This interesting patent covers the japanning of pins and reads just as if it were taken out yesterday, with the exception of the term 'japan varnish."

Burn-off Oven at Marmon Motor Car Company (Courtesy Young Brothers Company).

Dip Tank and Second Coat Dip with Japanning Oven at Marmon Motor Car Company (Courtesy Young Brothers Company).

The test for japanned articles may be made as severe as possible, providing, of course, the japan finish is properly applied on a perfectly clean surface using the proper materials and under the proper baking conditions. As an example of this let me give you the standard specifications of the Department of Electricity of the City of Chicago:

All surfaces of the tube should be protected against corrosion by one of the following or some other approved method:

The japan coating on either the inside or the outside surface of the finished conduit must not soften at ordinary temperature. It must have an even and smooth appearance and must be of uniform quality at all points the entire length of the tube. It must be of sufficient weight and toughness to resist smashing or flaking and must be of sufficient elasticity to prevent its cracking or flaking at any time up to one year from the month of manufacture when $^1/_2$-inch conduit is bent in a curve, the inner edge of which has a radius of three and one-half inches.

The japan coating must not be seriously affected by soaking at 70° F. for 24 hours in any of the following aqueous solutions:

1. Sulphuric acid of 1.3 specific gravity containing 40% by weight of anhydrous sulphuric acid.
2. Commercial strong hydrochloric acid containing 20% by weight of anhydrous hydrochloric acid.
3. Acetic acid containing 20% by weight of anhydrous acetic acid.
4. Saturated solution of carbonate of soda containing 20% by weight anhydrous carbonate of soda.

Japan drier (also called japan driers and sometimes just driers) is a colorless liquid which itself dries to a hard film having considerable coherence. Its principal use is as a vehicle for grinding coach painting colors. Colors which are bought by the user are, for example, red ground in oil, or red ground in japan, or even red ground in varnish. Colors which are ground in japan dry much quicker than colors which are ground in oil.

It should be understood that japan drier does not enter into the formulae of baking japan in any way whatsoever. Japan drier is used in air-dry paints to chemically hasten the drying, while heat, through the medium of a japanning oven, is used to hasten the drying of baking japan. (And let me add here that the addition of drier to any kind of paint is considered a detriment and shortens the life of the coating, but regardless of this fact there are places where it must be used.)

"Rubber" japan receives its name from its similarity in appearance to hard rubber. Dull black japan is a form of "rubber" japan that is devoid of gloss. The dullness is due to the amount of pigment ground into the vehicle or liquid by the manufacturer and secondarily

to the degree of heat applied in the baking process. Dull black japan is used on most telephone stands the world over. "Rubber" japan is used as a first coat because of its binding and covering quality. Literally it seems to flow into the pores when the metal to which it is applied expands within the oven during the baking process. A typical formula for "rubber" japan is:

Black japan	3/8 gallon
Turpentine	1/8 gallon
Kauri varnish	1/4 gallon
Carbon black	1 pound

There are a number of different shades and grades obtained by varying these proportions and by intermixing gloss black baking japan with rubber black baking japan. The latter is really gloss black baking japan with enough carbon black pigment added to deaden its gloss. Then sufficient turpentine is added to reduce the mass to working consistency. The Kauri varnish is included to assist in grinding the carbon black into the mixture. Incidentally the carbon pigment often settles upon standing which means that a "rubber" solution must be stirred, or agitated, before using.

Sometimes streaks and strips are noticed in "rubber" coated parts after they have been dipped. This defect is due either to poor mixing or grinding at the factory or to insufficient agitation prior to use. It is the pigment that furnishes the covering and opaque quality to "rubber" japan. It looks very much like Bower-Barff.

The real Bower-Barff finish which is said to be rust proof is used on much of the high-grade building hardware. It is named after the originator. The real process is performed as follows:

The iron or steel articles should be chemically clean and given a light sandblasting. They are then placed in a closed retort or furnace where they can be heated to cherry red—about 1250° F. When the articles have reached this temperature super-heated steam is injected into the retort, which develops a black magnetic oxide of iron upon the steel or iron. It takes several hours to produce a good coating. When cool the surface is wiped with a thin coat of linseed oil and then heated at 212° F. until the oil becomes dry. This changes the magnetic oxide to a slate gray or the regular Bower-Barff finish.

This process is a close imitation of dull black baking japan. It is so good that it is difficult for one not an expert to tell the difference.

Black baking japan (which is also called Brunswick japan) is the most popular and also the most used japan. It may be applied as a filler, over "rubber", or over itself, but it is more often applied alone. It has a glossy appearance, is hard and smooth when it comes out of the oven and keeps that appearance under the most adverse conditions. It is very elastic, is non-conductor of electricity, is acid-proof and water-proof. It is also alkali-proof to a certain extent. It is usually shipped in five-gallon cans or in fifty-gallon drums. It does not settle or separate and does not have to be stirred, except just after being reduced with benzine. Black enamel differs radically from black japan because it is really a varnish.

Intermittent Conveyor Showing Dip Tank and Drain Board used with Intermittent Japanning Oven at Marmon Motor Car Company (Courtesy Young Brothers Company).

Overhead Trolley System for Handling Fenders at Marmon Motor Car Company (Courtesy Young Brothers Company).

And now let us consider some of the crystal japans, which are popularly—though erroneously—known as crystallizing lacquers. These finishes are really very beautiful; and, as the name indicates, are finishes having an alligatoring or crystal effect, as shown in Fig. 1. They are used quite extensively on precision instruments, camera parts, radio parts and the like. Even larger articles are now being finished with these finishes such as scales of various kinds, store fixtures. Some metal-casket manufacturers are applying them to caskets in various colors—dull bronze, lavender and black and they are very beautiful indeed.

The material should always be bought fresh and from a reliable manufacturer. There is a certain manipulation of the oven which is necessary to produce these crystals which are a mixture of alternate dull and shiny spots between the wrinkles caused by the raw oil used in the material.

The oven must be brought up to a temperature of

Electric oven—The heat of the air-cooled engine cylinder does not burn off the japan coating on the airplane motor castings being japanned.

100° F. and kept at that point for about $^3/_4$ hour. During this time the air intake vents are closed and the work is kept in darkness. At the end of the stated time the crystals are formed, then the vents may be opened and the temperature raised to 350° F. for $^1/_2$ hour. (It could be baked at 250° F. for 2 hours.) This material is best handled in an open-flame type gas japanning oven since it is the sulphur in the gas and lack of oxygen in the oven which is necessary to aid in producing the crystals. The heavier the coating the larger the crystals will be and vice versa.

This crystallizing effect can also be produced in colors by using clear material, as above, without pigment, on whatever color of background one desires, care being taken not to bake at high enough a heat so as to harm the background material. Beautiful and artistic color effects may be gotten by intermixing colored crystallizing lacquers or in shading crystallizing colors by adding black crystallizing lacquer.

Another type of finish similar to crystal japan is called crinkle japan and is illustrated in Fig. 2 This finish is secured by placing the freshly coated parts into a very hot oven. The oven used should be of the indirect type, which means that pure air and not foul air is essential—thereby differing radically from crystal japan. However, a direct oven will produce the crinkle effect.

There are a number of processes of applying japan, including brushing, dipping, spraying and roller coating, but the two principal processes are spraying (Fig. 3) and dipping (Fig. 4).

In Fig. 5 is illustrated a continuous conveyor, which, as the name indicates, provides a continuous system of finishing. The parts to be finished are hung on the loading end of the conveyor and once in position are carried through the entire process, finally reaching the end of the system where they are unloaded and packed ready for shipment. The freed conveyor chain continues back to the starting point where it is available to take up another load of parts.

Fig. 5. Continuous conveyor oven for handling small parts.

Some continuous conveyor ovens, called the A-type because of their form, are shaped just like the letter "A." These ovens are the result of various experiences and designs and are now said to be the last word in japanning ovens from an efficiency standpoint. The curves shown in Fig. 6 explain this most fully. Please note that the 2 curves are also "A" type and that the hottest point or peak is reached at the top or apex of each unit.

As the temperature decreases, the location of the work on the conveyor approaches closer and closer to the end of the oven's units. The shape of these units holds the hot air within the oven so that it cannot escape without giving up its useful energy. Thus, all the heat that it is possible to reclaim out of a certain heat application is redeemed.

Two of these "A" units are placed in series and are connected by a common continuous conveyor moving at the rate of 16 inches per minute (in the installation covered by the curves). They have a capacity of approximately 140 tons of two-coat work per day. The installation is about 200 feet long, 8 feet high and 10 feet wide. Each of the two dip tanks have a capacity of 5000 gallons of coating material. Both are equipped with mechanical clarifiers.

Of course, it is highly desirable that an outfit such as this be practically independent of weather conditions, so

Continuous single strand-type oven and conveyor.

air is introduced in the baking compartment closely controlled as to temperature and purity. To accomplish this feat the air is supplied by power-driven fans which force it through steam coils where it is brought to a predetermined temperature and then passed over reed filters to remove dust and other impurities.

Thus it will be seen the degree of quality of the work depends upon the equipment used as well as the grade of material and the care taken to do the actual work. Even the air supply from the filter enters the oven room under pressure at three separate receiving points. Means is provided to determine the direction of flow within the oven which, of course, must be counter to the direction in which the work travels. This allows an interchange of heat between the air and the work and subsequently reduces the amount of fuel required to produce a given result. It also reduces the amount of smoke and fumes within the oven which results in the elimination of condensation within the oven, ideal baking conditions and a high degree of safety, for be the reader reminded that one of the factors which held this japan finish down for years was the explosion hazard present when the heavily coated parts were confined for baking in an oven not equipped with safety features and other refinements which have since been found necessary.

Fig. 6. Curves illustrating "A"-type Oven.

Much time and money has been spent in trying to make japan do the work of smoothing the metal upon the theory that the coating would flow into the uneven surface spaces and make it perfectly smooth. But this is an impossibility. The fact is that this type of finish depends upon the smoothness of the metal surface to begin with. If the surface is not smooth—before the coating is applied—then the japan finish will make the unevenness perfectly obvious and vice versa. In other words the finish will follow the contour of the metal.

Space will not permit of going into detail as to the sanding and cleaning of the metal prior to finishing nor into the subject of application via the various methods, such as dipping, tumbling and especially spraying for which there are as many different types of spraying outfits as there are articles to be sprayed.

There are also many types of ovens which may be heated by various means, gas, electricity, coke or fuel oil but the specifications which govern the design features of ovens may be listed as follows:

- Size of oven
  - Number and size of parts
  - Number of parts for each bake
  - Time of bake
- Temperature
  - Process and
  - Kind of material used for heating, gas, oil or electricity
  - Time of baking
- Heat capacity
  - Time
  - Load
  - Temperature

In spite of the remarkable progress made in japanning there is still much to be accomplished and a goodly portion of this is scientific research on the joint action between the metal and the coating. Very little basic research work has been done on japanning aside from getting by with results which are derived from actual experience in production and use. This is a very expensive way to experiment but happens to be about the only way progress has been made in this particular branch of the finishing field. Little, for example, is known regarding the coefficient of expansion of the finish in respect to that of the metal, aside from the guess that it is very close to that of steel.

Surface Coatings for

BY W. H.

NATURE conveniently and promptly provides an oxide coating on all aluminum exposed to the atmosphere even for an instant. Nature can be improved upon in this respect, however, for oxide coatings and surface coatings of other types can be applied to aluminum alloys, to give superior protection or interesting and attractive decorative effects. A review of the art in this field is presented by the author.—Junius D. Edwards.

OUTSTANDING among the metallurgical contributions to progress has been the development, within the past 20 years, of the lightweight, high-strength aluminum alloys. Concurrent with their diverse utilizations there arose a demand for surface coatings of 2 fundamental types; namely, (1) decorative and (2) protective. The widespread use of the so-called wrought alloys in the aircraft industry, where severe saline service conditions are frequently encountered, has naturally elevated the problem of protective coatings to one of major importance, since many of these alloys are susceptible to embrittlement resulting from corrosive attack, especially in the presence of chlorides.[1] It is the purpose of the present paper to review briefly the various coatings in use at the present time and to indicate, insofar as is possible, the relative merits of each, particularly with regard to the degree of protection they might be expected to afford.

For purposes of convenience surface coatings on aluminum alloys may be roughly classified into 3 groups: 1. Oxide coatings; 2. Metallic coatings; and 3. Organic coatings such as grease, paint, varnish, lacquer and enamel. It is of interest to note that research and theoretical considerations have played an important rôle in the production of satisfactory coatings, particularly those of the first two groups.

OXIDE COATINGS

Although it had been known for many years that aluminum was itself quite resistant to ordinary atmospheric conditions, and that this resistance was related to the natural presence of an adherent and relatively impervious oxide film, the protective merits of artificially produced oxide films received but little attention at the hands of investigators. Experiments as early as Faraday's time had revealed that the natural oxide films could be measurably increased in thickness by making the metal an anode in a suitable electrolyte. Cognizance was first taken, however, of the insulating properties of the artificially produced oxide films and their subsequent uses were practically confined to electrical fields, for example, in the construction of rectifiers, lightning arresters, condensers and the like.

The post-war development of aircraft resulted in intensive investigation of the alloys of aluminum for possible use in aeronautical fields. Heat-treatable alloys of the duralumin type appeared to offer unusually excellent adaptations for both interior and exterior aircraft parts. This initial optimism was replaced by extreme pessimism, in many instances, once the corrosion-embrittlement of the alloys was generally accepted as an established fact. In the efforts to effectively combat this corrosion the production of a resistant oxide coating was early recognized as an avenue of approach.

Numerous methods, both chemical and electrochemical, have been devised for the production of oxide films on aluminum and aluminum alloys. With few exceptions, coatings produced by electrochemical means i. e., anodization, afford better corrosion resistance than those obtained by purely chemical, i. e., simple immersion, methods.

The properties of the oxide films show considerable variation and are dependent upon such factors as the composition of the alloy to be treated, the composition and temperature of the solution employed, and, in the electrolytic processes, the applied voltage. The latter may range from a few volts to as high as 500 volts. A few of the films, in addition to their insulating and corrosion resistant properties, provide an excellent absorbent surface for dye, paint and oil, which renders them the more useful for purposes of decoration or protection.

The anodic coating developed by Bengough and Sutton[2] has proved one of the most satisfactory coatings from the standpoint of corrosion resistance and has probably had more extensive commercial use than any other. The electrolyte consists of a 3% solution of chromic acid, and it is regarded as necessary to keep the chlorine content equivalent to less than 0.2 g./l. NaCl and the sulphate content equivalent to less than 0.5 g./l. H_2SO_4. Specimens to be coated

are first cleaned free from grease with some solvent such as naphtha and are then washed in hot water.

The acid solution is frequently placed in a steel container, since the latter can serve also as the cathode. The recommended procedure is to control the bath voltage as to raise it gradually from 0 to 40 volts within 15 minutes, hold it at 40 volts for 35 minutes raise it to 50 volts within 5 minutes, and hold it at 50 volts for 5 minutes. The temperature of the bath should be held constant at 40° C., for the temperature apparently is a determining factor in the production of corrosion resistant films.

The Bengough process is applicable to the majority of the aluminum alloys. Copper in excess of 5% has a deleterious effect on the corrosion resistance, since the compound $CuAl_2$ is attacked more rapidly than the remainder of the surface, and gives rise to discontinuities in the film. The coatings obtained on the wrought alloys are usually more corrosion resistant than those on cast alloys. The films cannot be applied if the aluminum alloys are in contact with dissimilar metals, but good welds apparently offer no particular difficulties.[3]

Analyses have indicated that the oxide film contains chromium compounds equivalent to about 0.04 gram of CrO_3 per square meter, and the corrosion resistance of the film is attributed in part to their presence.[4] It has been estimated that the film is about 100 times as thick as that which forms naturally on aluminum. The metal undergoes a slight loss in weight in the coating process. The color of the film varies somewhat with the alloy treated. On alloys of the 17S type it is usually a pleasing greenish-gray; high silicon alloys yield a dull purple film.

In corrosion resistance the films produced by the chromic acid anodization have proved to be among the best of the oxide films. The films will retard the onset of corrosive attack under severe corrosive conditions for an appreciable, although relatively short, period. Under mild conditions of service, it will afford protection comparable with, and often better than, that of many paints. The capacity of the films for absorbing dyes such as alizarine orange or yellow, anthracene blue and Solvay green, is excellent, and makes it possible to obtain a variety of decorative effects.

Commentz[5] was among the first to recommend a cold concentrated sulphuric acid electrolyte for the production of a "strong coating." A process of anodization commercially known as "Alumilite"[6] is reported to employ a solution containing about 25% by weight of sulphuric acid. A 6% antimonial lead alloy serves as the cathode. Anodization is accomplished by applying from 12 to 15 volts, at temperatures ranging from 20° to 30° C., for periods of from 10 to 40 minutes. The "Alumilite" oxide film has been used principally for decorative purposes. The film absorbs both paints and dyes and over 60 shades of colors are said to be available. The "Alumilite" film offers unusually good resistance to abrasion and is reputed to have a Bierbaum scratch hardness value equivalent to that of a medium hard steel. Its corrosion resistance is comparable with that of the oxide film obtained by the Bengough process.

The Stafford-O'Brien[7] and Gower-O'Brien[8] anodization processes, which have been used commercially in Europe to some extent for purposes of protection, also employ an electrolyte of sulphuric acid. In addition to the acid the Stafford-O'Brien solution contains a chloride while the Gower-O'Brien solution utilizes other salts such as sodium dichromate and sodium hyposulphite. Rackwitz reports that aluminum alloys anodized by the latter method have been used successfully aboard ships. The Stafford-O'Brien process is reported to produce satisfactory films on aluminum alloys containing more than 5% of copper.

The anodization processes just reviewed are among the best so far developed for the production of corrosion resistant films. Other electrolytes may be used to obtain oxide films, among them sodium hydrogen phosphate,[9] borax,[10] sodium oxalate,[11] fused sodium nitrate, ammonium hydroxide and ammonium sulphide.[12] Experience has indicated, however, that these films are inferior to the above-mentioned coatings in their corrosion resistance, although they may be utilized for purposes of decoration or insulation.

It has already been stated that it is possible to produce oxide films on aluminum alloys by simple immersion in suitable solutions. Dilute solutions of nitric

acid, phosphoric acid or sodium hydroxide may be used and, although the resulting films are resistant to only very mild corrosive conditions, they can be used with considerable success to obtain good adherence of paint or varnish coatings.

A method developed by Jirotka[13] consists in immersing the specimens in a solution of chromates or dichromates and one or more salts of a heavy metal (usually carbonates). The treatment is usually carried out in enameled vessels at temperatures slightly below boiling and for periods from a few minutes to an hour or more. The compositions of the Jirotka baths, of which there are more than 80, show rather wide variations. A typical solution which produces a film somewhat resembling in appearance that obtained by the Bengough process contains 5 g./l. chromium sulphate, 25 g./l. potassium carbonate, 25 g./l. sodium bicarbonate and 5 g./l. potassium dichromate. The Jirotka films have been used to a considerable extent commercially, principally for decoration and finishes resembling copper, bronze, gold, silver and nickel, are readily obtained. The plain films are more corrosion-resistant under mild conditions than those produced by most other immersion methods. They are thinner than films obtained by electrolytic methods, although they show fair resistance to abrasion.

McCulloch[14] has recently developed a method which yields dead-white coatings on aluminum and dull gray coatings on its alloys. The method consists in immersion of specimens in a boiling solution containing 10 grams of unslaked lime and 10 grams of hydrated calcium sulphate per liter. The coatings are comparable in their corrosion resistance to those obtained by the Jirotka method but are less resistant to abrasion and can be rubbed off with a pencil eraser.

METALLIC COATINGS

Recent experiments by Akimow[15] have indicated that the metals best suited for the protection of aluminum alloys under saline conditions are zinc, aluminum, cadmium, magnesium and manganese. This Russian investigator measured the potential differences set up in dilute solutions of sodium chloride with and without additions of hydrogen peroxide. Of the above metals, zinc, aluminum and cadmium appear to be the only ones capable of practical application.

The methods of obtaining metallic coatings on aluminum alloys include electrodeposition, metal spraying and integral alloying with the base metal. The use of metallic coatings other than aluminum or an alloy of similar density may not always be feasible in aircraft because of weight considerations.

Aluminum alloys have been electroplated with a number of metals since Work[16] performed his extensive work in developing suitable methods of plating. With the possible exceptions of zinc and cadmium coatings, however, electrodeposited coatings have generally failed to give satisfactory protection under severe corrosive conditions. Many deposits which have an excellent superficial appearance when new, exhibit a tendency to blister and peel after short periods of service in the presence of moisture, which difficulty has been traced to discontinuities such as "pin-holes" in the coatings.[17]

Cournot[18] and Cazaud[19] have developed a method termed "cementation" in which aluminum alloys are first plated with relatively thick copper deposits and are then heated to temperatures of 545° to 620° C. in a neutral atmosphere. The treatment results in an adherent alloyed coating. Almost any finish can be secured by plating other metals over the copper. Quite aside from any detrimental effect that the somewhat drastic heat-treatment may have, weight considerations might limit the utilization of coatings of this type in aircraft.

The commercial applications of electrodeposited metallic coatings, with or without subsequent "cementation," seem to be limited, for the most part, to the production of decorative effects. Electrodeposition of aluminum, the most desirable coating, is not yet practicable. Protection from corrosive attack is restricted to conditions of mild exposure except for coatings such as zinc and cadmium. Coatings of nickel, copper or chromium are not satisfactory because they are or become porous and the resulting electrolytic action accelerates the attack of the base metal.

What has been said of electrodeposited coatings applies, in general, to metal-sprayed[20] coatings on aluminum alloys. Coatings of aluminum or zinc sprayed by the Schoop process afford excellent protection for relatively long periods under severe saline conditions. Zinc coatings, however, are not satisfactory in sulphurous atmospheres.

Patented Aluminum Tank Truck Body.

Alloying of the base metal and the coating does not occur in the metal spray process, the sprayed metal being "linked" entirely mechanically to the surface. For this reason a preliminary surface roughening, as by sand-blasting, is essential for good adherence. Sand-blasting of sheet material frequently results in a lowering of the tensile properties of the metal and heat treatment is necessary to restore them to their original values. The excellent protection afforded by sprayed aluminum coatings makes their use commercially feasible. Consideration of the theoretical potentials involved has led to the application of metallic coatings, by alloying them directly upon the base metal. The degree of protection thus afforded is vastly superior to that of coatings produced by any other method with the possible exception of sprayed metal.

An alloy sheet marketed under the trade-mark "Alclad"[21] is now manufactured in America. It con-

sists of an aluminum alloy (usually 17S), to both sides of which a layer of very pure aluminum is alloyed. The thickness of the aluminum layer on each side averages about 5% of the total thickness of the sheet. In the heat treated condition, the tensile strength and yield point of the coated sheet are from 5 to 10% lower than those obtained on sheet of the same gage composed entirely of duralumin. Elongation values are the same for both. The superior corrosion resistance, however, more than compensates for the slight lowering in strength where the latter is not essential.

The layer of aluminum is quite resistant to damage. When such does occur, however, the potential difference set up in the presence of moisture favors attack on the aluminum coating and the base metal remains unattacked even though relatively large areas, for example, 1/4 inch in diameter, are exposed. So long as the attack is confined to the coating, the material suffers no appreciable loss in tensile properties. The corrosion-resistance of Alclad sheet is exceptionally good under conditions of repeated flexural stress, which is an evidence that the adherence of the aluminum coating is much superior to that of other coatings.

In Germany there is manufactured an alloy termed Allautal, in which the Lautal alloy is fabricated with an integrally alloyed surface layer of pure aluminum as in the case of Alclad sheet. Another German product known as Duralplat[22] consists of duralumin similarly coated with a copper-free aluminum alloy. Duralplat was developed on the theory that if the potential difference between the surface coating and the base metal was less than that between pure aluminum and the base metal, the attack on the surface layer would proceed more slowly. Duralplat is reported to offer corrosion resistance as good as, if not better than Alclad sheet, although no definite data have yet appeared in the literature.

Aluminum Office Chair Finished to Resemble Wood with Polished Aluminum Strips on Legs.

ORGANIC COATINGS

Paints, varnishes, greases, etc., have been used extensively for both decoration and protection for many years. Their ease of application by simple brushing, spraying or dipping, necessitates the use of comparatively little equipment, and adds to their desirability. On the other hand, most coatings of this type are permeable in some degree to moisture which may react with the base metal and lessen the adhesion of the coating. They are also susceptible to deterioration by sunlight and weather. The relative inability of the coatings to withstand mechanical injury is also detrimental.

Such coatings afford practically unlimited scope for decorative effects and a certain degree of protection under rather mild corrosive conditions. Where protection is the paramount object, a coating must be selected that is adapted to the particular conditions under which it is to be used in service.

The requirements for coatings on aircraft are difficult to fulfill in the case of paints or varnishes. Low weight per unit of area is, of course, a prime requisite. Good elastic properties which foster continuous and permanent surface adherence under vibration, are likewise essential. Add to these the ability to withstand rapid temperature variations, the influence of ultra-violet rays in the higher altitudes, climatic conditions ranging from the frigid to the torrid, and moisture contacts as severe as salt spray or seawater, and the difficulties in selecting suitable organic protective coatings become apparent.

The adherence of paint to an untreated duralumin alloy surface, immersed from time to time in water, is usually poor, and hence preliminary treatment of the surface is imperative and may be as important as the selection of the paint. Mechanical roughening, by means of sand blasting or scratch brushing, has proved inferior to mild chemical treatment. Mere removal of grease from an unroughened surface by solvents such as benzene is not very effective, since paints applied to surfaces of this type tend to develop "blisters" in the presence of moisture. The blisters contain both water and gas, the latter exerting a pressure which tends to enlarge the blisters and to strip the paint from the surface.

When protection against corrosion is the paramount object, primers should be chosen with that end in view. "Red oxide," zinc chromate, and mixtures of zinc chromate and bituminous paint, and aluminum-pigmented spar varnish have been shown by experience to be among the best. The application of 2 additional coats of paint, rather than only one, is also to be recommended wherever possible.

Only a few organic coatings remain stable for long periods under severe corrosive conditions. Certain bituminous or asphaltum paints are quite impervious to moisture, possess excellent adhesive qualities, afford good protection, and have been used with success on parts submerged continuously in salt water. These paints are prepared with coal-tar solvents, such as naphtha or benzene. Their chief disadvantage is their susceptibility to damage by abrasion and their lack of resistance to sunlight.

It has been found that the addition of pure aluminum bronze powder, about 140 mesh, to suitable paints

The all-metal airship ZMC-2, built by the Aircraft Development Corporation, has an internal frame made from aluminum alloy sheet and tubing. The entire gas bag is enclosed in a shell of .0095 inch "Alclad" sheet.

and varnishes markedly increases their imperviousness to moisture. The powder is composed of minute flakes and tends to form a thin, practically continuous film of aluminum at the surface of the vehicle. Good grades of long oil varnish are made especially as vehicles for aluminum powder, and the resultant paint has proved durable and efficient under severe conditions of exposure.

Edwards and Wray[23] have shown that the moisture-proofing efficiencies of unpigmented long oil varnishes, which average about 60% in three coats can be raised to as high as 96% by pigmenting with aluminum powder. Aluminum pigmented bituminous paints also have moisture-proofing efficiency values of about 98%. Aluminum pigmented coatings exhibit a high degree of opacity and reflectivity, the former being of considerable importance in that it prevents the transmission of ultra-violet rays and thus adds measurably to the protective qualities and life of the vehicle.

Enamels which do not require "baking" have been used for purposes of protection, and good results have been obtained with 2 coats of Navy gray enamel on a red oxide primer. Coatings which require baking are not to be recommended, since heating at temperatures in excess of 100° C. frequently renders aluminum alloys, especially when in sheet form, more susceptible to corrosion. For castings not subjected to vibratory stresses, immersion in an aqueous sodium silicate solution[24] having a specific gravity of 1.1, followed by baking at 120–175° C., has afforded good protection under mild conditions and gives a coating to which paints adhere well.

COMBINATIONS OF COATINGS

The ability of certain oxide films to absorb paint vehicle, varnish and grease has made it possible to obtain combinations which render very satisfactory service under severe conditions of exposure. The resistance of the absorbed coatings to hygroscopic action is increased many-fold; blisters, when formed, remain comparatively small in size, as the adherence between the oxide film and the paint is usually sufficient to counteract the spreading or stripping tendencies already noted. It should be stated, however, that the best of such combinations of coatings has not yet resulted in the same degree of protection attainable with coatings of the Alclad sheet type.

The Bengough oxide film is particularly suited for the application of paint, varnish and grease. Films produced by the Jirotka method likewise form a very good base for organic coatings, but are somewhat inferior to the Bengough films in this respect. Milburn[25] has pointed out that excellent protection may be obtained on aluminum alloys exposed continuously to salt water by first anodizing, painting with an aluminum-pigmented vehicle, and then applying an additional coat of beeswax mixed with grease. It is also possible to use combination coatings with alloys of the Alclad sheet and Duralplat types Excellent protection for prolonged periods is to be expected if, for example, an Alclad sheet specimen is treated anodically and then painted or greased.

A series of weather-exposure tests is now being conducted by the Bureau of Standards to obtain data on the efficiency of various protective coatings. Some of the specimens are suspended from the side of a pier at Hampton Roads, Va. and are about 3 feet above the sea-water at high tide. The specimens are, therefore, exposed to temperate sea-coastal atmospheric conditions with an occasional wetting by sea water. The specimens shown in Figs. 1 and 2 form a part of these tests. Six of the specimens (a-f) were exposed for a period of 3 years and specimen (g) was exposed for $3^1/_2$ years.

The specimens shown in the figures were all 14-gage (0.064 inch thick) sheet duralumin material. With the exception of specimen (*a*), which was quenched in ice water, the specimens were quenched in boiling water from temperatures of 500–510° C. The individual specimens were given surface treatments, prior to exposure, as follows: (*a*) none; (*b*) none; (*c*) Jirotka immersion followed by a dip in a solution of lanoline in benzene; (*d*) Bengough anodization and lanoline dip as in (*c*); (*e*) cleaned free from grease with ben-

Fig. 1. Surface appearance of Duralumin specimens given various coatings, after exposure for approximately 3 years to the weather at Hampton Roads, Va. The surface treatments were as follows: (a) and (b) none;—(c) Jirotka + grease (d) Bengough anodization + grease; (e) aluminum pigmented spar varnish; (f) Bengough anodization + aluminum pigmented spar varnish; (g) Alclad material. $1^1/_3\times$.

zene and given three coats of aluminum pigmented spar varnish; (*f*) Bengough anodization plus 3 coats of varnish as in (*e*); (*g*) Alclad sheet. Specimens (*a*) and (*b*) are included to illustrate the tremendous effect which heat treatment may have in determining whether or not the corrosive attack will be intra- or inter-crystalline in nature. The heat treatment plays a definite rôle in the production of corrosion resistant material and quenching should always be carried out in *cold* water. Specimens (*c*) to (*g*), inclusive, were purposely quenched in boiling water so that corrosion of the intercrystalline type would occur immediately following coating "breakdown;" the presence of this type of attack produces a noticeable loss in tensile properties.

It may be seen in Fig. 1 that at the end of the 3 year exposure period there was no marked difference in the surface appearance of specimens (*a*), (*b*), (*c*) and (*d*). Specimen (*e*) was obviously less severely attacked than any of the former, but the paint coating had completely weathered away. On specimen (*f*) the coating had commenced to show first evidences of "breakdown" but was still practically unattacked, thus illustrating the benefit to be derived from prior anodic treatment when applying paints. The surface appearance of specimen (*g*) indicated the presence of corrosive attack. The surface appearance of Alclad sheet does not, however, serve as a very reliable criterion of the extent or depth of penetration of corrosive attack because the pure aluminum layer itself may be severely attacked while the duralumin base remains unattacked.

The appearance of the specimens under the microscope is shown in Fig. 2. Note the decided difference in both the type and depth of penetration of corrosive attack in specimens (*a*) and (*b*). That the oxide film-grease combinations retarded the initial corrosive attack for an appreciable period is evident from (*c*) and (*d*). The aluminum pigmented spar varnish on the unanodized surface of specimen (*e*) afforded protection comparable with that of the oxide-grease combinations. The protection afforded by the paint applied to the anodized surface of specimen (*f*) was vastly superior and corrosion had just begun after 3 years' exposure. The corrosive attack on specimen (*g*) was entirely confined to the aluminum coating, which had not yet been penetrated through.

The tensile properties serve as approximate criteria of the damage done by corrosion. Before the exposure tests specimens (*a*) to (*e*), inclusive, had an ultimate tensile strength of approximately 60,000 lbs./in.^{2} and an elongation in 2 inches of about 20%. In general, the loss in tensile strength due to corrosion was approximately 10% and that in elongation was more than 50%. No appreciable loss in tensile strength and a small reduction in elongation was noted for specimen (*f*). The elongation before exposure of specimen (*g*) was also 20% and its strength was approximately 56,000 lbs./in.^{2} It is especially significant that after over 3 years' exposure only the Alclad sheet showed no loss whatever in tensile properties.

CONCLUSIONS

The development of decorative and protective coatings for aluminum alloys has kept pace with the development of the alloys themselves. The number of

Fig. 2. Microstructure of cross-sections of specimens shown in Fig. 1. Specimens (a)—(f) are in unetched condition. Specimen (g) was etched to differentiate the pure aluminum coating from the base metal; the corrosve attack has not penetrated the coating. (Originally photographed at 250× and subsequently reduced to 100×.)

Aluminum Van Body Painted.

methods of coating available make it possible to exercise considerable choice in selecting the most satisfactory coating for the desired service. For purposes of corrosion prevention, in particular, many coatings afford sufficient protection for mild conditions of exposure. For severe conditions of exposure, the choice of protective coatings becomes more limited. Specially fabricated materials of the Alclad sheet or Duralplat types, however, assure protection for relatively long periods under severe corrosive conditions. Where their use is impracticable, suitable paint coatings, applied to previously anodized surfaces, afford excellent protection for shorter periods.

Evaluation of Clear Nitrocellulose METAL LACQUERS

BY G. C. SHAKOUR AND L. W. MUNCHMEYER*

THERE are several well-known types of lacquers for metal protection. This article describes the qualities of four types and tells how nitrocellulose lacquers, the most important member of the group, can be tested and evaluated.

CLEAR metal lacquers are applied to metals as a protective or ornamental finish and have been an industrial commodity for many years. Since the metal working art has achieved such popularity in the household field, the uses for clear metal lacquers have increased immensely. Now the major part of the products of the builder's hardware, lighting fixtures and metal novelty industries, as well as many other miscellaneous metal articles, are coated with clear metal lacquers.

It is obvious that with this increasing demand for clear metal lacquers that various types of products will be found and developed to meet the particular requirements as they arise. The most important types of clear metal lacquers and their variations being used by the industries are:

I. Lacquers Manufactured from Phenol Condensation Products (Bakelite).
II. Lacquers Manufactured from Condensation Products of Polyhydric Alcohols and Polybasic Acids and Their Modifications (Glyptals and Resyls).
III. Gum Lacquers (Water Dip Lacquers).
IV. Nitrocellulose Lacquers.
  (a) General Purpose Lacquers.
  (b) Silver Lacquer.
  (c) Special Products.

Lacquers Manufactured from Phenol Condensation Products

Lacquers manufactured from phenol condensation products are best adapted for use where a very hard, durable, protective coating is required, and which is unaffected by alcohols, alkalies and acids in common use. However, there are some disadvantages to this type of lacquer. Among these are, pronounced yellowing of film on aging or exposure to sunlight, discoloration of some work due to chemical reaction between the wet lacquer and the metal being coated, difficulty of application and special equipment for handling.

Lacquers Manufactured from Condensation Products of Polyhydric Alcohols and Polybasic Acids and Their Modifications (Glyptals and Resyls)

This type of clear metal lacquer is used in place of nitrocellulose lacquers where greater durability, wear resistance and flexibility is required. Most lacquers of this type, however, like the phenol condensation products have a greater tendency to yellow and are generally darker in color than most well-balanced, high grade nitrocellulose lacquers. They are also more difficult to apply and require a longer drying period.

Gum Lacquers

Gum lacquers are the most inexpensive type of the entire group of clear metal lacquers of commercial importance to-day and are characterized by their lack of durability. They are used chiefly in coating inexpensive metal articles to prevent tarnishing and corroding of the articles until they are sold to the ultimate consumer. This type of lacquer is suitable for coating dry or water wet metal articles.

Failure on Outdoor Exposure.

Nitrocellulose (Cellulose Nitrate) Clear Metal Lacquers

Nitrocellulose lacquers are commercially the most important member of the group in the field of clear metal lacquers, and are used almost entirely for coating the more expensive metal goods. This class designates lacquers that usually contain appreciable proportions of natural or synthetic gums in addition to the nitrocellulose. High grade clear nitrocellulose metal lacquers are easy to apply, resistant to yellowing and non-corrosive. They have, however, less durability if the article is to be subjected to outdoor exposure, and less wear resistance than lacquers manufactured from phenol condensation products and also from condensation products of polyhydric alcohols and polybasic acids.

In view of the commercial significance of nitrocellulose lacquers in the clear metal lacquer field, we shall pass over the other members of the group without further comment and present the most important properties of nitrocellulose metal lacquers and a system of tests which will enable the consumer of these commodities to select a high-grade product which is best adapted for his work.

The most important properties of nitrocellulose clear metal lacquers are as follows:

1. Minimum crystal spotting under the lacquer film on oxidized finishes.
2. Minimum stain spotting under the lacquer film on cast work.
3. Maximum resistance to the deteriorating effect of outdoor exposure.
4. Maximum adhesion to the metal.
5. Maximum hardness without sacrifice of flexibility.
6. Maximum flexibility.
7. Minimum discoloration of film on aging.
8. Maximum tarnish resistance (green drip).
9. Perspiration resistance.

DESIRABLE PROPERTIES OF A METAL LACQUER

Minimum Crystal Spotting under the Lacquer Film on Oxidized Finishes

Crystal spotting is a type of failure that occurs only on the surface of metals having a sulphide film (generally referred to as oxidized finishes) and a coating of lacquer or similar material. The spots are formed by the permeation of the coating by volatile sulphur compounds which react with the metal to form brown or black crystals of cuprous sulphide. The photomicrograph shows the typical appearance of crystal spotting on oxidized finishes.

Hydrogen Sulphide Test:

The Principle of Test—Research work has shown that the degree of susceptibility of the lacquer film to the penetration of the volatile sulphur compounds can be determined by the rate at which hydrogen sulphide (H_2S) gas permeates through the lacquer film. Hydrogen sulphide gas and other volatile sulphur compounds have a great affinity for activated copper and react with it to form black copper sulphide. If copper panels are coated with various lacquers and subjected to the gas, the degree of protection given the copper (represented by the bright-

ness of the panel shortly after exposure to the gas) affords a measure of the impermeability of a lacquer film relative to another.

Methods of Test—Soft rolled copper plates are heated to red heat in an oxidizing flame and reduced by immersing the plates in alcohol. After cooling (approximately one minute) the plates are removed from the alcohol and wiped dry to obtain a bright copper surface. Two bright copper plates are dipped in each of the lacquers under test, air-dried for $^1/_2$ hour and baked for 15 minutes at 65° C. (149° F.). After drying, the plates coated with the various lacquers under test are exposed to an atmosphere of hydrogen sulphide under slight pressure. After 30 minutes' exposure, the plates are compared in brightness with a panel which had not been exposed to the gas. The least discolored panel indicates the greatest impermeability of the lacquer coating to hydrogen sulphide and other gaseous sulphur compounds.

Minimum Stain Spotting under the Lacquer Film on Cast Work

Stain spots are a type of failure that occur only on porous metals (usually cast work or work pitted by the cleaning solutions) which have been subjected to the action of cleaning, pickling or plating solutions. In preparing the metal prior to lacquering, part of the solutions become entrapped in the pores of the metal and on evaporation are left as dry, unreactive compounds. Upon subsequent exposure of the articles to a humid atmosphere, the deliquescent compounds in the pores of the metal are reactivated by moisture and exude from the pores, staining the metal. Stain spotting may occur either on oxidized or unoxidized, plated or unplated, lacquered or unlacquered metal. The photomicrograph shows the typical appearance of stain spotting on porous metal.

Test for Stain Spotting:

As lacquer films which are highly impermeable to water vapor, moist corrosive gases, and are resistant to alkaline chemical compounds have been found to have good resistance to stain spotting the rate of failure under these conditions has been set up as an index to stain spotting.

Method of Test—The test consists of suspending lacquered brass panels (same thickness of coating) over an oxidizing bath containing 9 parts of ammonium hydrosulphide (NH_4HS), 4 parts liver of sulphur and 435 parts of water, contained in a closed gas desiccator. An oxidizing bath such as that generally used in the plating industry will be quite satisfactory for use in this test. The test is run until some of the lacquers under test fail. Some lacquers fail in 20 minutes while others will stand the corrosive action of the moist vapor for several days. The length of time required for failure of the various lacquers under test is a measure of the impermeability of the lacquers to the corrosive action of the moist vapors and, therefore, is also a measure of the lacquer's resistance to stain spotting.

As can readily be seen from the photomicrographs shown above some very interesting data can be obtained concerning the mode of failure of the different

Oxidizing tank test apparatus developed by du Pont Laboratories, and lacquered panels subjected to this test.

lacquer films when subjected to this test. Though a microscopic study was made of these panels the mode of failure can easily be studied with the naked eye. The lacquers shown above are the same lacquers that were in the hydrogen sulphide test as well as in the other tests that will be illustrated. Panels (a), (b) and (d) were subjected to the Oxidizing Bath Test for 30 hours. Panel (c), which had withstood the dry Hydrogen Sulphide Test quite well, failed miserably in 15 minutes in this test.

Photomicrographs of brass panels lacquered with Lacquers (a), (b), (c) and (d) after having been subjected to the Salt Spray Test for 30 hours.

Maximum Resistance to the Deteriorating Effect of Outdoor Exposure

Durability on outdoor exposure is one of the most important properties of metal lacquers and is a true criterion of the protective power of any metal coating. Failure on outdoor exposure may result in either one of three ways described below and shown in the illustration:

First, Corrosion of the Metal Surface but Film Only Slightly Discolored.

This particular type of failure is characteristic of lacquers containing only nitrocellulose as the film forming ingredient. The corroded areas result either from the penetration of the film by corrosive gases or from the loosening or rupturing of the film by the dust particles of the air, leaving the metal exposed and subject to rapid corrosion. Lacquers which contain suitable resins have far greater adhesion and resistance to the abrasive action of dust particles. Panel (c) shown above represents failure of this type. Panel (a) represents a perfect panel and is used in this photograph only for comparative purposes.

Second, Corrosion of the Metal Surface and Film Greatly Discolored.

This type of failure is characteristic of lacquers having a poor combination of nitrocellulose and resins and is generally considered to be the worst type of failure than can result. This type of failure is shown distinctly by panel (d).

Third, Yellowing of Film.

It is a well-known fact that all nitrocellulose products have a slight tendency to yellow with age and that certain other lacquer ingredients tend to increase this yellowing. The lacquer technician can prevent the objectionable failures represented by panels (c) and (d). Slight yellowing, however, cannot be entirely eradicated but can be minimized by judicious formulation and very critical testing. Although slight yellowing must be classified as a failure, it is far less objectionable than the other two types since the metal is still fully protected and looks well. Panel (b) represents this type of failure.

Salt Spray Test:

The salt spray test, while it primarily serves as an indication of the resistance of lacquered metal to corrosion when subjected to salt vapor, proves also to be a further means of determining the impermeability of lacquer films to moisture. This test, therefore, offers to some extent a means of determining the relative resistance of lacquer films to the deteriorating effects of outdoor exposure.

Principle of Test—The rusting or corrosion of coated metal is due to moisture and air penetrating the coating. The use of a salt spray will show up these penetrations very quickly due to the corrosive action of salt water on metal. This must be considered as an accelerated test for a lacquer which must withstand exposure to high humidity at ordinary temperature, as well as for a lacquer that must withstand exposure to a salty atmosphere or to contact with salt water. The salt vapor thus provides a sensitive test for metal coatings subjected to these conditions and the amount of rusting or corroding occurring is an index of the relative results that would occur under such exposure in service.

Method of Test—The material to be tested is applied to shiny brass plates (2″ × 4″) by spray or dip methods. After drying thoroughly, the plates are then placed in grooves of a wooden block which holds them in an upright position, and the entire block holding the plates is then placed in a salt spray cabinet. The spray consists of a 20% salt (NaCl) solution which is atomized by a 60-lb. air pressure. The relative position of the plates is of no importance because of the uniformity of the salt mist. The panels are examined every few hours (any convenient time interval) for failure of the lacquer coating by corrosion areas on the metal. The length of time required for failure and the extent of corrosion of the metal is a measure of the relative resistance of various lacquers under the established conditions of test.

Adhesion, Hardness and Flexibility

The properties of adhesion, hardness and flexibility are important properties of a metal lacquer. These properties are not entirely independent of each other as they might appear, but are to some extent related insofar as the factors governing any one of these properties have at least some effect on the other two.

Standard Knife Test for Adhesion and Hardness—The method consists of dipping (2″ × 4″ × .008″) brass plates in the thinned lacquers under test and then allowing the panels to air-dry for $^1/_2$ hour followed by a bake for 15 minutes at 60° C. (140° F.). After cooling, the film characteristics are tested by holding a scalpel on the surface of the film and at right angles to the direction of movement. The arm is drawn toward the body and with a slight pressure the lacquer film is cut in such a manner as to get between the film and the metal surface. In this way the hardness and adhesion of a lacquer may be determined and evaluated relative to another lacquer which is tested in parallel. The results of the knife test are affected greatly by the variable human factor, but with experience one is able to determine the relative hardness and adhesion of a lacquer better by this test than by most other methods of testing now in use.

Method of Testing for Flexibility—In testing for flexibility brass panels are prepared in the same manner as for testing for adhesion and hardness except that the panels are baked for $^1/_2$ hour instead of 15 minutes. After cooling, a panel is held between the thumb and index finger of both hands and is bent sharply upon itself (180°). The panel is again straightened and the operation is repeated 5 times. The lacquer film is then examined for flaking, which is an indication of lack of flexibility (not adhesion). A well-balanced lacquer, if prepared as mentioned previously, should show no flaking after bending five times. Baking excessively may cause flaking even with good lacquers.

Crystal spotting on oxidized finish.

Stain spotting on porous metal.

Discoloration of Film

Discoloration of lacquer films has already been discussed under the subject of durability.

Tarnish Resistance (Green Drip)

The chief concern of a lacquer consumer in respect to the acidity of a lacquer is to obtain a lacquer which will stand up well under all other tests and which will not form green drip (due to excessive acidity) on his work.

Method of Determining Acidity of Lacquers—Store bright strips of copper of the same surface area in contact with a definite quantity of each of the lacquers under test. The amount of discoloration (green) of any solution and the darkening of the copper strips may be taken as a measure of its acid content. The test should not be prolonged over 24 hours as results obtained beyond this time limit are of no value.

Perspiration Resistance

It has been observed that the coatings on parts of articles which are constantly handled wear through much faster than similar coatings which receive greater actual wear but which do not come in contact with perspiration. Coöperative tests conducted in conjunction with the Bell Telephone Laboratories reveal that nitrocellulose lacquer films subjected to the following test fail in the same order as did similar lacquers when subjected to practical tests conducted by the Bell Telephone Company.

Method of Test—The test consists of coating (dip or spray) any convenient size brass panels with the lacquers under test and drying the panels for 12 hours at 65° C. After this drying period, filter papers wet with oleic acid are placed on the lacquer films and the panels are then stored at 65° C. The number of hours it takes oleic acid to soften and wear through the lacquer films is taken as a measure of the resistance of the various lacquers to perspiration. It might be mentioned at this point that no nitrocellulose lacquer film has yet been found which has outstanding resistance to perspiration as well as being entirely satisfactory in all of the other important properties of metal lacquers.

THE SELECTION OF AN APPROPRIATE LACQUER

In selecting a lacquer which is best suited for finishing certain work, the lacquer consumer should make a careful analysis of the conditions to which his lacquered metal articles will be subjected and then select the tests which will tell him when he has a lacquer which will withstand those conditions. It is obvious that a general purpose metal lacquer, for instance, must rate high in all of the above mentioned tests. Certain silver lacquers might only need to be tested for adhesion, hardness and color, while still others might have to withstand more severe conditions and this will require a lacquer of the general purpose type. Occasionally metal lacquers will be required to meet certain unusual conditions. In such cases special lacquers are designed to fulfill these needs and the lacquers developed are classified as special products.

THE RATING OF NITROCELLULOSE METAL LACQUERS

The rating of nitrocellulose metal lacquers is probably the best way of selecting from a number of lacquers under consideration, the lacquer which will give the metal the greatest protection and keep it looking well for the longest period of time. It also provides an easily intelligible, permanent record of the results of tests on various lacquers.

In rating metal lacquers the properties may be divided into three groups: (*a*) ratable properties, (*b*) minimum requirements, (*c*) cost consideration. The properties put into group (*a*) are those considered of primary importance. Lacquer properties in this group

will be judged on a numerical rating basis. Properties placed in group (*b*) are considered of secondary importance. Lacquers must possess the properties in group (*b*) to a certain degree, which are considered as minimum requirements or be discarded as unfit for use.

Each property in group (*a*) is assigned a factor from 0 to 100 indicating the amount of importance attached to that particular property. The sum of these values should be 100. All lacquers will be rated in each of these properties on the basis of 0 to 10, and the rating should be multiplied by the importance factor. The sum of the products obtained will constitute the net rating of the lacquer. The properties of metal lacquers which should always be placed in group (*c*) are those which affect the unit finishing cost.

EXAMPLE

GROUP A	Importance Factor	Lacquer X	Product	Lacquer Y	Product
1. Resistance to Stain Spotting	15	9	135	6	90
2. Resistance to Crystal Spotting	10	8	80	8	80
3. Resistance to Effect of Outdoor Exposure	20	9	180	7	140
4. Resistance to Salt Vapor	12	5	60	5	60
5. Resistance to Discoloration of Film	18	7	126	5	90
6. Tarnish Resistance	10	6	60	6	60
7. Hardness	15	8	120	10	150
Net Rating			761		670

GROUP B—MINIMUM REQUIREMENTS

1. Adhesion
2. Color of Solution
3. Flow
4. Flexibility

GROUP C—COST CALCULATIONS

1. Blush Resistance
2. Percent Total Solids (Non-Volatile)
3. Thinner Tolerance

THE IMPORTANCE OF CLEANING OF METAL PRIOR TO LACQUERING

The selection and use of a high-grade metal lacquer will not always insure a successful finish, for the cleaning of metal is one of the most important, though often neglected phase in the lacquering of metal articles. The veracity of the statement that "for a trouble-proof finish start at the bottom" cannot be denied. The successful use of a high grade metal lacquer will depend directly upon the kind of cleaning the metal receives prior to the lacquering operation. Proper cleaning is the complete removal of all foreign matter from the surface and pores of the metal.

Although improper cleaning of metal prior to lacquering has a deleterious effect on all properties of a metal lacquer the properties of resistance to stain spotting, adhesion and hardness are most noticeably affected. No clear metal lacquer of any type has yet been developed which will completely prevent the stain spotting on cast work unless the castings have been cleaned satisfactorily.

There are many so-called greaseless buffing compounds used in buffing metals which are subsequently lacquered without cleaning in any way. Although these compounds generally clean up extremely well and leave the metal bright, it has been shown that most of the so-termed greaseless buffing compounds leave a slight amount of grease on the metal. This quantity of grease is often sufficient to destroy the adhesion of the lacquer to the metal and sometimes soften or imbrittle the lacquer film. Quoting from a letter written by a well-known manufacturer of greaseless buffing compounds—"We are very dubious if you will ever have very good success by lacquering surfaces that have been buffed and not cleaned. Regardless of the quality of the buffing composition used there is certain to be a very small amount of grease substance left on the work. It would appear to us that to do a perfect lacquering operation, the surfaces should be chemically clean. It is considered doubtful if the savings which are to be made by deleting the cleaning operation would not be more than offset by rejected work."

Editorial Comment continued from Page 317

courage rather than discourage people who were trying to do research in spite of handicaps.

His kindly, broad-gage attitude may well have made a lot of difference in encouraging the youngsters to go on in science while unfriendly criticism might have turned them into real estate agents.

We are not suggesting that erroneous results or questionable conclusions should not be questioned. They certainly should be, but it can be done in a friendly fashion. Those who are inclined to forget that a scientist should be a gentleman, might well study the published discussions of the late Dr. H. M. Howe, or, among contemporaries, of Dr. Jeffries and Prof. H. F. Moore. They express criticism when it is called for, but never in unfriendly fashion. Criticism of an unfriendly nature might well be reserved for crooks, four-flushers and those who attempt to use technical meetings for blatantly advertising purposes,—though if the Papers Committee is on its job, papers from such sources will not be presented anyway.

Some people are born friendly, and go through life constantly acquiring the good will of their co-workers and acquaintances. With others, this facility has to be developed. If one will figure that perhaps at some future day, he may want a favor from a man whom he is tempted to treat in an unfriendly fashion and that such a man, even though not as yet in a position to grant any favors may some day work himself into such a position, one's attitude may gradually change, and one's ability to gather goodwill may increase.

There are no school or college courses in this, though it can be taught by example of, and contact with, friendly personalities. It is, nevertheless, a matter to which the young scientist might well devote some thought and self-examination, for on few other qualities does his success so much depend.—H. W. GILLETT

Plating on Zinc Die Castings

BY E. A. ANDERSON* AND E. J. WILHELM*

ZINC is being successfully plated on an extensive scale. Nevertheless there are two reasons why not all plating has been satisfactory. One is a lack of adequate thickness of coating. The other is lack of knowledge of the proper method for plating upon zinc.

The first fault may be due to the use of improper methods or to cost-cutting at the expense of quality. The purchaser is to blame for the poor result as often as the supplier.

Reference has been made to a proper method for plating upon zinc. Every base metal requires a plating procedure adapted to it. The method which the writers consider best adapted to zinc either in the rolled or die cast form has been previously described.** This method is not inflexible but modifications of it demand a knowledge of the principles on which it is based. It is the purpose of this paper to describe these principles.

PREPARATION FOR PLATING

Practically all plated articles are brought to a high luster by grinding, buffing and coloring before plating. These operations may readily be accomplished on zinc. The only precautions to be observed are to avoid too high a wheel speed, 5000 to 6000 peripheral feet per minute is acceptable, and to use a dry coloring compound. The use of lime white should be avoided. The reasons for these requirements will become evident in the discussion of cleaning.

CLEANING, RINSING AND ACID DIPPING

Cleaning is a much more complicated task than is generally recognized. Every plater knows that good adhesion cannot be obtained over a greasy surface, but apparently it is not as clearly realized that grease removal is only half the problem of cleaning.

For cleaning some metals other than zinc, hot aqueous solutions of strong alkalies are effective and safe, but such materials react with zinc and other amphoteric metals to form ampholytes which are almost as conducive to poor adhesion as the grease film originally present. It is essential in the cleaning of zinc that the cleaner used be selected to give the least possible attack on the metal. A practical rule is that any cleaner which produces a strong tarnish film in less than two minutes should be avoided.

Since a minimum exposure to even a mild cleaner is desirable, the use of a dry coloring compound in the preparation of the article is of value. If excessive grease is present from some unavoidable cause, an organic solvent may be used prior to the usual cleaning.

The writers have found the following solution and method to give excellent results on zinc:

Tri-sodium phosphate—6 ounces per gallon. Use boiling hot as an electro-cleaner with sufficient current to cause copious gassing. $^1/_2$ to 2 minutes should be sufficient for complete cleaning.

Commercial cleaners designed for zinc are available. These should be used in accordance with the manufacturer's directions and with the above precaution against excessive tarnishing.

Following the cleaning, a *hot*, clear water rinse is recommended. As the article leaves the cleaner it holds an adhering film of hot solution, saturated with zinc salts and sodium stearate (or the sodium salt of other fatty acids which may be present in the grease binder of the buffing compound). Should the work be plunged into a cold water rinse, the lowered solubility of these compounds would permit deposition on the surface and in the contracting pores and crevices, which occur in the surface of practically all metals. A hot water rinse, on the other hand, will remove this film

* Metal Section, Research Division, New Jersey Zinc Company, Palmerton, Pa.

** Plating of Rolled Zinc and Zinc Base Die Castings—Research Bulletin—New Jersey Zinc Company, New York City.

Die cast radiator emblem bar plated with nickel and chromium.

and keep the pores open until the solution is washed out, thus minimizing the danger of poor adhesion from these sources. A cold rinse should follow to complete the washing and to bring the article to room temperature before the next step.

Soft water is highly desirable for the cleaning solution and for rinsing as the following considerations will show. A considerable proportion of the buffing compounds used on zinc employ a binder composed mainly of stearic acid. Under the action of the cleaner the stearic acid is saponified to sodium stearate which remains suspended in the cleaner. In the presence of soluble calcium salts, sodium stearate reacts to form an insoluble, adherent, calcium stearate which is extremely difficult to remove by rinsing. Thus the presence of calcium, either as a constituent of hard water or as lime white used in coloring, will unduly complicate the problem of cleaning.

The necessity for avoiding tarnish films caused by excessive action of alkalies, has been pointed out. Under favorable conditions, a correct cleaning procedure will often permit successful plating immediately following the rinse. More often, however, the use of an acid dip to remove any remaining alkaline film will be desirable. A $^1/_2$ to 2 minute dip in cold, 1% hydrofluoric acid or 10% hydrochloric acid will remove the adhering zinc salts and will give an additional guarantee of perfect adhesion. With a subsequent rinse in cold water to avoid carrying acid into the plating bath, the article is ready for plating.

Appearance of 0.00015 inch nickel coating after outdoor exposure. Note areas of corrosion.

It is possible that in the attempt to make clear the reasons for the various steps considered, the impression has been given that the process is unduly complicated and burden some. On the contrary, the actual procedure is extremely simple and no more complicated than for other metals. In fact the greater part of what has been said may be applied to the cleaning of other metals.

PRIMARY COATINGS

The writers believe that nickel is by far the most desirable primary coating to apply over zinc, regardless of the final coating to be applied.

There is an occasional advocate of a copper flash coating. The reason given usually is that the copper aids in throwing subsequently deposited nickel into recesses not otherwise coverable. This is not necessarily true. In a nickel solution properly adapted to zinc, the improvement in throwing power of the nickel obtained by the use of a copper flash may be very small. In any event the thickness of nickel deposited over a copper flash in a recess will be too thin to be of any value in protecting the base metal. Any article so complicated in shape as to be impossible to cover completely in a properly regulated nickel bath should be plated with auxiliary anodes. The designer should take into consideration the fact that deep recesses are difficult to cover with a coating of sufficient thickness for adequate protection.

Copper, brass, gold and silver tend to dissolve readily into zinc at room temperature and more rapidly at slightly elevated temperatures. For example, a coating of copper 0.0005 inch thick may be completely absorbed by the zinc base after only 10 days' exposure at 100° C. Therefore, if a copper finishing coat is required it must be protected from absorption by a primary nickel coat. If copper is used as a primary coating the adherence of subsequent coatings may be affected by its ultimate diffusion into the base metal.

All of the 4 metals mentioned above must be deposited from cyanide solutions for successful deposition directly on zinc. Cyanide solutions demand extreme care in order to avoid blistering. In those cases of blistering on nickel plated die castings that have come to our attention, the cause has usually been found to be a flash copper coating which has lifted away from the zinc.

None of these difficulties occur when nickel is properly applied as the primary coating directly on zinc. The few occurrences of blistering of nickel on zinc which have been brought to the writers' attention have been the result of insufficient or improper cleaning.

NICKEL PLATING

The durability of plated coatings is dependent largely on their thickness, a fact that is slowly being realized by users. Plated coatings on zinc die castings for outdoor exposures should be at least 0.0003-inch thick. In the past, and to a certain extent to-day, it is not uncommon to find deposits of nickel on zinc die castings as thin as 0.00005 inch.

Almost any kind of a solution can be used to put a very thin nickel coating on zinc, since the defects in some baths are not apparent until the deposit becomes heavy, but certain essentials discussed below must be respected if a good quality heavy coating is to be obtained at low cost.

When zinc (or any other metal above nickel in the electro-chemical series) is placed in an electrolyte containing nickel ions, the normal replacement phenomenon takes place with zinc going into solution and nickel depositing on the article. Normally, the resulting deposit is a non-adherent black coating which offers no great value either for protection or decoration.

It is necessary, in order to obtain bright electrodeposits, that a sufficiently high current density and a low enough nickel ion concentration be used to prevent this immersion deposition. In the earlier days of plating on zinc, baths of very low nickel content were common. These solutions functioned fairly well since the low metal content automatically provided a low ion concentration.

The objection to this type of bath lies in the fact that a large proportion of the nickel present is ionized. As the plating proceeds the nickel ions in the film adjacent to the cathode are depleted and, since the concentration of un-ionized nickel is too low to immediately replenish the nickel ions removed, polarization increases. Since the nickel present in the remainder of the solution exists largely as nickel ions, replenishment of the cathode film must take place by the slow process of ion migration or by means of convection currents. The net result is an extremely low ion concentration in the

cathode film and a very fine grained, hard, brittle nickel deposit.

A better plating solution would obviously be one with a high nickel content but with a low nickel ion concentration. This can readily be realized in 2 ways; the addition of sodium sulphate will depress the normal ionization of nickel sulphate by the common ion effect; and sodium citrate also acts to depress the ionization of nickel sulphate, although the mechanism by which it operates is not clearly understood.

The situation in the cathode film changes when a large quantity of undissociated nickel sulphate is available. As fast as nickel ions are deposited un-ionized nickel present in the film can become ionized. Convection currents caused by gas evolution tend to keep up the supply of nickel sulphate in the cathode film as well as to draw in fresh supplies of ions and hence prevent excessive polarization. The nickel coating produced in this manner can be carried to 0.0003 inch without trouble.

Commercial baths embodying both of the above principles of ionization depression have been in use for some time. The writers prefer the sodium sulphate bath on the basis of its better conductivity, throwing power and overall efficiency.

The following bath has been used with good success and is recommended for zinc and zinc alloys:

Single nickel salts—10 ounces per gallon
Anhydrous sodium sulphate*—10–15 ounces per gallon
Ammonium chloride—2–3 ounces per gallon
Boric acid—2 ounces per gallon

* If the hydrated salt is used, add double the amount.

Appearance of 0.0003 inch nickel deposit after same exposure. Note freedom from corrosion.

The sodium sulphate content should be regulated in accordance with the shape of the objects to be plated. Softest deposits are obtained with the minimum addition of this salt. The current density should be controlled between 12 and 18 amperes per square foot. If possible, a somewhat higher initial current should be used for 1 or 2 minutes in order to minimize the danger of streaking.

The bath is best operated at pH of 5.8 to 6.2 (colorimetric uncorrected).* Ammonium hydroxide or sulphuric acid should be used in making adjustments. The relation between anode and cathode areas should be controlled to minimize such adjustments. If the solution continuously becomes alkaline, the nickel content is increasing too rapidly and the anode area should be reduced. Conversely, an acid condition may be controlled by increasing the anode area.

It is customary to operate the sulphate bath at room temperature. It would, perhaps, be advisable to impose more definite limits, since most plants have no facilities for control of temperature in the hot months. Best results are obtained at 26° C. (79° F.) although successful plating is feasible between 24° and 30° C. (75° to 86° F.). Too low a temperature facilitates the formation of brittle deposits by unduly depressing ionization while warm solutions tend to cause streaks due to the reverse effect.

It will be noted from the formula that the nickel content of the bath, calculated as metal, is about 2 ounces per gallon. There should be no difficulty in holding closely to this amount. It is advisable, however, to check the nickel content at intervals. In this connection the writers have found no difficulty in using 99% nickel anodes with this bath.

* Corresponds to 5.3–5.7 by the quinhydrone electrometric method.

The two-ounce nickel, high-sulphate bath has a high cathode efficiency and permits the deposition of nickel at a fairly rapid rate. Table 1 shows the plating time necessary, at various current densities, to deposit 0.0003 inch of nickel.

Table 1.—Time in Minutes to Produce 0.0003 Inch of Nickel at Various Current Densities

Current Density amps./ft.^{2}	Time—Minutes
8	46
10	38
15	22
18	21
20	20
25	15
30	13
36	11
40	9.5

It will be seen that at its upper usable limit of current density (about 20 amps./ft.^{2}) this bath can deposit 0.0003 inch of nickel in 20 minutes. Frequently the demand on equipment is such that shorter periods must be employed. Since this requires the use of higher current densities to maintain a satisfactory standard of thickness, the two-ounce solution has been modified to permit operation up to 36 amperes per square foot. The improved solution is as follows:

Single nickel salts—15–18 ounces per gallon
Anhydrous sodium sulphate*—15 ounces per gallon
Ammonium chloride**—3 ounces per gallon
Boric acid—2 ounces per gallon

* If hydrated salt is used add double the amount.
** The simultaneous addition of nickel sulphate and ammonium chloride brings the solution nearer to the solubility limit of the nickel ammonium sulphate formed in the bath. For this reason any addition of ammonium chloride beyond 3 ounces per gallon should be made cautiously and pH adjustments should be made with sodium hydroxide or hydrochloric acid as required.

This solution is used at 24-30° C. with a colorimetric* pH range of 5.4-5.9. The plating range is 24-36 amperes per square foot. Inspection of Table 1 will show that at a maximum current density, 0.0003 inch of nickel can be applied in 11 minutes.

This bath has been found commercially practical and in appearance and quality the deposits are equal to the slower deposits from the two-ounce solution.

TESTS ON PLATED COATINGS

The necessity for adequate thickness of coating, and the imperfect recognition of this necessity have been mentioned. The percentage difference in cost between coatings which are too thin and those that are satisfactory is very small. Certainly the nickel and the current used represent a small proportion of the total cost of plating. Polishing and buffing, which have little or nothing to do with the plating operation itself, represent a much larger proportion of the costs. Yet small cost differences may govern if the quality difference is not understood.

From the plater's standpoint the competition of non-rusting white metals demands that he look to the

* Corresponds to 4.9–5.4 electrometric.

Die cast radiator cap successfully plated with nickel and chromium on a commercial scale. Note that the overhang of the wings imposes a severe requirement on throwing power.

quality of his work. There is a tendency to blindly assume that lack of complaints means a satisfactory product. This is not necessarily true because, in the first place, some time must elapse before even a poor plating job will fail. In the second place, the plated article frequently passes through several hands, in the processes of manufacture and distribution, before reaching the ultimate consumer. These circumstances unquestionably minimize the chances of a positive complaint coming back to the plater. There is nothing, however, to prevent a suspicion in the mind of the consumer that all plated ware may be unreliable if he happens to encounter one or two plated articles of unsatisfactory durability. This frame of mind makes the consumer receptive to competitive substitutes and thus reacts upon the entire plating industry.

A serious handicap to intelligent buying lies in the difficulty of finding suitable tests for the plated material. The failure of the well-known salt spray test to serve as a yardstick of service performance has been considered in detail elsewhere.* Other laboratory and plant tests have been suggested, all of which have the same fundamental defect as the salt spray test; namely, that they fail to predict correctly the service life of a series of materials.

The writers have become convinced, after several years of corrosion studies, that the best way to determine how long a given material will last in the outdoor atmosphere is to expose it to the outdoor atmosphere. They do not know of any accelerated test which can be trusted to forecast the true service life of plating.

The writers have conducted numerous continuous atmospheric exposure tests as well as service tests on plated zinc alloy die castings. The results confirm the statement that the minimum thickness of nickel which is satisfactory over zinc for outdoor service is 0.0003 inch. Thinner coatings are distinctly inferior and thicker coatings do not seem to be required to give the life which may reasonably be expected.

The Use of Aluminum for Oil Lease Tanks

The corrosive action of concentrated brines on aluminum tank plates under different operating conditions is described by the United States Bureau of Mines, Department of Commerce, in Report of Investigations 3131, "The Use of Aluminum for Oil Lease Tanks: Part II–Laboratory Tests." by Ludwig Schmidt, John M. Devine and C. J. Wilhelm.

In order to study corrosion conditions encountered in the tanks during the test period, a laboratory was maintained at the site of the aluminum lease tanks.

All metals have an inherent tendency to go into solution when in contact with water. The extent of this tendency varies for different metals, depending upon their position in the electromotive series. Investigators generally agree that aluminum owes its resistance to corrosion to the protective action of a superficial layer of oxide which is established in sites by autoxidation. Inasmuch as the metal itself is located relatively high in the electromotive series, it is evident that any set of conditions whereby the oxide film is ruptured or rendered pervious to aqueous solutions will result in rapid corrosion of the metal when in contact with such solutions.

The potential corrosive agents to which the aluminum tanks were subjected in service included natural gas, oil and salt water, each of which contained free hydrogen-sulphate gas in varying proportions. The field test proved that natural gas and oil were without corrosive effect on the tanks. The salt water, however, was capable of producing serious corrosion. Hydrogen sulphide, in dissolved or free state, did not have any direct action on the tanks, but indirectly it was a contributory factor to corrosion through the production of iron sulphide by interaction with the steel flow lines. Iron sulphide, so formed, was flushed into the tanks and functioned as an accelerator to salt-water corrosion.

All of the corrosion in the aluminum tanks was of highly localized nature, resulting in a pitting attack. Nevertheless, it was possible to identify three distinct types of corrosion:

(1) Low-temperature salt-water corrosion, which was encountered where aluminum side sheets of tanks were exposed to the action of salt water.

(2) High-temperature salt-water corrosion, which was encountered in the corrosion of aluminum steam-heating coils within the tanks.

(3) Bimetallic corrosion, which was caused or accelerated by the proximity of steel in electrical contact with aluminum; such corrosion resulted where steel steam-heating coils were installed in aluminum tanks.

SHERARDIZING

BY FRED L. WOLF*

PRIOR to 1910 and 1911, most of the electrical line materials, made of malleable iron for use in connection with street railways and mines, were protected against corrosion by means of paint, japan and the electrogalvanizing process. About this time the trade became more critical and demanded better rust proof castings to be supplied.

The Ohio Brass Company then installed a hot galvanizing plant, but considerable trouble was encountered due to malleable iron becoming brittle after hot dipping. It was also found impossible to hot dip threaded material satisfactorily.

About 1910 and the early part of 1911, the sherardizing process was brought to our attention. A small experimental unit was built, considerable development work was carried on, the results of which were quite satisfactory, and we succeeded in turning out a good rust proof coating on castings. Threaded material could easily be treated and the embrittlement effect which was encountered when treating malleable iron by means of hot galvanizing process was much less pronounced.

Early in 1911, a license was taken out, production furnaces were built and the sherardizing process was established as a standard method for rust proofing our castings.

Without going into a lengthy recital of experiences and details, it was found that it was necessary to do a large amount of research work to determine the proper

* Technical Superintendent and Chief Engineer, The Ohio Brass Company.

Hot dipped and sherardized castings exposed outdoors from March 1915 to October 1931. The hot-dipped specimens show some discoloration of the zinc, but no corrosion of the casting itself, while the sherardized castings are badly pitted.

metallic content of zinc dust used, the time involved, the temperatures, etc. During the periods 1911 and up to the time this company discontinued the sherardizing process (Dec. 1, 1923), weekly samples of castings treated by both the sherardizing and the hot dip galvanizing processes were exposed to the atmosphere for the purpose of observing what corrosion, if any, took place. There were probably several tons of castings exposed for this purpose, most of which are still available and on hand. Observations over a long period of time have shown that castings treated by the sherardizing process are very much inferior, when it comes to the question of withstanding corrosion over a long period of time, to those treated by the hot dip galvanizing process. Inspecting castings exposed since 1911, the author would say that at least 50 to 75% of those which were sherardized are very badly corroded while the castings hot dip galvanize treated and exposed at the same time show absolutely no failures.

A sherardized clamp casting, sherardized in an electric furnace with all factors under good control. The casting was never exposed to out-door corrosion, having been in a stock bin for about one year. It shows appreciable corrosion.

In the sherardizing process it was difficult to maintain an absolutely uniform condition so as to be sure that every casting had been brought in proper contact with the zinc dust, and to be sure that it was completely and sufficiently coated. Every precaution was taken to inspect and test each lot of castings as they came from the retorts, setting a minimum of 6 dips using the Preece test, and in spite of proper furnace design, pyrometric control and technical supervision, it was found impossible to maintain uniformity.

When it was discovered that the great problem of embrittlement could be eliminated by the proper treatment of malleable iron castings prior to hot dip galvanizing and also that by means of properly designed centrifugal machines threaded material could be hot dipped, the company at once discontinued the sherardizing process and treated all castings by means of hot dip galvanizing. The author believes a check up over a period of years will show that the sherardizing process has not been satisfactory and that very few concerns are still carrying on.

It is true that if all conditions are right an excellent rust proof coating can be obtained by sherardizing. If the casting is covered 100% properly its resistance to corrosion will be equal to any hot dip galvanized coating. The trouble lies in the fact that sherardized castings which have been tested under corrosive conditions as well as others which have been observed in service show that it is not possible to produce a 100% job.

It is also true from observations over a period of 20 years that in no case has the author observed a failure of a hot dip galvanized casting when exposed to normal atmospheric corrosion but sherardized castings exposed over a similar period showed at least 50 to 75% partial or total failures.

U. S. Mint Aids Prospectors

State Mineralogist, Walter W. Bradley, has been advised by Mr. M. J. Kelly, Superintendent of the Mint at San Francisco, that the Mint now accepts gold in quantities of 2 ounces and over.

The rules and regulations governing the U. S. Mints state that a deposit must be of $100 value before it can be received, but prior to 1926, deposits of $50 value were accepted at the San Francisco Mint. In 1926 orders came from Washington to adhere to the $100 rule, and this order has been enforced until this year, when on June 2nd, the Director of the Mint authorized the Superintendent at San Francisco to accept deposits of gold in quantities of 2 ounces or over. The order applies only to gold in the natural state, and not to dental or jewelry scrap, or other fabricated material.

This permission has been granted for the purpose of giving encouragement to small-scale placer mining during the present season only, and is not permanent.

Manganese Steel Welding Rod

The AMSCO Manganese Steel welding rod is a result of research work done at the Chicago Heights plant of the American Manganese Steel Company, commencing several years ago. The rod was developed to give a welding rod that would leave a deposit equivalent in analysis and physical properties to heat treated manganese steel; that could be used by any fairly competent welder with the electric arc with good results; and that would not require special heat treating or quenching, but would give the characteristics of standard manganese steel under ordinary air-cooling.

The AMSCO Manganese Steel rod can be used in the repair of manganese steel castings and the reclamation of such manganese steel equipment as dipper teeth, crusher mantles and jaws, railway track members, etc. It can be used for these purposes on parts of ordinary steel and also for a wear resistant coating on almost any kind of steel casting.

American Foundrymen's Association to Return to Philadelphia for 1932 Convention

The 36th Annual Convention and Exhibit of the American Foundrymen's Association will be held in Philadelphia, May 2 to 6 1932, according to an announcement made by the Association. The Convention and Exhibit activities will be centered in the new Municipal Convention Hall, located at 34th St. and Vintage Ave.

Tentative plans for the 1932 program include a number of practical shop-operation and round-table sessions of the type which proved so popular at the 1931 Chicago Convention that the meeting rooms there were taxed to capacity. The Philadelphia Convention Hall, however has broad facilities in the way of meeting rooms to fit any requirement of the annual foundry meeting.

Mechanism of Energizer Action in Carburization

BY R. A. RAGATZ* AND L. O. KOWALKE*

THE remarkable acceleration in the rate of carburization of steel produced by the addition of small quantities of certain alkali and alkaline earth carbonates to solid carbonaceous materials has long been recognized and utilized in the preparation of commercial case hardening compounds. When a pronounced catalytic effect such as this is discovered and gains extensive commercial application, efforts are naturally made to explain the mechanism of its action. One explanation of the rôle played by certain alkali and alkaline earth carbonates was proposed quite a number of years ago and gained wide acceptance if judged by the frequency of its statement in the technical literature. It is only within recent years that this widely accepted theory has been questioned by some. A few investigators who were dissatisfied with the older theory have proposed theories of their own, but these newer ones also are not in entire accordance with certain experimental data. The writers of this paper have performed a series of tests[1] on the energizing action of a great variety of compounds. On the basis of these results, together with certain theoretical considerations, the writers have developed a theory of energizer action which will be presented in this paper.

Before entering upon a discussion of the mechanism of energizer action, it will be desirable to discuss: 1. The mechanism of carburization with pure carbon. 2. The decomposition temperatures of carbonates in an atmosphere composed of carbon monoxide and carbon dioxide. Then a discussion of the previously proposed theories will be in order. Finally, the explanation of the writers will be offered.

MECHANISM OF CARBURIZATION

Most texts on the heat treatment of steel discuss carburization in a purely empirical manner, without making any attempt to clearly picture the kinetics of the process and without discussing the reactions involved from the standpoint of physico-chemical theory. The carburization of steel will be treated from the latter viewpoint, because it presents a clear-cut picture of the mechanics of carburization which is essential to an understanding of the discussion on the action of energizers. To simplify matters, it will be assumed that the carburizing agent is pure solid carbon, rather than a carbonaceous material that evolves large quantities of gas on heating.

The question of direct interaction between the solid carbon and the steel should first be considered. If a piece of steel is heated in contact with pure solid carbon in the total absence of all gases, can the carbon migrate directly into the steel? Controversy over this point engaged the attention of metallurgists for many years. The work of the various investigators has been reviewed in detail by Giolitti.[2] The present conclusion is that pure solid carbon, in the total absence of all gases, can act directly on steel, but it is an extremely slight action, and can be entirely neglected from a practical standpoint.

This conclusion applies to the carbonaceous material in which the steel was originally packed. A similar question might be asked with respect to the pure carbon precipitated on the steel in very finely divided form by the decomposition of certain gases such as carbon monoxide or hydrocarbons. As will be pointed out later, 2 investigators hold the belief that such finely divided carbon can readily be absorbed by the steel.

Now consider what takes place when steel is heated to a temperature in the vicinity of 1750° F. (955° C.) in a carburizing box packed with pure solid carbon. The air entrapped in the box will combine with carbon to form an atmosphere consisting of nitrogen, carbon monoxide and carbon dioxide. The carbon monoxide will react with the steel according to the following reaction:

$$3Fe + 2CO \longrightarrow Fe_3C + CO_2 \quad \ldots (1)$$

The cementite thus formed at the outer surface of the steel dissolves and diffuses inward. The carbon dioxide which is a by-product of the carburizing reaction is regenerated by the hot carbon, as indicated by the following reaction:

$$CO_2 + C \longrightarrow 2CO \quad \ldots\ldots\ldots (2)$$

The carbon monoxide then reacts with the steel, thereby carrying the process of carburization further. It is evident that the gases act in a cyclic manner and that the carbon monoxide acts as a carrier of carbon from the carbonaceous solid to the steel.

Fig. 1 illustrates in schematic form the conditions at some particular time during the carburizing process. The upper sketch indicates, on a highly magnified scale, a particle of carbon close to the surface of the steel, with an intervening gaseous phase that consists of nitrogen, carbon monoxide and carbon dioxide. At the surface of the carbon, a definite concentration of carbon monoxide as indicated by point A will be established, while at the surface of the steel another and somewhat lower concentration of carbon monoxide will be established as indicated by point C. The lower concentration of carbon monoxide at the steel surface with respect to its concentration at the carbon surface is due

* Chemical Engineering Department, University of Wisconsin.

to reaction (1). A gradient of carbon monoxide concentration is thus established which causes the carbon monoxide to diffuse from the carbon surface to the steel.

The conditions with respect to the carbon dioxide are just the reverse. At the steel surface its concentration is increased by reaction (1), while at the carbon surface its concentration is decreased as a result of reaction (2). In this way, a gradient of carbon dioxide is established that causes the carbon dioxide to diffuse from the steel surface to the carbon surface, countercurrent to the flow of carbon monoxide.

The flow of carbon monoxide and carbon dioxide between the two interfaces where the reactions are occurring is entirely a diffusional process, as convection currents may be assumed to be absent in the gaseous phase after the carburizing temperature is established. The flow of gas between the 2 surfaces therefore proceeds according to Fick's Law of diffusion:

$$\frac{dW}{dt} = -Dq\left[\frac{dc}{dx}\right] = \text{weight of material transferred per unit of time} \quad \ldots\ldots (3)$$

D = diffusion constant
q = area
$\frac{dc}{dx}$ = concentration gradient.

Any attempt to apply Fick's law in a quantitative way to the process of carburization is beset with many difficulties, as it requires a knowledge of the concentration gradient between carbon and steel. The concentration gradient is determined by: 1. The gas composition at the gas:carbon interface, 2. The gas composition at the gas:steel inferface, 3. The mean effective distance between the carbon particles and the steel.

The equilibrium gas compositions have been determined for the $C:CO_2:CO$ system[3,4,5,6] and for the steel:$CO:CO_2$ system.[7,8,9] However, these values do not necessarily give the gaseous compositions at the gas:carbon and the gas:steel interfaces, as it is always questionable whether the equilibrium values are assumed at the interfaces in a heterogeneous chemical reaction, particularly if one phase is a solid and the other a gas.[10,11] At the steel:gas interface an additional complication arises due to the constantly varying carbon content of the austenite, which demands constantly changing gas compositions for equilibrium.

Since the carburizing agent consists of a large number of carbon granules which are in actual contact with the steel at certain points, it is difficult to determine what shall be considered the mean effective distance between steel and carbon.

Though a quantitative application of Fick's Law to the carburizing process is difficult, some interesting qualitative deductions may be drawn. The rate of material transfer from carbon to steel is directly proportional to the concentration gradient $\left(\frac{dc}{dx}\right)$. If this gradient is increased either by increasing the concentration difference (dc) or by decreasing the effective distance (dx), the velocity of carburization will be increased. This point has a bearing on the proposed explanation of energizer action, as will be pointed out later.

In a discussion of the mechanics of carburization, consideration should be given to the manner in which the carbon migrates to the interior of the steel. Formerly the view was held that the gas actually diffused into the steel and that the carburizing reaction was not confined to the surface of the steel, but also took place in the interior regions. The researches of Takahashi[12] proved this to be incorrect. He demonstrated that the reaction is confined to the outer surface of the steel, and that the iron carbide formed there dissolves and migrates into the steel by a process of diffusion.

Fig. 2.

DECOMPOSITION OF CARBONATES

Discussion of the theories proposed to explain the action of carbonate energizers requires that certain points regarding the decomposition of carbonates be clearly understood.

When a carbonate is heated in the absence of carbon, it tends to dissociate into metallic oxide and carbon dioxide as indicated by the following general equation:

$$MCO_3 \rightleftarrows MO + CO_2 \quad \ldots\ldots (4)$$

At each specific temperature the carbonate will tend to establish a definite pressure of carbon dioxide. The decomposition of the carbonate according to the above equation will be determined by the relation between the pressure of carbon dioxide the carbonate tends to establish, and the partial pressure of carbon dioxide existing in the gaseous phase in contact with the carbonate. If the carbon dioxide pressure in the gaseous phase is less than that of the carbonate, decomposition of the carbonate will occur according to reaction (4). Conversely, if the carbon dioxide pressure in the gaseous phase is greater than that of the carbonate, any metallic oxide which is present will revert to carbonate.

The velocity at which a carbonate will decompose or the velocity at which it is re-formed from metallic oxide and carbon dioxide will be determined by: (1) The differential between the carbon dioxide pressure of the carbonate and the partial pressure of carbon dioxide in the gaseous phase. (2) The velocity of the gas, if it is circulated around the particles of carbonate. Furthermore, when the carbon dioxide pressure of the carbonate equals the total pressure of the gaseous

phase, decomposition will be very rapid, as the carbonate in effect "boils."

How will carbon, when present in considerable amount, affect the direct decomposition of carbonate according to equation (4)? It is well known that at constant pressure, the $C:CO:CO_2$ system tends to establish a definite composition of gas at each specific temperature. The composition of the gaseous phase will be altered by dilution with atmospheric nitrogen, but may readily be computed if the equilibrium gas composition with no nitrogen dilution is known. The possibility of a carbonate decomposing directly, according to equation (4), will be determined by the relation of its carbon dioxide pressure to the partial pressure of carbon dioxide in the gaseous phase, as established by the $C:CO_2:CO$ equilibrium.

Reference to Fig. 2 will help in this discussion. This graph shows the relation between the pressure of carbon dioxide and the temperature, for the following reactions: (1) $Na_2CO_3 \rightleftarrows Na_2O + CO_2$, (2) $C + CO_2 \rightleftarrows 2CO$ when no diluting nitrogen is present and the total pressure is 1 atmosphere, (3) $C + CO_2 \rightleftarrows 2CO$ when the gases are diluted with atmospheric nitrogen, and the total pressure is 1 atmosphere. The intersection of curves 1 and 2 gives the minimum temperature (1756° F., 958° C.) at which sodium carbonate can decompose directly, according to equation (4), when no diluting nitrogen is present. Dilution with atmospheric nitrogen lowers the minimum temperature of direct decomposition to 1585° F. (863° C.), as indicated by the intersection of curves 1 and 3.

In Table 1 are given the minimum temperatures of direct decomposition for various carbonates, determined as indicated above.[13] The limitations of these figures should be clearly understood. They only represent the minimum temperatures at which various carbonates can decompose *directly*, according to equation (4). In some instances, it is possible that direct interaction between carbon and carbonate takes place. Decomposition of the carbonate under these conditions may possibly occur at lower temperatures than those indicated in Table 1. However, the data given in Table 1 are of value as they have an important bearing upon some of the theories that have been proposed to explain the action of energizers.

Table 1.—Minimum Temperatures of Direct Decomposition of Various Carbonates in the Presence of Carbon at One Atmosphere Pressure.

Carbonate	Decomposition Temperature: Gaseous Phase $CO + CO_2$		Decomposition Temperature: Gaseous Phase $CO + CO_2$ Diluted with Atmospheric Nitrogen

$BaCO_3$ Second step††	1909	1043	1805	985

* and ** Decomposition pressures for Li_2CO_3 as determined by Johnston and Lebeau are not in good agreement.
† $2\ BaCO_3 \quad BaO{\cdot}BaCO_3 + CO_2$.
†† $BaO{\cdot}BaCO_3 \rightleftarrows 2\ BaO + CO_2$.

Some reference works on inorganic chemistry state that certain carbonates, such as barium carbonate for example, can react directly with solid carbon according to the following reaction.[14,15]

$$MCO_3 + C \longrightarrow MO + 2\ CO \qquad (5)$$

The idea that such direct interaction occurs in some instances appears to be based upon the well known fact that the calcination of barium carbonate in commercial practice is greatly accelerated by the addition of carbon. Though no detailed research appears to have been carried out on reactions of this type, some experimental data afford indirect evidence that reactions of such type do occur and that they take place at lower temperatures than the minimum temperatures of direct decomposition listed in Table 1. Rapatz[16] investigated the decarburization of high carbon tool steel in various packing materials and found that the addition of sodium or barium carbonate to charcoal reduced or completely inhibited decarburization at those temperatures at which charcoal alone exerted a decided decarburizing effect. This appears to indicate that the presence of the sodium or barium carbonate creates a gaseous atmosphere higher in carbon monoxide than is normal for the $C:CO_2:CO$ equilibrium. This would result if the carbon and carbonate reacted directly to form carbon monoxide. Fox and White[17] present data showing that at 1470° F. (800° C.) (a decidedly lower temperature than that given in Table 1 for sodium carbonate) the addition of sodium carbonate to carbon gives a gaseous atmosphere of higher carbon monoxide content than is normal for the $C:CO_2:CO$ equilibrium. This again indicates direct interaction of carbonate with carbon, resulting in the production of carbon monoxide. In view of this indirect evidence and the lack of data to the contrary, we have concluded that direct interaction of carbon with carbonate can occur at temperatures below the minimum temperatures of direct decomposition as given in Table 1.

Fig. 3. Cyclic Reactions Proposed by Fetchenko-Tschopiwskij.

In the case of sodium and potassium, the metallic oxide formed by reaction (5) will react further with the carbon to form carbon monoxide and sodium vapor, as indicated by the following reaction.[18]

$$Na_2O + C \longrightarrow CO + 2Na \qquad (6)$$

The oxides of lithium, barium, strontium and calcium will not react similarly.

In Table 2 are listed the pressures of carbon dioxide that certain carbonates exert at a temperature of 1750° F. (954° C.).[13] This table is of particular interest as it shows clearly which of the metallic oxides act as efficient scavengers for carbon dioxide. For example, at 1750° F. (954° C.), sodium oxide will combine with carbon dioxide if the partial pressure of carbon dioxide in the gaseous phase is above 9.5 mm. However, calcium oxide at the same temperature can absorb carbon dioxide only if the partial pressure of carbon dioxide in the gaseous phase is 1690 mm. or over. Since carburization is always carried out at atmospheric pressure, it is apparent that calcium oxide at 1750° F. will be ineffective as a scavenger for carbon dioxide.

Table 2.—Decomposition Pressures of Various Carbonates at 1750° F. (954° C.)

Carbonate	Pressure of Carbon Dioxide, mm. of Mercury
Li_2CO_3 Johnston	64
Li_2CO_3 Lebeau	75
Na_2CO_3	9.5
K_2CO_3	6.1
$MgCO_3$	See note
$CaCO_3$	1690
$SrCO_3$	16
$BaCO_3$ First step	1.0
$BaCO_3$ Second step	0.3
$C:CO_2:CO$ No dilution	10.5
$C:CO_2:CO$ Diluted with atmospheric nitrogen	1.3

NOTE: Decomposition pressure of $MgCO_3$ not known at 1750° F. At 1292° F. (700° C.) the value is 359,800 mm.

PREVIOUS THEORIES

1. The Simple Carbon Dioxide Evolution Theory. One explanation of energizer action has appeared frequently in the technical literature.[19,20,21,22,23,24] According to this explanation, the carbonate dissociates into metallic oxide and carbon dioxide at the carburizing temperature. The carbon dioxide thus formed reacts immediately with the incandescent carbon to form carbon monoxide, to which is attributed the increased rate of carburization. Accordingly, then, the carburizing efficiency of a compound would be determined by its carbon dioxide content rather than by the metallic part of the compound.

The inadequacy of this simple explanation was first pointed out by Rodman,[25] who worked with a variety of carbonates of the alkaline earth and alkali metals. He reported that there was no relationship between energizing power and the quantity of carbon dioxide available in the various carburizing agents tested.

That the simple carbon dioxide evolution theory is untenable was also shown by an extensive series of tests by the writers.[1] It was shown that sodium carbonate, bicarbonate, hydroxide, acetate, oxalate, cyanide, chromate and tungstate all were approximately equally effective, when the carburizing agents were so proportioned that they had the same weight ratio between charcoal and sodium. Potassium carbonate, bicarbonate, hydroxide, acetate, oxalate, tetraoxalate, cyanide, ferrocyanide, ferricyanide, chromate, dichromate and permanganate were approximately equal in their effects as energizers. Barium carbonate, oxide, hydroxide, acetate and nitrate were also of equal effectiveness. These results indicated that the energizing effect was primarily determined by the metallic part of the compound, rather than by combined carbon dioxide. Furthermore, certain easily decomposable carbonates such as calcium carbonate and magnesium carbonate were found to be entirely inert as energizers.

2. The Cyanide Theory. When nitrogen comes into contact with a hot mixture of carbon, iron and sodium, potassium or barium carbonate, cyanides are formed. This reaction is the basis of the Bucher process for fixing atmospheric nitrogen. Since cyanides are powerful carburizers, some investigators concluded that the energizing power of sodium and barium carbonate was due to the action of cyanides formed from the atmospheric nitrogen entrapped in the retort. However, as reported by Giolitti,[2] it was proven that no trace of cyanides could be detected in the gases evolved from the carburizing retort, or in the used carburizing compound. The cyanide theory has definitely been abandoned.

3. The Cyclic Reactions of Fetchenko-Tschopiwskij. In Fig. 3 is a reproduction of the reactions proposed by Fetchenko-Tschopiwskij[26] to explain the energizing effect of barium carbonate and potassium carbonate. The important thing to note is the cyclic character of the reactions in which the energizer participates. Although his proposal represents a marked advance, the actual kinetics of the process are not adequately presented. Furthermore, though the formation of potassium vapor is indicated, it is regarded as playing no part in the energizing effect.

4. Takahashi's Theory. The following theory has been proposed by Takahashi.[27]

1. At the carburizing temperature, the carbonate starts to dissociate according to the reaction $MCO_3 \longrightarrow MO + CO_2$.
2. The carbon, which is the predominating component of the carburizing agent tends to establish the equilibrium gas composition demanded by the reaction $C + CO_2 \rightleftarrows 2CO$.
3. The carbon monoxide in the gaseous phase reacts with the metallic oxide liberated in step 1, according to the reaction $MO + 2CO \longrightarrow MCO_3 + C$.
4. The carbon precipitated in step 3 is in finely divided form and reacts directly with the steel.

According to Takahashi, the carbonate undergoes repeated dissociation and regeneration with an accompanying production of a large amount of finely divided carbon which is available for absorption by the steel.

A complete discussion of Takahashi's paper is prohibitive, but 2 objections to his theory may be mentioned. (1) One of the essential features in the proposed theory is a partial *direct* decomposition of the carbonate. Table 1 gives the minimum temperatures at which various carbonates can undergo direct decomposition in the presence of carbon. Yet it is known that materials such as sodium carbonate and barium carbonate are very active energizers at temperatures below those indicated in Table 1. (2) The theory proposed does not explain in a satisfactory manner the ineffectiveness of calcium carbonate. It is known that calcium carbonate will dissociate directly at carburizing temperatures. Takahashi presents data showing that when carbon monoxide is passed over calcium carbonate, a dense deposit of carbon is produced. Hence, according to his theory, calcium carbonate should act as an energizer, yet it is inert.

THEORY PROPOSED BY THE AUTHORS

Some specific cases of catalysis may be explained by the formation of an intermediate unstable compound which acts as a carrier between the reactants. Thus, it might be proposed that the energizing action of certain carbonates is due to the formation of carbides which act as carriers of carbon. However, there are objections to accepting such a theory. (1) The carbides in question are formed only with difficulty and at temperatures far above those employed in the carburization of steel. (2) Barium carbide is a very weak energizer as compared to barium carbonate.[1] The theory of the formation of intermediate carbides was therefore abandoned as untenable.

In discussing the mechanism of carburization, it was pointed out that one of the essentials of the carburizing process involved the regeneration of carbon dioxide according to equation (2). The reaction between carbon dioxide and carbon is known to be rather slow, and it is known that certain materials have a decided catalytic effect upon the reaction. In reviewing the literature on catalysts for the $C:CO_2:CO$ reaction, it was noted that there was a parallelism between the compounds that were effective catalysts for the $C:CO_2:CO$ reaction and those that were effective energizers in the carburization of steel.

Boudouard[28] found that finely divided iron, nickel and cobalt produced by the reduction of the corresponding nitrates were effective in accelerating the $C:CO_2:CO$ reaction. The writers[1] have found that oxides and carbonates of these metals (which will be reduced to the metallic state at the carburizing temperature) exert a definite energizing effect in the carburization of steel. Taylor and Neville[29] found that the $C:CO_2:CO$ reaction was catalyzed by sodium carbonate, potassium carbonate and nickel, but that ferric oxide, calcium carbonate and sodium chloride were ineffective. The parallelism is not exact here, as the authors found that ferric oxide and sodium chloride had distinct energizing effects. However, Taylor and Neville worked at a maximum temperature of 1058° F. (570° C.) which is considerably below tempera-

tures used in carburization. Fox and White[17] found the accelerating effect of sodium carbonate on the $C:CO_2:CO$ reaction to be very pronounced. It is well known that sodium carbonate is a very active energizer.

We propose that *the energizing action exerted by certain chemicals in the carburization of steel is primarily due to the catalytic effect produced upon the $C:CO_2:CO$ reaction.* This proposal will be developed in some detail, considering sodium, potassium, barium, strontium, calcium and magnesium carbonates and various other compounds.

1. Sodium and Potassium Carbonates. The following discussion is largely based upon the work of Fox and White[17] on the mechanism of the catalytic effect by sodium carbonate on the $C:CO_2:CO$ reaction.

At the surface of the carbon, the following reactions occur.

$$Na_2CO_3 + C \longrightarrow Na_2O + 2CO \quad (7)$$
$$Na_2O + C \longrightarrow 2Na + CO \quad (8)$$

The available data indicate that the sodium is evolved with considerable pressure, hence the products of the reaction at the carbon:gas surface are projected outward into the gaseous phase.

The carbon dioxide formed at the steel:gas interface by the reaction of the carbon monoxide with the steel combines with the sodium according to the following reaction

$$2Na + CO_2 \longrightarrow Na_2O + CO \quad (9)$$

If the partial pressure of carbon dioxide in the particular region where a sodium oxide molecule is formed is higher than the carbon dioxide pressure of sodium carbonate, further absorption of carbon dioxide from the gaseous phase will occur, thus:

$$Na_2O + CO_2 \longrightarrow Na_2CO_3 \quad (10)$$

Fig. 4. Schematic Sketch to Illustrate Energizing Effect of Sodium or Potassium Carbonate.

The sodium oxide and sodium carbonate formed according to equations (9) and (10) condense and fall upon the carbon surfaces. The cycle described is repeated many times.

The effect that these reactions would have upon the concentration gradients in the gaseous phase are depicted in a qualitative way in Fig. 4. The lower curve (A-C) illustrates the carbon monoxide gradient in the gaseous phase between a carbon particle and the steel surface, when no energizer is present. The upper curve (A'-C) illustrates the conditions when sodium or potassium carbonate is present with the carbon.

The sodium formed as vapor at the carbon:gas interface and projected out into the gaseous phase acts as a highly efficient scavenger for carbon dioxide. The carbon monoxide concentration at the carbon:gas interface is increased due to reactions (7) and (8). The net result is that a high carbon monoxide concentration is established in the main mass of the gaseous phase, and there will be a sharp drop in carbon monoxide concentration in a film of gas adjacent to the steel. This extremely high concentration gradient will result in a greatly accelerated rate of carbon monoxide transfer to the steel surface, and hence carburization will be speeded up.

2. Barium and Strontium Carbonates. At the point of contact with the carbon, the following reaction occurs

$$BaCO_3 + C \longrightarrow BaO + 2\,CO \quad (11)$$

Unlike sodium or potassium oxides, the barium oxide will not be reduced to the metallic state at the temperatures used in carburizing. The direct interaction of carbon and the carbonate will tend to increase the carbon monoxide concentration in the main mass of the gaseous phase beyond that demanded by the $C:CO_2:CO$ equilibrium.

In contrast with sodium and potassium carbonates, there is no metallic vapor evolved from barium or strontium carbonate, which when introduced into the gaseous phase acts as a scavenger for carbon dioxide. However, as Table 2 shows, the partial pressure of carbon dioxide in equilibrium with barium oxide is very low. Hence, the absorption of carbon dioxide from the gaseous phase will be more rapid than if the carbon dioxide were required to combine with the carbon. The net result of these effects is toward the establishment of the conditions depicted by the upper curve of Fig. 4.

3. Calcium and Magnesium Carbonates. The inactivity of calcium and magnesium carbonates is readily explained. Above 1335° F. (724° C.), calcium carbonate exerts a carbon dioxide pressure greater than that demanded by the $C:CO_2:CO$ equilibrium. Therefore, calcium carbonate will decompose directly in the presence of carbon at temperatures ordinarily used in carburization. The carbon dioxide pressure of calcium carbonate is very high (1690 mm. at 1750° F.), hence decomposition is rapid, and probably is complete by the time the carburizing temperature is reached. The carbon surfaces are coated with calcium oxide, but the latter cannot react with carbon to form carbon monoxide. Furthermore, the calcium oxide cannot absorb carbon dioxide from the gaseous phase due to the extremely high decomposition pressure of calcium carbonate. Therefore, the cyclic reactions described for sodium, potassium, barium and strontium carbonates cannot take place, and as a result, calcium carbonate is ineffective as an energizing agent. Magnesium carbonate is inactive for the same reasons.

4. Other Sodium Compounds. The authors[1] have shown that sodium carbonate, bicarbonate, hydroxide, acetate, oxalate, cyanide, chromate and tungstate are approximately equal in effect as energizers at 1750° F. (954° C.), when the carburizing agents are all so proportioned that there is the same ratio between the weight of charcoal and the weight of sodium. This result supports our proposed theory, when consideration is given to the changes that occur in the various compounds on heating in the presence of carbon. Sodium bicarbonate on being heated is decomposed into sodium carbonate, carbon dioxide and water, and hence, should be the equivalent of sodium carbonate. When sodium hydroxide is heated, water is driven off and sodium carbonate and sodium oxide will be formed. Organic compounds such as acetates, oxalates, etc., will yield sodium oxide, sodium carbonate and various gases. The gases evolved by the destruction of the organic radical do not appear to have an appreciable effect supplementary to that exerted by the sodium oxide and carbonate formed. Sodium cyanide likewise forms sodium oxide and carbonate, and at the same time cyanogen is evolved. This gas does not appear to intensify the energizing action of the liberated sodium oxide and carbonate. When sodium tungstate and chromate are heated, all of the sodium

appears to be converted into oxide and carbonate, as the energizing effect is approximately equivalent to sodium carbonate; the tungsten and chromium components of the respective compounds appear to be inert.

Other compounds of sodium, such as the chloride, the phosphate, the borate, etc., show reduced activities as compared with the carbonate. It appears that for these compounds the negative radical exerts an inhibiting effect, probably by preventing the conversion of all of the sodium into oxide and carbonate. In some instances, as with sodium sulphate, stannate and bismuthate, the lowered activity is due primarily to attack of the steel or deposition of reduced metal on the steel.

5. Other Potassium Compounds. Potassium carbonate, bicarbonate, hydroxide, acetate, oxalate, tetroxalate, cyanide, ferricyanide, ferrocyanide, chromate, dichromate and permanganate are all approximately equal in energizing effect at 1750° F. (954° C.), when the carburizing mixes are proportioned to have the same ratio by weight between charcoal and potassium. This equivalence gives further support to our theory. Compounds other than those mentioned show reduced activity, but many of them still exert a marked effect.

6. Other Barium Compounds. Barium carbonate, oxide, hydroxide, acetate and nitrate all yield approximately the same result at 1750° F. (954° C.) when the carburizing agents are so proportioned that a definite ratio by weight exists between the charcoal and barium. This is further evidence in support of the proposed theory. Compounds other than those mentioned show reduced activity. In these instances, it appears that some barium oxide is formed, but the negative radical prevents the complete conversion of barium to oxide and hence exerts an inhibiting effect.

7. Other Calcium and Magnesium Compounds. A variety of calcium and magnesium compounds are inert as energizers. In view of the explanation offered for the ineffectiveness of calcium and magnesium carbonates, this result is what would be predicted.

8. Compounds Other Than Those of the Alkali and Alkaline Earth Metals. Ferric oxide, ferrous carbonate, nickel oxide, basic nickel carbonate, cobalt oxide, cobalt carbonate, cobalt nitrate, tungstic acid, molybdic acid and ammonium molybdate exert distinct energizing effects.

It might appear that the positive results obtained with ferrous carbonate, basic nickel carbonate and cobalt carbonate are not in accordance with the proposed theory. These carbonates decompose very easily and the metallic oxide is reduced to metal. Thus the cyclic reactions taking place with sodium, potassium and barium compounds do not take place with iron, nickel and cobalt carbonates. However, it must be remembered that the explanations offered for sodium, potassium and barium carbonate are but special cases of the general theory proposed, namely, that *any substance capable of acting as a catalyst for the $C:CO_2:CO$ reaction will act as an energizer in the carburization of steel.* Boudouard[28] has shown that reduced iron, nickel and cobalt act as catalysts for the $C:CO_2:CO$ reaction, hence it is to be expected that any compound of iron, nickel or cobalt which will be reduced to the metallic state under the conditions of carburization, will act as an energizer. While in the cases of sodium, potassium and barium carbonates it is possible to describe quite satisfactorily the *way* in which the $C:CO_2:CO$ reaction is accelerated and hence carburization speeded up, it is not possible to do so for reduced iron, nickel or cobalt.

No data are available on the effect of tungsten and molybdenum compounds on the $C:CO_2:CO$ reaction, but in view of the fact that they exert an energizing action in carburization, it might be predicted that they will catalyse the $C:CO_2:CO$ reaction.

View of Proposed Hall of Metallurgy in the Museum of Science and Industry, Chicago.

A metallurgical extension class, the first of its kind to be organized by the Mineral Industries Extension Division of Pennsylvania State College, was formed last week at the Altoona shops, Pennsylvania Railroad. The class is composed of 25 men, consisting of chemists and engineers of tests.

The work to be covered will consist of the metallurgy and metallography of ferrous and non-ferrous alloys and bearing materials. Considerable stress will be laid on the examination of failures in track and equipment materials. Dr. D. F. McFarland, Prof. O. A. Knight and Prof. O. B. Mallin will teach the several subjects.

A Photographic Creep Testing Apparatus

BY D. A. ROBERTS* AND R. L. DOWDELL**

DURING the past few years various types of apparatus have been developed for determining the flow or creep of metals at elevated temperatures. The general procedure in a creep test consists in the loading of a specimen to produce a desired stress, usually the heating of the specimen at a constant temperature, and reading the resulting flow at desired intervals of time.

The design of various creep testing equipment varies widely in detail, but the basic principles involved in the heating and loading of the specimens are all quite similar. In general, the furnace, with its specimen holders, is mounted in a suitable steel frame, and the load applied through the specimen holders by means of dead weights acting through a lever system, or in the case of small loads by direct loading. The use of knife edges on the lever arms appears to be the most common practice, and in the case of apparatus employing very sensitive flow measuring devices, spring mounting for the frame to absorb vibration is employed.

The furnaces used for this type of work are of the resistance wire type. The windings are spaced so as to produce as uniform a temperature over the entire specimen as possible. End windings, uniform windings with auxiliary coils, and irregular spaced winding with most of the wire at the ends of the furnace are the general types in use. Furnaces of relatively small diameter and with a rather large ratio of length to diameter are preferred by most investigators. An individual controller for each furnace is frequently used, and the temperature automatically recorded within close limits.

The flow or creep measuring devices fall into three general classes: those using extensometers similar to the type used in ordinary tensile testing work; those in which the elongation is measured externally by means of dials operated by the movements of the loading lever arms; and those employing microscopes mounted on micrometer slides which sight through the furnace on to the gage marks of the specimen.

The creep test apparatus constructed at the University of Minnesota differs from other creep test apparatus in that a photographic method is used for determining the flow of the test specimen shown in Fig. 1. Briefly, this method consists in photographing the gap formed between a platinum wire and a platinum strip attached to a wire, the wires being located 2 inches apart on the gage length of the test bar. As the bar elongates the width of the gap, as shown in Fig. 2A, increases and photographs taken at desired intervals of time (Fig. 2B) show a record of the flow. The resulting photographic plates (lantern slides—negatives) projected through a lantern on to a screen produce any degree of magnification of the object or gap that is desired. The determination of the magnification was originally made by photographing a stage micrometer in exactly the same position as that occupied by the specimen (Fig. 3), and projecting the resulting plate in the same manner as mentioned previously. In future work, however, a "graduating engine" will be used to mill lines spaced accurately on the metal strip so that it will replace the stage micrometer. Each photographic plate will then indicate the exact magnification and so will be largely independent of the rest. This modified method will also be more accurate because the distance between the specimen and lens can undergo a slight variation without affecting the accuracy of the elongation measurements.

* Graduate Student. This paper was condensed from a thesis "An Apparatus for Determination of the Flow of Metals at Elevated Temperatures" submitted to the University of Minnesota in partial fulfillment of the requirements for the degree of Master of Science, in Metallography, Minneapolis, Minnesota, June 1931.

** Professor of Metallography, University of Minnesota.

General Form of Apparatus. The general assembly of the creep apparatus is shown in Fig. 4. It contains four test units and is built of steel angle and channel sections of welded construction to ensure the utmost rigidity. The design of the frame is such that the deflections resulting from loading are exceptionally small. The specimen holders are of stainless steel rods of 1 inch diameter having the following composition: 18% Ni, 8% Cr and 4% W. This material was selected because it does not scale at the temperatures used, has a high tensile strength at elevated temperatures and has about one-third the thermal conductivity of ordinary steel. Steel balls, seated between the frame and upper holder connection, aid materially in axially loading of the test bars. Steel yokes provided with pins connect the lower specimen holders to the lever arms (Fig. 4). The length of the upper holders is sufficient to allow the furnaces to be raised high enough to expose the entire specimen for any necessary adjustments.

The stress is applied to the specimens through lever arms of 5 to 1 ratio by the reaction of dead weights on bail boards. The levers are assembled by means of pin connected joints and can be leveled by means of the threaded eyebolts. A calibration of the pin connected joints used in place of the customary knife edges at high loads showed a friction loss of less than 0.20%. For small stresses the lower specimen holder can be loaded directly thus eliminating all error which might result from the lever system.

The lever arms were calibrated by placing known weights on the bail boards and weighing the reaction produced at the specimen holder with (Howe) platform scales weighing directly to 0.01 lb. The weight at the specimen holder was then compared with the product of the weight on the bail board and the lever ratio. Any difference in the two would be considered as the friction loss. The following tabulation from some of the figures from one of the units shows how the frictional loss is determined.

Weight on Bail Board × Lever Ratio Lbs.	Weight on Specimen Holder Lbs.	Difference Lb.
100.8	100.68	0.12
350.23	350.08	0.15
599.20	598.05	1.15

The load produced by the reaction of the weight of the lever arm was found to be 32 pounds for each unit because the bail boards and levers were all adjusted so as to be of the same weight.

Furnace. A cross section of the furnace used as shown is Fig. 5. The furnace is built around an alundum core of $1^1/_4$ inches inside diameter, 12 inches in length, and provided with helical grooves for the spacing of the windings. The windings are divided into two parts, each consisting of 25 feet of 16-gage nichrome wire. The windings are symmetrically spaced with respect to the test bar. Granular zirkite, held in place by asbestos paper and alundum cement, is used to surround the heating coils. This material is highly refractory and does not react with the furnace winding thus insuring long furnace life. The ends of the furnace are made of $^1/_2$-inch "transite" discs and the furnace shell is made of sheet iron. The remaining space in the furnace is packed with sil-o-cel. A steel collar provided with a set screw is attached to the upper transite disc and serves as a means of fastening the furnace to the upper specimen holder. A window for observing the elongation or creep of the specimen is cut into the furnace at a point opposite the lower end of the test bar. This opening is rectangular in shape and its height increases as it extends to the outside to allow the admission of light for illumination of the test bar.

Fig. 4. Photograph of 4-unit Creep Apparatus.

The furnace is automatically controlled by a Wilson-Maeulen controller, the control thermocouple being located in direct contact with the furnace winding. The temperature of the test piece is recorded by means of a Bristol recorder. In this case the thermocouple is attached directly to the shoulder of the test bar, by simply wiring on the hot junction after flattening the bead so as to allow it to conform with the contour of the specimen. Hoskins Chromel-Alumel couples of No. 22 gage (bare) were used in connection with a Leeds-Northrup Potentiometer Indicator for checking the actual temperature of the furnaces and regulating the setting of the controller. While the manual checks for temperature were not being made the Bristol recorder was in service and was used primarily to show the general weave of temperatures. Usually each pair of furnaces is operated by a separate controller with the aid of an outside rheostat.

An exploration of the temperature variation over the specimen showed that the ends of the specimen run at the same temperature and that the center is slightly colder. The temperature difference between the center and ends increases as the operating temperature is raised. Control with a variation of not over 5° F. at 800° F. and 10° F. at 1400° F. can be maintained. Such results could be expected from a furnace of this design as no heat is supplied at the center of the furnace because of the necessary window and the heat losses increase as the operating temperatures increase.

Flow Measurement. The test bar has a platinum wire and platinum strip attached to it in a manner similar to

Fig. 5. Diagrammatic sketch of furnace and camera.

that developed by Spring and Kanter[1] (Fig. 2). It was found that a thin strip with a square end along with a fine wire gave the best results. The strips used were 0.006″ thick, $^3/_{16}$″ wide, and were bent to fit the contour of the test bar. A bent strip possesses stiffness and resists any tendency to curl or distort. The wire used was 0.018″ in diameter. As platinum has a low coefficient of expansion, the wires hold their places as the test bar is heated. A slight scaling of the bar also tends to hold the gage wires in place.

Camera. The camera used for this work is a Bausch & Lomb equipped with a 72 mm. micro-tessar lens. The camera is mounted in a frame which allows the lens and plate holder to be adjusted separately. The camera frame slides on a track so that it may be moved to the various furnaces.

Illumination of the test specimen is provided by means of a 5 ampere carbon arc mounted in a suitable holder above the camera lens. Light from the arc enters the furnace through the window previously described (Fig. 5).

Determination of Creep. Photographs are usually taken of the gap between the platinum wire and platinum strip at various intervals of time. The usual magnification is four diameters. Lantern slide plates made by Eastman were used, mostly with an aperture setting of 16 and a time of exposure of about 45 seconds. These negatives are then projected in any projection lantern and usually magnified to 100 diameters. At this magnification the 0.10 mm. divisions on the stage micrometer appear 1 cm. apart on the screen. As it is possible to read the projected image to the nearest millimeter, direct readings of 0.01 mm. or 0.00039″ are obtained.

Sufficient work has been done with this equipment to indicate strongly that it has merit. In the early work, however, there was difficulty in maintaining the camera in constant focus throughout the long time test, but this difficulty will be eliminated in future work.

Main Features of Apparatus:

1. The flow readings are taken directly on the gage length of the specimen and are independent of any deflections that may occur in other parts of the apparatus.
2. The measuring apparatus is not subjected to the heat inside the furnace.
3. A permanent record of the flow independent of personal error in the results.
4. Capable of greater accuracy on measurements of elongation.
5. Records any change which specimen and indicating strip and wire might undergo during the long time tension test.

The writers are grateful to Mr. John L. Cox of the Midvale Company for the generous contribution of the stainless steel grips and also to Mr. Wm. Kahlbaum, formerly Research Associate at the Bureau of Standards, for his suggestion of a possible creep apparatus involving a photographic principle.

Continuous Strip Annealing Process and Fundamentals of Heat Transfer in Continuous Strip Furnaces*

BY O. JUNKER

Strip metals, especially brass and copper strip, are used in automatic or semi-automatic machines for making drawn metallic articles. This demands a strip having a uniformity of the highest deep drawing quality and smoothness of surface in the finished article, which is no longer possible to obtain by ordinary annealing methods.

Difficulties in Uniformly Annealing

Annealing closed strip in tightly wound coils of large weights causes uneven heating in the individual layers corresponding to the direction of heat flow. The heat flows very slowly from the outer to the inner layers, irrespective of the strip thickness, because of the resistance to heat transfer between each sheet layer, the total of which in all layers makes it extremely difficult for the heat to penetrate to the inner layers of the coil. Observations were made by Roth[1] of such resistance to heat transfer between individual layers in packs of brass sheet. It was found that with a furnace temperature of 550° C., the top sheet of a pack 500 mm. thick, consisting of 0.7 mm. sheets, attained a temperature of 450° C. within $1^1/_2$ hours, whereas the same temperature was not reached at a point 300 mm. deeper until $6^1/_4$ hours. Therefore, the sheets in the outer layers are held for 5 hours at the high temperature between 450° and 530° C. while the inner sheets have hardly attained the annealing temperature during the same interval. These differences in the heating of the individual sheets manifest themselves in corresponding uneven deep drawing properties and variations in grain size, or the surface quality of articles drawn from the sheets. These conditions are similar in a heavy coil of strip which is annealed as such.

The Continuous Strip Furnace

These difficulties led to the development of the so-called continuous strip furnace, through which the material to be annealed passes in a single strip. The continuous strip furnace[2] offers the theoretical possibility of annealing the entire strip uniformly over its whole length. For any one material and the same furnace, the annealing temperature for the entire length is dependent only on the furnace temperature and the speed of travel of the strip through the furnace.

The continuous strip annealing process entails more labor expense, but on the other hand not only insures a homogeneous anneal of the entire strip but opens up new metallurgical possibilities by providing especially favorable heat treatment conditions for the strip to produce definite physical properties. The very large surface area with respect to its weight permits extremely fast heating of the metal strip compared with previous annealing methods. The annealing time can be measured accurately in seconds by means of a controllable speed of travel. By providing suitably long insulation in the unheated or weakly heated outgoing end of the furnace, the metal strip can be tempered for a definite period of time and annealing temperature. These 3 factors can be accurately regulated not only individually but in combination with each other, which permits obtaining in practical operation the most suitable heat treating conditions as set up in the laboratory for producing definite properties in the material.

Unfortunately, for practically all metals and alloys such special heat treating conditions are not available because of a lack of stimulation in the industry heretofore. The industry has not demanded such close tolerances for the heating conditions simply because there existed no possibility prior to the continuous strip furnace for performing such annealing under practical conditions.

An example of the possibilities in controlling the annealing temperature by varying the speed of travel is shown in a test made with brass strip—0.2 × 30 mm.—for snap fastener manufacture.

The copper content of this strip was 61%. The furnace temperature was 800° C. The strip was first passed through with a speed of 6.5 meters per second. With this speed a very excellent deep draw value (Erichsen Test) was obtained,

Fig. 5. Continuous Strip Annealing Installation.

considering the low copper content. This was t = 8.4 mm. whereas the specified value was 7.1 mm. Furthermore, the cup of the ball was very smooth as is clearly shown in Fig. 1.

The microscopic structure shows a very fine grain. Due to the low copper content, it consists of about the same parts of α and β-crystals. Fig. 2 shows a line structure due to the rolling stresses.

The same test was then made with a strip speed of 5 meters per minute. The resulting anneal is entirely different from the previous one. Not only did the deep draw value recede (Erichsen), but the cup drawn by the ball was very rough—Fig. 3.

Apparently the temperature rose to a point where the brass was in the range of pure β-crystalline mixture. This caused the formation of large polygons, which on subsequent cooling were mixed by the separation of needle shape α crystals. The creation of the large β-polygons produced a particularly coarse grain structure as compared with the first annealing results.

In Fig. 4, which has the same magnification as Fig. 2, these polygons cover approximately half the area.

It would be interesting to investigate the dependence of deep-drawability (measured by the Erichsen Test) and the grain size on the rate of heating and time of annealing at a definite temperature, and on the cooling rate of the strip or sheet, for a number of metals—above all for the commonly used deep drawing brasses and copper.

Recognizing the advantages of the continuous strip annealing furnaces for brass, copper, nickel-silver and aluminum, several of the larger German mills have already placed such continuous strip furnaces in successful operation. (See Tama, *Zeitschrift für Metallkunde*, Vol. 21, Mar. 1929, pages 77-86.) Fig. 5, shows an electrically heated continuous strip furnace, having a production of 6 tons in 24 hours.

The material annealed in this furnace shows such improved quality with reference to the uniformity of anneal and highest deep drawability with a fine grain structure, that the somewhat higher labor cost has been over-balanced many times.

Furthermore, the labor cost may be considerably reduced in the continuous strip annealing process, by combining the pickling, washing and drying operations. A layout for this is shown in Fig. 6.

Most continuous strip furnaces are being built for electric heating. Electric heat has the advantage of an accurate and simple temperature regulation required for the continuous strip process. In using electrical energy for the heat source in such furnaces, the highest possible efficiency must be obtained. The elongated shape of the continuous strip furnace stipulates undesirable heat losses from the furnace shell to the surroundings. By proper design of such electrically heated continuous strip furnaces, i. e., provision for good insulation and heat transfer, these units have to-day been brought to a thermal efficiency as great as 80%, so that the power consumption, for example, for 1000 kg. brass strip is 80 kwh. This extremely good efficiency can be obtained in a furnace as shown in Fig. 5.

The strip hangs in the furnace in a catenary form. This arrangement is essential in order to prevent scratching of the surface on the strip. The hang of the strip in the furnace is controlled accurately from the inlet side as shown by the circuitous roll arrangement in Fig. 6. This works in the following manner: by means of the first fixed bending roll the strip is given a definite tension in passing through the furnace and over the guide rolls on the other side of the furnace. This tension is then further accurately regulated by means of a second movable bending roll by means of counterweights.

The electrical heating element wires are fastened directly in the chamber walls. The chamber walls are about 30 mm. thick and made of a special cement having good heat conductivity in order to prevent heat storage in the chrome-nickel heating elements. The wires are wound in a spiral, and are divided over the entire heated length of the furnace so that

Fig. 6.

Fig. 7. Furnace Details. The muffle wall, about 30 mm. thick, is of burned special refractory with good heat conductivity, which avoids heat storage in strip. Powdered insulating material fills space between inner heating tube and outer shell.

the energy input per unit of furnace length is greater at the inlet side than at the outlet side. They are also arranged in various zones so that they can be disconnected at will.

By placing the heating elements directly in the chamber walls, a more simple chamber construction is obtained and also makes it possible to provide the best insulation for the furnace. The muffles are supported on the ends by insulating bricks. The remainder of the space between outer steel casing and the inner heating chamber is simply tamped with a good insulating powder. Since the heat conductivity of the best insulating powder compared with the best insulating brick bears the following relation.

$$\lambda = .1 \text{ k cal/mh } ^\circ \text{C. to} = .3 \text{ k cal/mh } ^\circ \text{C.}$$

at the temperatures in question, it can readily be seen that the insulation of this type furnace is good. For instance, with a furnace 4.5 meters long and a useful width of 500 mm. in the heating chamber the power required for holding the furnace at a temperature of 750° C. is only 3.5 kw.

The Polymorphism of Zinc

BY L. ANASTASIADIS AND W. GUERTLER

THE different results obtained by earlier investigators of the polymorphism of zinc have induced us to make further researches concerning the allotropy of zinc with the help of thermal analysis (Saladin apparatus, double mirror galvanometer).

For this research we used 99.999% zinc. The differential-galvanometer was calibrated for the highest sensitivity of ± 2° C. Each degree corresponded to 20 mm. on the silver bromide paper. A difference in temperature of 0.02° C. between the material under test and the comparison material displaced the straight line course of the curve 8 mm. on the silver bromide paper. The heating and cooling were done very slowly. Each trial required about seven hours.

Fig. 1 shows that there is no discontinuity on the heating or cooling curve. At the point *tr* the curve shows a kink, this is due to an intentional variation of temperature. According to these measurements there exists no transformation point of zinc. Now the question is how this result is comparable with the results of earlier investigators who had very evidently found the thermal effect, and indeed each investigator found different temperatures and different intensities. In our opinion it can not be doubted that these apparent transformation points of zinc were caused by impurities in the material tested. This consideration gains weight when we consider that the highest solubilities of the different impurities present in the zinc crystal are very low and therefore a small displacement of the proportion of impurities brings with itself a great dislocation of the temperature curves for the solidus and the segregation-curve of the solid solution. For a further explanation see Fig. 2.

The right corner in the back of the system of coördinates corresponds to the constituent *A* (zinc). In regard to the 2 impurities *B* and *C* their proportions are drawn in on the other axis in the direction of the arrows. With the addition of *B* to *A* we have the liquidus line *ab*, the solidus line *ac* and the segregation-curve *cd*. An impurity of the zinc with as much as *B* the point 1 indicates would cause in addition to the lowered freezing point *h* two thermal effects, *f* and *g*. With a decrease in the proportion of *B* they become more removed from one another, by raising the concentration of *B* they were brought nearer to one another until they coincided at the temperature of the horizontal *bc*. If the alloys are not in equilibrium then an impure zinc of the composition 1 will show all the 3 effects *g*, *f* and *c* together. This agrees absolutely with the results of Benedicks.

Besides the impurity *B* there may also exist another impurity *C* and indeed the last in a constant amount which the dotted section $a_1\ b_1\ c_1\ i_1$ indicates, so instead of the curves *ab* and *cd* we get the curve cut through the 3 dimension curve *abok* (liquid plane) *acli* (Solid plane) and *cdml* (Segregation plane), namely, the curve $a_1\ b_1$, $i_1\ c_1$ and $c_1\ d_2$. On account of the continual presence and about constant impurity of *C* one would observe that by a decrease in the amount of the impurity *B* not all the apparent transformation points disappear but the thermal effect i_1 is still present.

Finally a separate trial with a small percent of the 2 impurities *B* and *C* must give 3 thermal effects, namely, h_1 (more or less corresponding with the temperature a for pure zinc) g_1 and f_1 (the last 2 are strongly affected by the degree of purity) show that they are dependent on the degree of impurity. For a cored, unequalized, solid solution crystal, 3 more effects have to be added, namely two of the two binary eutectic planes and one of the ternary eutectic plane.

This short account clearly demonstrates how easily the presence of small and varied impurities not only can simulate a transformation point but in the hands of any investigator must give entirely other temperatures for the single effect according to the purity of his material.

The above has been abstracted by the authors from the more complete discussion of the questions involved in *Zeitschrift für Metallkunde*, Vol. 21, Oct. 1929, page 338.

Preparation and Some Physical Properties of Strontium-Cadmium Alloys

BY HAROLD C. HODGE* WITH OTHERS**

ALTHOUGH a number of alloys of the strontium-cadmium series have been prepared[1] there is no record of their properties except the appearance, and a few chemical reactions. Therefore taking the present interest in the industrial use of alkaline earth alloys as justification, it was purposed to prepare a large number of strontium-cadmium alloys, to determine as far as possible the thermal data, and to study some of the physical properties.

Alloys of calcium and cadmium up to 30% calcium have been prepared[2] and their properties studied. Magnesium-cadmium alloys[3] have been investigated to all concentrations. Since both calcium and magnesium form compounds with cadmium, we may expect according to Tammann's rule[5] to find compounds of strontium and cadmium.

Preparation of the alloys of strontium by direct fusion with another metal is not feasible due to the difficulty of obtaining and handling metallic strontium. The methods by which strontium alloys have been prepared may be grouped roughly as follows:

1. Caron's method of replacement from strontium halide.
2. Kroll's method of replacement from strontium carbide.
3. Acker's method of electrolysis.

The strontium-cadmium alloys were prepared, using an adaptation after Ray and Thompson[6] of the last named method, by the electrolysis of a fused, eutectic mixture of strontium and sodium chlorides over molten cadmium in a suitably wired crucible. The cadmium served as the cathode and a carbon rod as the anode. During electrolysis strontium was deposited in the cadmium and chlorine was evolved from the anode. Metallic sodium was frequently observed deposited on the crucible wall just above the cadmium alloy. Bits of sodium metal were often seen burning upon the surface of the salt bath after the electrolysis had run for an hour or more. It was found satisfactory to carry out the electrolysis at the lowest temperature at which the salt bath was completely molten due to the almost explosive tendency of cadmium to volatilize and oxidize at slightly elevated temperatures. During the electrolysis it was found necessary to refresh the salt bath periodically. Under high potentials there seemed to be a gaseous polarization which cut off the connection between the anode and the fused salt bath. Currents of 8 to 25 amperes at 4 to 20 volts were employed with best results from currents of 12 to 14 amperes at about 6 volts.

The alloys were reheated under a bath of pure strontium chloride from 2 to 3 hours and permitted to solidify in the crucibles.

Cooling curves were obtained using a thermocouple of constantan wires with a student potentiometer. The alloys were melted in an electric tube furnace using the precautions recommended by Ray.[7]

The specific gravity was determined on chill cast alloys both annealed and unannealed. A section of the casting was polished by sand paper, weighed in air and then in dry benzene of known density. The specific gravity of the alloys at 25° C. was calculated with reference to water at the same temperature.

The hardness of the alloys was determined using both the Rockwell and the Shore scleroscope hardness testers. In the Rockwell tests, a load of 50 kg. with a $^1/_{16}''$ ball was employed. The Brinell hardness tester crushed every specimen.

The surfaces of the alloys were polished, using a suspension of alumina in ether. The alloys were etched by air until suitable for microscopic examination. Further action of the air was prevented by a thin coat of dry oil.

The low current efficiency as well as the volatility of the salt bath and molten cadmium made it impracticable to obtain alloys of much greater than 25% strontium. Using a current density of approximately one ampere per square centimeter at the cathode the current efficiencies obtained are shown graphically in Fig. 1. "A" represents the variation of the current efficiencies with the

percent strontium in strontium-tin alloys found by Ray;[8] "B" shows a similar relation for strontium-cadmium alloys prepared in a chromium plated iron crucible; and "C" shows the variation for alloys of strontium-cadmium prepared in a clay crucible. Much higher efficiencies were observed using iron crucibles than using clay crucibles.

The analyses of the alloys were made using a modification of the Jellinek-Wolff[4] method. Samples of alloys containing up to 15% strontium showed negligible amounts of silicates present after reheating.

The data obtained by thermal analysis is given in Table 1. Due to the lack of precision of the apparatus used and the complexity of the phase relations in the solidified alloys, the thermal diagram cannot be satisfactorily presented. At least one intermetallic compound, probably $Cd_{12}Sr$, is present, and there seems to be indications of another, possibly CdSr. Two eutectics are noted, one at 0.9% and one at 13.8% Sr. The transitions in the solid phase are not clearly defined but may involve several forms of CdSr. In all slowly cooled specimens, with less than 6% strontium a large percentage of metallic cadmium is present.

Table 1.—Thermal Analysis Data

Strontium in Alloy %	Beginning of Solidification ° C.	Second Arrest ° C.	Third Arrest ° C.	Final Arrest ° C.
0.72	316	316		
2.59	348	316		
5.93	375	370	290	270
7.40	366	340	290	270
7.88	362	332	286	270
11.35	316		290	270
14.86	320		297	265
19.26	348	316	295	265
26.30	366	316	290	265

Micrographs of several of the alloys are shown in Figs. 2 to 10. The "chinese script" shape of the crystals is characteristic of the alloys. An inadvertent addition of a small amount of copper to 2 alloys (Figs. 2 and 8) gave an interesting segregation of the cadmium in even sized crystals of irregular outline. By annealing alloys of very low percent strontium the typical microstructure of cadmium metal appears (Fig. 7). The phenomenon of "surrounding" is well illustrated by the photograph of the alloy containing 14.86% strontium (Fig. 10) in which an arrested transformation of a higher compound is indicated. Annealing the alloys containing more than 8% Sr gave massive cadmium crystals.

These alloys exhibit the unusual combination of softness together with brittleness. The hardness of the alloys increases with increasing amounts of strontium in an irregular fashion as shown by Figs. 11 and 12. The doubly circled points in the Shore scleroscope hardness-composition curves represent the values for annealed alloys whose composition is shown after annealing. The reason for the anomalous softness of the alloy highest in strontium is not known.

The specific gravity of the alloys is shown in Fig. 13. The calculated values using the additive law are plotted on curve A, the values found for the annealed samples are interpolated by C, and for the unannealed alloys by B. An expansion after annealing was observed in many alloys of low percentage strontium while contraction accompanied annealing on all alloys of higher strontium.

The authors wish to acknowledge their indebtedness to Dr. K. W. Ray of the State University of Iowa for suggestions and for assistance in the photomicrography, and to Professor J. H. Jonte of the College of the Pacific, for his aid and encouragement.

The Plant and the Trubia Fàbrica

BY A. G.

The Trubia National Plant was originally built by General Elorza for casting guns. Since then, the plant has been extended considerably, now manufacturing guns, projectiles, cartridges, rifle barrels, blanks, rolled, forged or finished steel products. The plant comprises Steel Department, Foundry, Forge Shop, Rolling Mill, Machine Shop, Metallurgical Laboratory, Offices and Library.

The Steel Department has two acid open-hearth furnaces of 40 and 25 tons capacity, and two electric furnaces, an 8-ton Fiat and a $^1/_2$-ton 'Lectromelt. The open-hearth furnaces, placed on an elevated working platform, are mechanically charged by an electric charging machine and the gas is supplied by a battery of three Chapman type gas-producers each capable of gasifying 880 lbs. of coal per hour. The charges are made up of Swedish and Spanish pig iron and plant scrap and additions of ferro-alloys are made in the furnace. The Fiat furnace is provided with electrode economizers and the electric equipment allows changing voltage to produce either acid or basic steel according to the available scrap. The small 'Lectromelt furnace is used for research and experimental work. The movement of ladles, ingots, etc., is accomplished by four overhead cranes, two of 25 tons, one of 50 and another of 75 tons.

In the same building are installed a 3000-ton Whitworth hydraulic press and a Davis of 1000-ton capacity for forging gun tubes, shafts, and other large forgings. Several other vertical and horizontal presses are installed in other buildings for piercing and drawing of projectiles.

The Fiat Electric Furnace.

Laboratories of Nacional in Spain*

SOTO**

The Foundry is equipped with two cupolas (43 in. diameter × 20 ft. high and 27 in. diameter × 18 ft. high) two oil furnaces of 1000 kg. and 300 kg. capacity, a crucible furnace and two mold and core drying ovens. For molding there are several molding machines and a sand mixing machine.

The heat treatment of gun tubes is carried out in two circular gas fired furnaces $32^1/_2$ and $45^1/_2$ feet in height, with a quenching bath between them and an overhead crane for suspending the tubes. Four continuous furnaces are used to heat treat projectiles and at present two electric furnaces for quenching and drawing rifle barrel blanks are being installed.

To meet the rigid specifications laid down for the products of this plant, all the steps from the raw materials to the finished products must be carefully controlled. This control is carried out by the Metallurgical Laboratory, which three years ago was enlarged to include research work. The laboratory has three sections. The Chemical section has four laboratories for general analysis, a balance room and several specially equipped laboratories to analyze coal, coke and oil. The Metallographic section is equipped with two polishing machines, a Reichert microscope, an optical bench to photograph macrostructures, a Brown critical point machine and a Chevenard dilatometer. The Physical Testing section has two universal tensile, compression and transverse testing machines of 20- and 100-ton capacity, bend and wear testing machines, a repeated bending and a repeated impact bending machine for fatigue testing, a Charpy pendulum of 30 kgm., a machine for shear and transverse testing of cast iron, hardness testers (Brinell, Rockwell, Scleroscope, Herbert pendulum and Microcharacter) and two Hoskins electric furnaces for heat treatment. For cutting tests of tool steel a Mohr & Federhaff lathe provided with devices to measure the forces acting on the tool in cutting, permits a close determination of the breakdown point. A Pyrometric Control laboratory equipped with electric furnaces, rare and base metal thermocouples and a Leeds & Northrup potentiometer completes the Metallurgical Laboratory.

Coöperative Metallurgical

SOMEONE has to carry out the research work that underlies all modern technical advances. In earlier days an individual or a firm with a problem worked it out as best he, or it, could, patenting it, or holding it as a trade secret. Others, seeing the applicability of the invention, discovery or process to their own problems, modified or added to the initial findings by further investigation, and in time the new knowledge spread and was used, but it spread slowly.

To-day we must cut down the period of incubation, and apply new facts more rapidly. Since new facts are valuable to all who can use them, it is logical for all who need new facts to join in the search for them so as to have immediate knowledge of them and the right to use them. Hence joint research attack of problems of general interest is becoming more and more popular, and this is as true in metallurgy as in any other line. But what is a joint problem, and how may it best be jointly studied? And when a project is recognized as a joint one, and the proper way to attack it is clear, how may it be financed?

At one end of the scale stand problems such as those of the small farmer. Knowledge of fertilizers, crop rotation, the best diet for pigs, and so on, redounds to the advantage of millions of operators of small farms, none of whom can finance extensive research. When the multiplication factor is so great, financing and carrying out of research by the Federal and State Governments is the only feasible method. The information must be found, and once found, its application must be more or less forced upon those who should use it. Hence such organizations as the Farm Bureau.

At the other end stands a commercial group with a practical monopoly, the Aluminum Company of America, the International Nickel Company or the Vanadium Corporation of America, for example, which profits directly and obviously from its research discoveries, and can normally look to no one but its own organization to initiate and carry on research projects aimed at new uses for the material with which it deals. User experiences, ideas, and suggestions play a large part even in these cases, but the user will carry on an investigation only so far as it bears on his own problems, and the producer must round it out to make the most of its potentialities.

Even such firms as these with strong and able research departments, find many cases where the factor of credence demands joint instead of individual action. If a producer shows evidence that his product is best fitted for a given use, the user is prone to class it as advertising, and not to believe it until he himself, or another user, has independently amassed such evidence as a check. He is suspicious of data favorable to the producer coming from the producer alone, because he knows that there is an axe to grind. He expects the producer to put his best foot forward, and so he takes the producer's statement with a grain of salt. "Ask the man who owns one," and "We are advertised by our loving friends," are slogans reflecting the psychology of the consumer attitude.

There are several ways to secure consumer credence. One, ably used by the firms named above, is to do the research work so well and so thoroughly that there are no loop-holes left, and the report of the work is credible. The good effect of such treatment is enhanced when the report is given before a scientific or technical society rather than solely in company advertising, that is in a place where it must stand the barrage of open discussion, as well as pass the Papers Committee. But even then, there may be some delay in the acceptance of the facts until they are corroborated by some disinterested party.

Exactly the same data and conclusions therefrom published by a detached and obviously impartial research agency such as a government or university laboratory, or an institutional laboratory whose reputation for scientific precision and impartiality is its most precious possession, will be promptly accepted without question.

Similarly, if the project is handled jointly through a technical society where producer and consumer, as well as impartial "general interests," are represented on the committee, and the set-up is such that everyone knows that nothing can be "put across," immediate credence is gained. When specifications and research leading to specifications are concerned, this is the only satisfactory way, as its use by the American Society

Research Laboratories, Westinghouse Electric & Manufacturing Company.

Research—How?

By H. W. GILLETT

for Testing Materials shows. After a project has filtered through the committee in charge, and finally through discussion in open meeting of the full society, the findings thereon are taken as representing the real facts as found by work which has hewn to the line, letting the chips fall where they may.

But large bodies move slowly and, of necessity, with due deliberation, so that this is a rather unwieldly method, applicable to a research project only when the active direction is in the hands of a small, alert, steering committee. It finally accomplishes the maximum in credence, but seldom attains its objective very speedily.

A good example of work so handled, and far more speedily than is often the case, is the research work of the Die Castings Committee of the A.S.T.M. By splitting up the work among the laboratories of zinc producers, of makers and of users of zinc base die castings, the laboratories being sufficiently interested in getting at the facts to justify spending real money on the problem, very real advances in the quality and permanence of such castings are being made.

Another useful Committee is that of the A.S.T.M. on Fatigue Research. While it has no experimental program of its very own, it consists of men active in the field who use the Committee as a clearing house for information to the advantage of the projects with which each is concerned, and to the advancement of knowledge in that field. Its Committee reports on the "state of the art," and its collected abstracts are most useful.

A more recent A.S.T.M. project in the field of metallurgical research is that on embrittlement of galvanized structural steel. This is steered by able representatives of the steel producers, the galvanizers and fabricators, and the users of the finished product.

Major problems often transcend the scope of a single society, and fall into the hands of joint committees, generally with one of the sponsor societies exerting the major effort.

The Joint Molding Sand Committee of the American Foundrymen's Association and other societies, has done a great work in developing simple methods for control of foundry sands and in spreading their use to hundreds of small foundries which individually could not have gone very far in research. No one will ever be able to calculate the national savings due to reduction of foundry scrap that results from the work of this group.

The Joint Committee on the Effect of Temperature on the Properties of Metals, of the American Society for Testing Materials and the American Society of Mechanical Engineers is an outstanding example of useful joint action.

The Alloys of Iron Research, sponsored by Engineering Foundation, the American Iron & Steel Institute and many other societies, is actively at work trying to correlate and codify the vast amount of undigested information in the field of alloy steels, and is digging the producer and the user of alloy steels out from under the "avalanche of unrelated facts." This is organized and financed on a scale fairly comparable to the magnitude of the task.

An example of joint metallurgical investigation backed by the Government, by an educational institution and by industry, is that which was carried on at Pittsburgh by the Bureau of Mines, Carnegie Institute of Technology and the Metallurgical Advisory Board, on the Physical Chemistry of Steel Making.

That this project is no longer to be backed by the Bureau of Mines illustrates a difficulty that has to be faced in long-time coöperative jobs—the possibility of an executive of the coöperative type being succeeded by one of a more individualistic type. In this particular case, it seems odd that the Bureau of Mines should risk the loss of prestige that will result if things go on so that it becomes clearly stamped as no longer having the coöperative spirit that actuated it from the days of Holmes through those of Bain. It is hard to see what alternative project it can take up that would be of such moment as to represent as good an investment of the tax-payers' money as would a continuation of the coöperative work for and with the steel industry.

The tendency in other progressive countries is toward greater sympathy with and coöperation in metallurgical research on the part of the Government, and, if this action by the Bureau of Mines is to be taken as an index of its future

Department of Engineering Research, University of Michigan.

attitude, that Bureau is headed for a period of vastly reduced usefulness and standing. Fortunately, the Bureau of Standards still remains anxious for and responsive to the advice of industry, and always shows a fine coöperative spirit.

There are always several points of view among the coöperators in any project and usually the leaders have strong personalities. Change of leaders brings in other personalities and upsets the original conditions under which coöperation would have continued smoothly. To insure freedom from pitfalls under changed conditions, a continuity of organization is called for. Many details as to distribution of credit, ownership of results and so on, that are originally dismissed as sufficiently covered by a gentlemen's agreement, and which would hardly introduce complications if everything remained as it was at the start, ought to be very clearly expressed in a hard and fast agreement.

Lessons for future coöperative projects can be learned from those of the past and present, not only in regard to the features that proved successful, but also as to those in which difficulties were met.

Trade associations are more and more coming to the point of joint laboratory attack on problems peculiar to the industries which they serve.

The Copper and Brass Research Association, the Zinc Institute, the Malleable Iron Research Institute, the Gray Iron Institute, the Pressed Metal Institute, the Lead Institute, the Non-Ferrous Ingot Metal Institute, the Non-Ferrous Bearing Metals Research Group, and others of that ilk, are all to a greater or less degree concerned with joint technical metallurgical problems. Trade associations can often deal with a project more speedily than can a technical society, because they can practically tax their members for financial support of an investigation whose successful outcome means money in their pockets, while the society can only request contributions. But even though producers and users of a given commodity join in the work of a trade association, complications arise in allocating the work to different plant laboratories because the members, while banded together for common purposes, are more direct competitors than are the average run of society members. Moreover, the credence factor comes in because the trade association must not only secure acceptance of its findings within its own group, but must convince the general public that those findings are not colored by its desire to spread the use of its own commodity at the expense of other commodities. Hence, in general, the trade associations will do better to farm out their problems to institutional laboratories than to handle them solely in the laboratories of their members.

Besides these society and association groups of national scope banded together by community of interest, there are more compact groups, of which there are again two wide extremes. Firms such as the U. S. Steel Corporation, General Motors, General Electric and the du Pont group, for example with wide-flung interests and scattered plants, find in their own activities, necessity for joint action along research lines, and establish their own central research laboratories to serve all the plants, while maintaining control laboratories and specialized research laboratories at the various plants.

Sharply contrasted with such groups with unified financial interests are groups of competitors who band together for solution of their technical problems. The Electric Steel Founders' Research Group and the Steel Castings Development Bureau come into this category. In such cases, the existence of the central laboratory or the coalition does not do away with the need for added joint action with still other interests through technical society or trade association activities. Each line-up fits some class of problems.

Metallurgical Laboratory, Ontario Research Foundation.

These examples will show that there is an existing mechanism for joint attack on most any joint problem in the metallurgical field, or at least an existing example of some coalition whose organization and methods might be copied. Such mechanism has been brought into existence by the exigencies of the situation in most progressive countries. In Soviet Russia and to a lesser degree in Italy, joint action through Government means is pretty much forced on industry. We do not want to copy that here. In England, there is Government subvention to groups banded together for research purposes, such as the British Cast Iron Research Association and the British Non-Ferrous Metals Research Association. Joint support of the Ontario Research Foundation by industry and by the Government obtains in Canada. Germany is just full of Institutes for metallurgical research usually located at one of the Technical High Schools, and jointly supported by trade associations or local industrial groups, by technical societies and by the Government. In these countries, while there are many large firms with their own research facilities, the average firm is smaller than in the

United States, and the tendency toward joint research among a considerable number of small firms is very marked.

Joint metallurgical research is everywhere the order of the day. Nevertheless, there are plenty of problems that should still be handled individually without letting the other fellow in on them.

The differentiation between a problem suitable for joint study and one on which individual attack will be the better, usually hinges on how widely its results will be applicable, and on how much of a figure credence cuts.

If the investigation is one to show how to cheapen the production of a material already in commercial use, or how to get more uniformity of quality in its production, it is usually a matter for distinctly individual attack. If it deals with the development of a new specialty within a given industry, that ordinarily falls also into the individual class.

But if the problem deals with extension of uses for a given metal or for material made by some given type of metallurgical process, (unless the production is a very definite monopoly), the information will help all producers, it cannot be kept secret for it has no beneficial effect unless it is broadcast, and many producers can offer useful suggestions in outlining the project and in applying its results. Nor is it just that all should profit from the effort of one without helping to finance the work. Such a problem can well be handled jointly, though if a joint consciousness of the need for the information does not yet exist, it may be such a slow process to work up interest and support that a firm which all by itself takes the bull by the horns, and develops and uses new information regardless of whether its competitors as well may profit thereby at a somewhat later date, may often cash in on its enterprise.

When the project in any direct way relates to specifications so that not one producer only, but many and many users as well, are concerned, then joint action is the only effective method, for the necessity for credence outweighs the necessity for speed.

When the new information sought relates to "fundamentals," is probably not patentable, and certainly cannot long be kept secret, and where the work required is so extensive as to be beyond the capabilities of most research organizations by themselves, then joint action registers its most direct hits. Similarly, when, as in the Alloys of Iron Research, the work obviates duplication and overlapping of effort on a smaller scale by many organizations, joint action is far more effective and cheaper in the long run than is scattered individual attack.

One psychological difficulty is met in financing joint research. Those who will profit by it are prone to feel that since other firms are equally benefited, a few hundred dollars from each is enough for any joint project, however extensive. Moreover, the project must first be "sold" to the Director of Research who may hesitate lest the allotment means skimping on some of the projects already in his laboratory, or who may fear that his advocacy of the project before his Board of Directors will be interpreted as an admission that he is not competent himself to carry out all the research in which the company should engage. After he is sold, and the question goes to the Directors, they may deliberate at greater length on an appropriation of $500 for joint research than they would over one of $50,000 for direct company research. It may be much easier to get a promise of thousands of dollars worth of work on the project in the company's laboratories than a subscription of a few hundred for work to be farmed out, although the factor of crediability may demand that it be farmed out. And too often, the Finance Committee puts the matter up as a scientific charity rather than a business proposition, though most joint projects are distinctly the latter. The way of the Finance Committee of any joint project is not particularly easy, and it may find that it has collected too much to justify giving up the project, and too little to finance it adequately.

Then there is a peculiar psychology which besets the average Steering Committee when it comes to allocating the work. While no individual on the Committee would think of entrusting a project of the importance any joint project must have to justify the joint action, to the hands of a "cub," were

Research Laboratory The Gulf Companies.

Battelle Memorial Institute.

the work to be done in his own laboratory solely for his own firm, yet he is prone, as a Committee member, to think first of handling the problem by means of a fellowship at some university where it will be directed by a professor who has little time for it from his teaching duties, and where the actual work will be done by youngsters with their eyes chiefly fixed on getting their degrees, and only looking cross-eyed at the part-time research work which pays them but a pittance. The Committee may not even contemplate remunerating the professor, figuring that he should help out "for the good of the cause." Some projects can be handled this way, but the majority demand full-time, experienced and adequately-paid effort.

A joint project that does flivver, sets the group which has started it back pretty badly, since the next time it approaches a firm for support of another joint problem, it will be asked, "What did you do with that five cents I gave you last week?"

Other drawbacks are the danger that a committee member whose firm has put a few hundred dollars into the pot, may thereby feel authorized to assume the direction of the whole shooting match, and the possibility that some contributors who do not understand that research on projects of this scope is slow anyway, and especially slow when steered by the average committee, may become disgruntled when the problem does not yield up a solution over night.

Notwithstanding all the difficulties, technical, financial and psychological, there is enough history of effective joint research action to allow appraisal of a project as to whether or not it classifies as suitable for joint attack and to let its pilots steer clear of the rocks once the project is launched.

The most important thing, after adequate financing, is not to have too many pilots, but to entrust the ship to an experienced, broad-minded and not too large, Steering Committee.

Speller*, evidently spurred on by the need for carrying on the work on Physical Chemistry of Steel Making since the defection of the Bureau of Mines, put forth an interesting proposal.

He suggested the formation, under the auspices of an association of American iron and steel manufacturers, of a Central Metallurgical Research Board which should pass upon suggested research problems of a non-competitive nature, finance them and farm them out to suitable laboratories, perhaps ultimately establishing technical institutes of its own.

Such a Board must guard against arrogating to itself the position of supreme arbiter and coördinator in such a way as to alineate rather than attract other groups. If this is avoided, so that a project which the Board does not decide to take up is not thereby given too permanent a black eye, the scheme seems well worthwhile. In a word, those firms which believe in coöperative metallurgical research, would finance it, leaving the selection of problems and the allocation of funds to a Board that would be competent to appraise the economic and technical value of the projects suggested. If such a scheme should be adopted, it would require only the initial sales work to convince the executives that the scheme was worthwhile, instead of a new sales campaign for each individual project. In this respect, the scheme offers an overhead saving similar to that accomplished by the Community Chest idea, though the object of the scheme is not charity but instead the best type of business investment. The American Iron and Steel Institute could readily create such an atmosphere that it would be considered the proper thing to do to join in.

It is to be hoped that the suggestion will fall on fertile ground even though the industrial conditions at the time the seed was sown may not provide enough "showers of blessing" to make it germinate very rapidly. The seed may well prove to return a hundred-fold, so those who are interested in the development of metallurgical research in this country will watch with interest the reception and ultimate disposition of the suggestion by the American Iron and Steel Institute.

A considerable time will necessarily elapse before this "Community Chest" idea or some other that might accomplish the ends in view, can be worked up, accepted by industry, and put into effect. The proposal, while it should ultimately afford a better way than the present, is one for the future. We still have to deal with the present, and each project must individually secure its own support. The continuity of the highly important joint projects now in hand should not be interrupted. It seems specially worthwhile for industry to provide adequately for the work on Physical Chemistry of Steel Making which has been handicapped as to funds by the withdrawal of the Bureau of Mines, and for such projects as those of the Joint High Temperature Committee on Effect of Temperature on the Properties of Metals. There is no trade association in existence with power to tax its members that can handle the financing of such projects, and the supporting group has to be built up around the particular problem, as has occurred in regard to the two projects named.

Where such groups have been built up and are going concerns with much fine work to their credit, it is certainly a good investment to keep them going.

Molybdenum Cushions Protect Tantalum Carbide Tools

A new method of applying carbide tips to cutting tools has recently been perfected by Ramet Corporation of America, North Chicago, Illinois, and is now being used in many of the tantalum carbide tools manufactured by this company and its licensees.

An insert of pure molybdenum metal is brazed between the steel shank and the tantalum carbide tip. Molybdenum having almost the same coefficient of expansion as the tantalum carbide alloy known as Ramet, the use of molybdenum inserts effectively prevents strains being set up or cracks developing in the cutting tips as tools cool after the brazing operation.

Such strains as may develop between the molybdenum insert and the steel shank are entirely absorbed by the molybdenum, due to its great ductility.

Molybdenum inserts are especially desirable in tools where the carbide tips are long, thin or of unusual shape; or where unusually severe conditions of operation are expected.

In small tools the tantalum carbide tip is now often mounted on a shank of solid molybdenum.

Savings of approximately $16,000 a year are realized from salvaging metals from ashes produced in the scrap incinerator at the Schenectady plant of the General Electric Company.

The ashes, instead of being loaded into a dump car and delivered to the dump, are first run through a ball mill, where they are pulverized, the larger pieces of metal passing out of the mill and over a magnetic separator, which separates the magnetic scrap from the non-magnetic material, which consists of copper, brass, aluminum, etc.

The finer material which is discharged from the ball mill passes over an inclined, longitudinally grooved "concentrating table," which has a stream of water flowing crosswise of the material.

The metal being heavier than the ash, slides down the bottoms of the grooves and falls off the lower end of the table, while the ash is washed off the side of the table and is then pumped through a "dewatering cone" which discharges the dewatered ash in a dump car. The ash is used for filling in low ground and the metals and concentrates are sent to the smelter or sold as scrap.

By this method approximately 100,000 pounds of ashes are ground and washed and from 20,000 to 25,000 pounds of metals and high grade smelting material is recovered each month.

The Status of Chromium Plating* by W. Blum**

AN EXTENDED ABSTRACT BY H. W. GILLETT

The properties of chromium make it suitable for various applications, unfitted for others. Its hardness gives it wear-resistant properties, but its brittleness must be considered in wear-resistant use. To some degree, these properties are under control by varying the temperature of deposition. Since the thermal expansivity is low, the coating may become detached on heating. Heating expels the hydrogen co-deposited with the chromium and causes shrinkage and softening. More knowledge of the factors governing the hydrogen content is needed.

The metal has high reflectivity in the ultra violet. Its value for ordinary use as a reflector depends on its resistance to tarnish, due to its surface film of oxide. Its electrical conductivity is high, but it makes a poor electrical contact because of the oxide film upon it. Its resistance to wetting extends not only to aqueous solutions but to molten metals also, so it is difficult to solder.

Since plated chromium coatings are porous and often contain fine cracks, they are not sufficiently impervious to protect underlying steel from corrosion. They are oxide coated in the passive state, and do not give anodic protection. Hence, coatings of softer metals such as copper and nickel that can be buffed to close up pores are essential as basis for the top coating of chromium applied for looks, tarnish resistance and resistance to wear. A top coat 0.00002″ thick is generally used in automobile practice, over 0.001″ of copper plus nickel.

The porosity of a chromium coating can be measured by depositing copper upon it. The copper deposits only at pinholes and cracks (See Fig. 1). Using this as a means of evaluating the continuity of the coating, it is shown that deposition at high temperatures and high current densities avoids porosity and cracking.

Fig. 1. Cracks (lines) and pinholes (spots) in 0.00011-in. chromium coating on nickel brought out by copper plating. 100×.

The plating conditions as to temperature and current density for a bright deposit depend not only on the bath but also on the nature and condition of the cathode. The notoriously poor "throwing power" is combated by auxiliary anodes or other mechanical arrangements of anode and cathode so as to produce more uniform distribution of current.

The solution is 250 to 400 g./l. CrO_3, with the SO_4 ion present in amount from $^1/_{100}$ to $^1/_{200}$ of that of CrO_3, is generally operated at about 45° C. and at 10–15 amp./dm.^{2} The presence of trivalent chromium decreases the range for bright deposits, and its presence is less likely with an antimonial lead than with an iron anode. An alloy of 94% Pb, 6% Sb is preferred.

Cost of chromium plating is due only in small degree to the cost of the metal deposited, but instead to the low current efficiency, some 15%. About 15 times as much current is required to deposit a given thickness of Cr as of Ni. But the decorative coatings are so thin that current costs less than $^1/_4$¢/ft.^{2} Cost of depositing a suitable nickel base coating for reception of a chromium coat is higher than when nickel is to be used uncoated as a better deposit is required. The cost of polishing is greater than the plating cost.

The CrO_3 solution causes sores, especially on the nasal septum, hence, spray carried off by the evolved gas must be taken away right at the source by suction ventilation.

As to future automobile uses, stainless steels are likely to displace chromium plating for nuts and bolts, running board trim, and similar parts subjected to severe abrasion, while stainless-clad duplex steel is promising for bumpers. For radiators and lamps, plating will continue to compete. Use of all these different products in uses to which they are best fitted rather than that of one product for all shiny parts of the car is probable.

On plumbing, it appears better to plate over a preliminary nickel coat than on brass direct. Plating on 18% Ni brass has advantages. Deposits from hotter solutions will probably have better wear resistance. Hydrochloric acid used to clean tile is fatal to Cr plating.

Coatings on zinc or aluminum have better brightness and protective value if deposited over a preliminary coat of nickel than when put on direct. Difficulty of getting true corrosion resistance in a coating of Cr or of Cr over Ni hampers its application to food containers, but no danger is apprehended from presence of traces of Cr salts in food.

The decorative uses of Cr increase the cost of the article plated. Its use for wear resistance prolongs the useful life so the cost is amply justified. The value of chromium plated gages is thoroughly established. It is useful on tube-drawing dies for Cu and Ni. Galling is prevented. It is resistant to wear and corrosion on dies for molded plastics.

Dies for forming operations involving heavy impact can successfully utilize only a very thin Cr coating. On dies for nickel coinage, a thick coating was detrimental, a thin one advantageous. Rolls for forming soft metal foils can well be Cr plated, but not for rolling steel.

Cr plating is useful on knives and saws for wood, rubber and the like, but not on metal cutting tools.

Chromium surfaces on printing plates and on electrotypes for large editions are highly advantageous.

While chromium plate is used on the piston pins of some automobiles, the brittleness of the deposit bars its use from most bearing surfaces, though deposition at higher temperatures may help. Plating the bores of 6-inch guns with 0.0004″ Cr increases life and accuracy.

New uses are likely to be found in service requiring both corrosion and wear-resistance when Cr plating is applied to base metals themselves suitably resistant to corrosion.

Fig. 2. Copper 79.70, Aluminum 1.96, Nickel 1.25, Zinc (diff.) 17.09. Annealed 600° C. Etched with $NH_4OH + H_2O_2$. 75×.

Nickel in Aluminum Brass

Condensed from article by W. B. Price by H. W. Gillett

In a pamphlet, "Alcunic Condenser Tubing," privately printed by the Scovill Manufacturing Company, W. B. Price presents 15 curves showing the properties conferred upon aluminum brass of around 20% Zn, 2% Al, 78% Cu by substituting about 1 to 2% Ni for some of the zinc, and raising the copper to about 80%.

The cold-working properties are not much affected by this change in composition, but on annealing at 500° to 600° C., a marked difference appears. Material rolled to 8 numbers hard, annealed and tested at room temperature, gave the following results.

	Al Brass A		Alcunic F		High Zn Alcunic G	
Cu	77.4		80.8		70.6	
Zn	20.0		15.1		25.9	
Al	2.6		2.2		2.1	
Ni	..		1.9		1.4	
	Tensile	Elong. %	Tensile	Elong. %	Tensile	Elong. %
Hard	103,500	3½	107,300	3½	112,600	3
Annealed 500° C.	62,700	46	79,200	25	85,500	23
Annealed 600° C.	54,200	62	69,300	30	72,400	39
Annealed 700° C.	51,500	65	57,400	47	59,700	57
Annealed 800° C.	48,000	62	56,400	52	47,900	53

The very fine structure of alloy E of 80% Cu, 17% Zn, 2% Al, 1% Ni annealed at 500° C. is shown in Fig. 1. This does not at all resemble the recrystallized structure of aluminum brass annealed at 500° C. At sufficiently high annealing temperatures, the usual type of structure appears, as is shown in Fig. 2, though the grain size is smaller than would be the case in the absence of Ni. It is postulated that at 500° there is a precipitation of some nickel compound which would account for the greater strength and lower ductility of the alloy. This suggests the suitability of such alloys for high temperature service. Results of short-time high temperature tensile tests are given below:

	Al Brass B		Alcunic E		High Zn Alcunic G	
Cu	77.3		80.1		70.6	
Zn	20.6		16.8		25.9	
Al	2.1		2.1		2.1	
Ni	..		1.0		1.4	
Temp. of Test ° C.	Tensile	Elong. %	Tensile	Elong. %	Tensile	Elong. %
25	81,500	17	100,500	14	91,600	16
300	55,000	3	85,000	1	65,000	1
500	10,100	63	16,600	40	24,900	4
750	3,300	88	4,200	101	2,700	40
875	1,800	89	2,000	142	650	37

The strength of the alloy E at the higher temperatures is notably improved by the Ni, and at the highest temperatures, the ductility is very high, indicating the good hot-working properties of the alloy.

The high zinc alloy G, unlike the other alloys described, which are all alpha, is a mixture of alpha plus beta. It has high strength but low ductility at 500° C., but its strength drops so rapidly from 600° up that it extrudes with great ease.

The 80% Cu, 17% Zn, 2% Al, 1% Ni alloy is claimed to be especially useful for condenser tubing, as it can be expanded into the tube sheet without splitting, without necessity for torch annealing. It is stated to have less tendency to season crack than the nickel-free alloy, and to be very resistant to corrosion. Beside its adaptability for condenser tubing, it is expected to serve some purposes in the oil industry on account of its high-temperature properties. Comprehensive corrosion tests are under way and are to be reported later. While data on corrosion resistance and an explanation of the exact mechanism by which nickel exerts its influence upon annealing are not yet available, the information so far available indicates a rather specific effect of nickel.

Much more extensive information is given in the curves and tables of the pamphlet than has been included in this review.

Mr. C. B. Woodworth, Manager, Railroad Division, Vanadium Corporation of America, Straus Building, Chicago, Illinois, died suddenly at his home on October 24th.

Mr. Woodworth was graduated in Mechanical Engineering from Purdue in 1907. From then until 1916 he served in the Mechanical Engineering Departments of the Wabash and the Baltimore & Ohio, passing through various grades from machinist to general foreman of the Montclair shops of the Baltimore & Ohio. He then entered the employ of the American Arch Comany with whom he remained until 1918 when he was commissioned Captain of Engineers, U. S. Army. He served fifteen months with the A. E. F. on railroad work in France. Upon his return to this country he joined the Foreign Sales Department of the American Locomotive Company and spent six years in the Argentine and Brazil, engaged in sales and service work. In 1926 he went with the Premier Staybolt Company as special technical representative, from which position he joined the Vanadium Corporation of America in May 1927 as Manager, Western Division. In August 1930 Mr. Woodworth was made Manager of the Railroad Division of the Vanadium Corporation. Mr. Woodworth was buried in Fort Wayne, the place of his birth.

CURRENT METALLURGICAL LITERATURE ABSTRACTS

These abstracts are not critical, but merely review developments. The classification number at the end of each abstract will be of assistance in mounting them on filing cards.

GENERAL (0)

Status of Alloy Steel Castings. DAVID ZUEGE (Sivyer Steel Casting Co.). *Iron Age*, Vol. 125, May 1, 1930, pages 1294–1296.

According to American Iron and Steel Institute statistics approximately 5% of total American output of steel castings was alloy steel. In 1928 about 14% was alloy steel castings. Largest demand is for small sized castings. Two main groups of alloy steel castings: First group consists of steels having small % of Cr, Ni, V or Mo, also those having Mn and Si in larger quantities than is found in carbon steels. The second group includes those having definite properties and containing usually a high% of special alloying elements. Chrome steels with a C content of 0.35 to 0.55% and Cr content of 0.75 to 1.50% resist abrasion. Complex alloy steels contain about 0.75 to 2% Cr with small % of other elements. Mo is replacing Ni and V in many compositions. Properties of alloy steels have not been developed to the highest degree. VSP(0)

Rare Metals. H. W. GILLETT. *Metals & Alloys*, Vol. 1, August 1930, page 643.

An editorial. Recent observations on copper-beryllium alloy, a market for indium, a German patent on aluminum-gallium alloys, lithium as an alloying element for lead and aluminum, advertised uses for zirconium and tantalum indicates prospect of increasingly greater usefulness of the "Rare Metals." ESC(0)

Recent Metallurgical Research. JOHN S. L. ARCHBUTT. *Foundry Trade Journal*, Vol. 42, April 24, 1930, page 308.

Abstract of paper read before Institute of Marine Engineers in London on "Recent Metallurgical Research in Relation to Marine Engineering." Reviews progress made during the last decade in both ferrous and non-ferrous metallurgy. See *Metals & Alloys*, Vol. 1, Oct. 1930, page 791. VSP(0)

Research. CHARLES M. A. STINE. (E. I. du Pont de Nemours & Co.) *Mining & Metallurgy*, Vol. 11, May, 1930, pages 261–263.

From address before New York section A.I.M.E. The general public has become "research conscious" to an extent which allows the use of research as a selling point in advertising and has revolutionized our daily life. Capital now employed runs into the billions of dollars. A survey conducted by the National Research Council on the value of research to industry, showed that out of 800 manufacturers only three were of the opinion that it did not pay. Metallurgy is the key industry. Chemical industry is dependent on products of metallurgical industry. In connection with metallurgical research, a close dependence between fundamental and applied research exists. One of the most outstanding tendencies in research consists in greater expenditures for fundamental research. VSP(0)

Chemical Analyses. *Metallurgist*, Aug. 1930, pages 113–114; *Iron Age*, Vol. 125, May 22, 1930, pages 1536–1537, 1578.

Issue is taken with Dr. John Johnston, Director of Research, U. S. Steel Corp. who in an address, "Some Comments on Steel Specifications," before the American Iron and Steel Institute in May emphasized mechanical testing and the treatment of steel rather than close working to chemical specifications. Fine limits in respect to sulphur and phosphorus were particularly challenged, quoting tests of the A.S.T.M. on these elements. The viewpoint of the author is that such tests are not conclusive unless supported by service results and experience. Physical tests in laboratories are not sufficiently imitative of service conditions to allow final conclusions based on them alone. "Dr. Johnston rightly attaches great weight to the effect of the structure of steel on its engineering value, but it is interesting to notice that he appears to be content to allow structure to be judged by the results of mechanical tests, and that he does not directly advocate the examination of that structure—i. e., the use of microscopic examination as a specification test." A steel high in sulphur in which the sulphur, to a large extent, is present in the form of non-metallic enclosures which are drawn out into elongated globules or strings of globules may give satisfactory tensile and impact tests—generally longitudinal tests—but such a bar is ready to fail, e. g., under alternating torsion, because of the effect of the enclosures in initiating fatigue fractures by their "notch action." Phosphorus which occurs in a more or less segregated form in the carbon-free bands of low-carbon steels seriously influences the transformation phenomena in steel and, in conjunction with silicon, may create bands or zones in which no transformation can occur at any temperature, and into which also no carbon can diffuse. Rigid chemical specifications are considered a safeguard of considerable value and should not be relaxed until more conclusive service information is available. For abstract of Dr. Johnston's paper, see *Metals & Alloys*, Vol 1, Oct. 1930, page 791. VVK + VSP(0)

Problems of Steel Plant Metallurgy. WILFRED SYKES. *Mining and Metallurgy*, Vol. 11, May 1930, pages 256–260.

Presented before joint meeting open-hearth conference and Chicago section A.I.M.E., Nov. 1929. Discusses the many and varied problems presented by the blast furnaces, open hearths and blooming mills. Operation of a blast furnace is very complicated. Cites work of R. S. McCaffery on the mineralogical composition of slags and methods of calculation so composition of slags can be determined as mixtures of compound rather than as a gross chemical mixture. Content of scrap used. Investigations needed in the open-hearth are: the determination of the properties of slags and reactions between slags and steel. Another important phase needing attention is rapid tests which will enable the melter to determine condition of heat. Handling of steel in soaking pits can greatly effect quality of the product. Study of the flow of metal during rolling needs further study. Causes of snakes on plates. Importance of research in steel production. VSP(0)

PROPERTIES OF METALS (1)

Radium—(I) Its Nature and Uses. PAUL M. TYLER. *Canadian Mining Journal*, Vol. 51, Sept. 19, 1930, pages 915–918; **(II) Occurrence and Exploitation.** Sept. 26, 1930, pages 869–872.

A summary descriptive of the element, its effect on the views of the constitution of matter, its use in medical therapy and how it is obtained. The ores of radium are uranium ores of three general types: (1) uraninites; (2) niobium-titanium tantalates of the rare earths and uranium; and (3) secondary minerals. The characteristics of each type are noted, also means of extraction of radium salts. The best medical opinion seems to favor the using of radium in large dosages and considers a distribution of larger amounts where competent specialists and well equipped laboratories may be maintained. WHB(1)

Manganese: Its Rise and Progress in Industry. PERCY BONDS. *South African Mining & Engineering Journal*, Vol. 40, Nov. 30, 1929, pages 339–340; Jan. 11, 1930, pages 505–506.

A review. AHE(1)

Rolling and Annealing of Pure Aluminum. (Incrudimento, laminazione e ricottura dell'alluminio puro.) P. TUCCI. *La Metallurgia Italiana*, Vol. 8, May 1930, pages 561–570.

After a brief review of the fundamental principles of rolling industrially pure aluminum, the author gives the results of a series of researches he made at the Royal School of Engineering Torino, Italy. His results show the relation between the mechanical properties of aluminum and the annealing temperature. Aluminum used by the author contained; 0.19% Fe, 0.21% Si, 0.01% Cu, 0.16% Al_2O_3 and 99.43% Al. He states that Al_2O_3 was determined by reduction with hydrogen. Gives a series of comparative curves of tensile strength and elongation of specimen after annealing at different temperatures. It is interesting to note that these properties are mostly affected when the sample is heated to a temperature of about 200° C. GTM(1)

PROPERTIES OF NON-FERROUS ALLOYS (2)

Aluminium Alloys for Heat-Treated Castings. ROBERT J. ANDERSON. *Metallurgia*, Vol. 2, Aug. 1930, pages 129–132 and 154.

Discusses alloys suitable for heat treating in the cast condition, their metallography, properties and heat treatment. Tables give the mechanical properties of some cast alloys after various treatments. JLG(2)

The Invention and Characteristics of Silumin. W. VON EICHORN. *Chemical Age*, Vol. 23, July 5, 1930, Metallurgical Section page 3.

Abstracted from *Metallgesellschaft*, May 1930, pages 17–21. See *Metals & Alloys*, Vol. 1, Nov. 1930, page 841. VVK(2)

Anti-friction Alloys. (Les Alliages antifrictions.) FRANCOIS ROEKAERT. *Aciers Speciaux, Métaux et Alliages* Vol. 4, Aug. 1929, pages 371–376; 1929, pages 470–482; Dec. 1929, pages 583–589.

The author discusses general properties of anti-friction alloys, tests of anti-friction metals and alloys, different types of anti-friction alloys, alloys with a Sn base, alloys with a Pb base and special alloys. The ternary diagram (after E. Heyn and O. Bauer) of the system Sb–Pb–Sn is given. Many photomicrographs of the alloys are included. Variations in physical properties are shown graphically. Includes bibliography. (2)

Non-ferrous Metals as Conductors of Electrical Energy. (Nichteisenmetalle als Leiter für elektrische Energie.) R. HINZMANN. *Metallwirtschaft*, Vol. 9, June 20, 1930, pages 534–535.

Specifications for copper, bronze, aluminum and aluminum alloys are given, covering allowable impurities, electrical resistance, tensile strength and elongation. The effect of several impurities in various percentages on the properties of copper are given in tabular form. CEM(2)

PROPERTIES OF FERROUS ALLOYS (3)

Cast Iron Refuses to Step Aside. O. W. POTTER. *Iron Age*, Vol. 125, May 1, 1930, pages 1281–1284.

Cast iron has run the gauntlet of the ages and has survived the combined efforts of innumerable alloys and materials to replace it. Structure of cast iron is greatly influenced by Si, C, P, S, etc., and by melting and cooling conditions. Compressive strength of cast iron ranges from 80,000 to 200,000 lbs./in.^{2} Properly made cast iron will have tensile strength of from 25,000 to over 60,000 lbs./in.^{2} depending on its chemical composition and structure. Has high rigidity. Cast iron corrodes about $^1/_2$ as fast as ordinary steel, and only slightly faster than wrought iron. Low abrasiveness and hardness of white cast iron makes it adapatable for car-wheels, brake-shoes, chilled rolls, chilled plows, etc. Strength properties are unaffected by temperatures up to 800° F. Between 800° F. and critical temperature some change of structure but no great change in physical properties. Gray cast iron is probably the only alloy that can function as a bearing without lubrication. Freezes 150° F. below melting temperature. Shrinkage is low. Segregation can be overcome. Heat treating and alloying offer great possibilities for improving cast iron. VSP(3)

Current Progress in Malleable Iron. ENRIQUE TOUCEDA. *Iron Age*, Vol. 125, May 1, 1930, pages 1297–1298.

Comparative tests of malleable iron with steel bolts showed that tensile properties of the former are higher, and resist corrosion better. Most outstanding development in the direction of metallurgical apparatus is the air furnace recuperator designed and built by Carborundum Co. In 23 heats the average coal consumption was reduced from 918 to 591 lbs. per ton of iron melted. Use of electric annealing oven cuts down the time. Rotary melting furnaces are used in Europe. VSP(3)

Nickel Chromium Alloys. JOHN H. RUSSELL. *Metal Industry* (London), Vol. 36, April 4, 1930, pages 377–379; April 18, 1930, pages 429–432; *Journal Birmingham Metallurgical Society*, Vol. 10, July 1930, pages 187–209.

Three classes of Ni-Cr alloys are recognized: (I) the pearlitic group containing up to 8% Cr and Ni in toto. (II) the martensitic group containing between 8 and 20% Ni and Cr, (III) the austenitic group containing up to 25% Cr and Ni. This latter group is divided into two classes, namely, alloys containing over 50% Fe and those containing over 50% Ni. The high Fe alloys begin to show marked brittleness in the region 500–900° C. with a maximum at 700° C. This brittleness persists on cooling. The only way of avoiding this is a carbon free alloy. They resist corrosion of a wide range of mineral and organic acid. Alloys with high Ni are not so resistant to S and HNO_3 but do not possess the brittleness. Of the heat resisting Ni-Cr alloys the 80–20 is the most widely used. English manufacturers add no Mn but American and Continental up to between 1.5 and 2%. A typical alloy, Ni 65, Cr 15, Mn 1, Fe 19, can safely be used as a heating element up to 900° C. in air. The specific resistance of Ni-Cr alloys is 100–110 microhms/cm.^{3} Corrosion resistance is due to protective oxide coating in the first heating. The production is very difficult due to wide solidification range, and a bottom pouring ladle is recommended. Mg is the best deoxidizer. Electric furnaces are used for heating. It is impossible to roll cast ingots so forging must always be resorted to before rolling. A sulphur free atmosphere is required during forging and rolling. The rolling temperature is 1200° C. Wire drawing can be performed as with ordinary steel wire but it is very important that the wire be homogeneous. The highest quality of diamond dies are required and the rate of drawing must be slower than for Cu or Fe wire. Tape is made by passing through flattening rolls. The superficial oxide coating is best put on at the factory rather than after the wire is subjected to use. In casting fluidity may be obtained by adding C, Si or Al. Includes discussion. HCD(3)

New Products

Special 300 Ampere Welders

The Westinghouse Electric & Manufacturing Company, East Pittsburgh, Pa., announces a special type of portable 300-ampere, single-operator welder, for field and street service, which can be towed or transported from job to job at road speeds, thus providing quick and ready transportation. The machine is particularly adapted for use by public utilities, street railways and other concerns whose work is widely scattered.

The standard single bearing 300-ampere, single operator Flex-Arc welding generator is coupled to a four-cylinder gasoline engine operating at 1450 r.p.m. The generator operates on the variable voltage, constant current principle, with a separately excited shunt field. The exciter is overhung from the rear generator bracket. The control which consists of field rheostat, ammeter, and voltmeter is enclosed in a sheet metal cabinet and mounted on top of the generator frame. The four cylinder gasoline power unit has an S.A.E. rating of 28.9 and 42 brake horsepower at 1450 r.p.m.

The power unit, generator, exciter and control are all enclosed in a sheet metal canopy with removable sides. Heavy-duty, pneumatic-tired wheels and spring-borne running gear parts are attached to the welded channel base. The front wheels are steered by use of radius rods and king bolt construction with an adjustable steering rod for hand or trailer service.

The overall dimensions of the complete unit are approximately 93″ × 60″ × 72″ and weighs approximately 3200 pounds.

Huge Ore Unloaders at Toledo

Electrically-driven unloaders that pick up seventeen tons of ore at a bite, and that bite every 50 seconds, recently erected on the Chesapeake and Ohio Railroad Docks, Hocking Valley Division, at Presque Isle, Toledo, are the latest step in mechanization of the age-old, time-consuming business of transferring cargoes from ship to shore; and are the first unloaders to be operated by alternating-current.

The vast amount of ore and coal handled by the lake ports has made it necessary and profitable to trans-ship by efficient electrically operated machinery. Docks in Toledo alone last year handled over 16 million tons of coal and almost 2 million tons of ore. The extent of this navigation on the lakes may be judged by bearing in mind that other docks are doing a somewhat similar business.

Fig. 1.—The Unloaders Span Four Tracks, and Are Fed by the Lines Seen at the Extreme Right of the Photograph. Pusher Locomotives between the Main Tracks Move the Cars to Be Loaded into Position beneath the Span. One of These Cars Is Seen at the Extreme Left of the Photograph, and the Other Is Shown in about the Center

Although the docks at this particular slip can take three boats, only one at a time can be unloaded with present equipment. Future installations are contemplated. The present installation consists of three stiff-legged hoists, each with a capacity of 1200 tons an hour. With all three unloaders in operation, a boat of beam up to 65 ft. can be unloaded at the rate of 3600 tons an hour. A crew of only three is required for each:—an operator, an oiler and a weigher.

Fig. 2.—The Automatic Substation for the Pusher Locomotives. The Generator Is Rated at 375 Kilowatts

The main structure of each unloader, spanning four tracks, moves on main tracks $72^1/_2$ feet apart, each track measuring two feet, center to center. The forward track is $5^1/_2$ feet from the dock. Travel is about 50 to 75 ft. a minute.

In operation, the dipper picks up the ore from the holds of the boat, and places it in a 50-ton disc hopper which discharges into a travelling scale lorry. This car, in turn, dumps it into any of the four lines of cars beneath the span. Since the ore is too heavy to be dumped on one spot on the waiting car beneath the span, it is distributed by means of a "pusher" car running between each pair of railroad tracks, which, with a lever extending on either side, is able to move the car or train of cars into proper position. This operation eliminates the necessity of moving the span.

The operator rides in a tiny cab directly above the dipper.

There are eight motors totaling 1060 hp. on each unloader. The main motions, beam hoist, and trolley travel are operated by direct current, with variable voltage control; all other operations are handled by alternating current, with full magnetic controllers.

The transformer stations are three-phase, 60 cycle, for 6600 volts incoming, and 440 volts outgoing. The electrical equipment was furnished by the Westinghouse Electric & Manufacturing Company.

New Abrasive Cut-Off Machine

This machine, manufactured by Andrew C. Campbell, Inc., Waterbury, Conn., is made for cutting steel, steel alloys, iron, non-ferrous metals, fibre and other materials. The cuts are smooth and true. The material is not damaged by heat. There is no danger of drawing the temper of the material cut. The work is held firmly in place by a fixture.

The machine is designed for safety and utility. The handle for operating the disc is arranged so that the operator may use either hand in cutting material. The starting switch is conveniently located on the motor. The belts and the disc are guarded, and there is absolutely no danger of injury to the operator. The moving parts are perfectly balanced so that but little effort is required to operate the machine. The motor is rigidly fastened

CORROSION, EROSION, OXIDATION, PASSIVITY & PROTECTION OF METALS & ALLOYS (4)

Protection against Corrosion of Pipes. (La protezione esterna dei tubi metallici contro la corrosione.) A. Rocca. *La Metallurgia Italiana*, Vol. 8, Aug. 1930, pages 757–769.

In this paper, which was presented at the 6th International Congress of Metallurgy, Mining and Applied Geology, Liege, June 1930, the author emphasizes the necessity of protecting water, petroleum and gas pipes against external corrosion. He describes a new lining which is adherent, compact and elastic. This lining consists of many layers of cement and asbestos. GTM(4)

Corrosion of Open Valley Flashings. J. R. Freeman, Jr. *Metals & Alloys*, Vol. 1, July 1930, pages 615–619.

Critical abstract of paper by K. Hilding Beij, Bureau of Standards Journal of Research, Dec. 1929. See *Metals & Alloys*, Vol. 1, May 1930, page 522. ESC(4)

Purely chemical methods for prevention of corrosion of metals. (Les methods purement chimiques de traitement des métaux et alliages contre la corrosion.) Jean Cournot & Jean Bary. *Revue de metallurgie*, Vol. 27, Sept. 1930, pages 479–485.

A brief survey of the methods of coating metals including bronzing of steel and parkerization giving some results of corrosion test in the salt spray on the latter. A mention is made of a new process for protecting Al from corrosion by a process somewhat similar to parkerization invented by Boulanger and giving remarkable protection. JDG(4)

Corrosion of Copper II. (Korrosion von Kupfer II.) L. W. Haase. *Metallwirtschaft*, Vol. 9, June 20, 1930, pages 532–534.

Pure copper is not subject to electrochemical attack. Welded Cu is attacked on account of the oxide formed in the weld, which causes a difference in electrical potential. Soldered Cu acts similarly when immersed in an electrolyte. The solder, except silver solder, dissolves. In the case of silver solder the Cu dissolves. Tinned Cu acts similar to galvanized Fe. The Sn gives good protection as long as the surface is perfect. As soon as it is punctured, electrolytic action begins. The Sn should contain very little Pb. Cu alloys act the same as Cu when soldered. Industrial waters form heterogeneous or homogeneous protection films on Cu. The first are produced by $CaCO_3$ and $MgCO_3$ deposits. These do not affect the metal. The latter are produced by dissolved gases forming an insoluble oxide, sulphide or carbonate on the Cu surface. Water should be analyzed to determine whether Cu will be suitable for tubes or pipe in contact with it. CEM(4)

Corrosion Research. (Korrosionsforschung.) E. K. O. Schmidt. *Zeitschrift Verein deutscher Ingenieure*, Vol. 74, July 1930, pages 953–954.

A special meeting of the Deutscher Gesellschaft für Metallkunde was devoted to the question of corrosion on which the author reports in short as follows. G. Masing discussed the principles of corrosion which is understood to be the destruction of the surface of a metallic body by chemical action of non-metallic materials. The process is considered to be of an electro-chemical nature. Schmidt talks of the method for testing corrosion which should imitate absolutely practical conditions. Carius gives some information on the corrosion of copper-clad steel. M. Werner discusses corrosion of lead and its significance for the general knowledge of the corrosion-phenomenon. Brenner reports on corrosion and protection against corrosion of aluminum alloys used in the construction of airplanes. He emphasizes especially that surface protection of light metals is very important as they are not resistant enough when unprotected. R. Sterner-Reiner treats corrosion of cast aluminum-alloys. With increasing purity of pure aluminum also the resistance to corrosion increases. Additions of iron and copper reduce corrosion resistance. Mg, Ti, Si and Zn are neutral, while antimony, bismuth, cadmium and magnesium increase the resistance. H. Roehrig discusses some micro-corrosion tests on aluminum and aluminum alloys and further reports some experiences with electric transmission lines which were exposed to the salty atmosphere near the ocean and the sand storms. Conductors of copper, aluminum, and aluminum alloys after 30 months showed not the least trace of deterioration. Ha(4)

The Passivity of Metals. V. The Potential-Time Curves of Some Iron Alloys. L. G. Bannister & Ulick R. Evans. *Journal Chemical Society*, June 1930, pages 1361–1374.

A study of the nature of oxide films while still adhering to the metal, using an improved method for determining the potential-time curves of different varieties, chemical and thermal treatments, in chromate and chloride solutions. In this method the specimens are placed horizontally, their edges not coming into contact with the liquids. It is found that a metal when covered with a porous oxide film may show any value of potential between that of clean metal and solid oxide. The measured potential will rise when repairing influences prevail (thickening of film, smaller or less frequent pores). The more profuse the rusting of the Fe and steel specimens the lower the initial potential. In general steels which show a final potential above 0.0 v. show no rust at the end of 3 hours, while it is produced by those steels giving negative potentials. The observed potential is not a measure of the rate of corrosion, steel and Al giving about the same final potentials, but the steel being much more quickly corroded. Consideration of the potential-time curves together with the normal electrode potential; gives information consistent with and more extensive than the results of corrosion-velocity measurements. (4)

Metals to Resist Heat and Corrosion. *Metallurgist*, June 1930, pages 83–84.

An extended abstract of a paper by H. D. Phillips appearing in *Heat Treating and Forging* for April 1930. VVK(4)

Heat-Resistant Alloys and Their Behavior to Sulphur. (Hitzebeständige Legierungen und ihr Verhalten gegen Schwefel.) H. Gruber. *Zeitschrift Verein deutscher Ingenieure*, Vol. 74, May 3, 1930, page 569.

In order to determine the behavior of different alloys to sulphur, samples were annealed in undiluted hydrogen sulphide and the absorption of sulphur determined after 1 hour at different temperatures. The following table shows the results:

No.	Composition in % Fe	Ni	Cr	Mn	Al	Designation	Increase in weight in g. at 700° C.	800° C.	900° C.	1000° C
1.	100					Iron	0.76	5.51	10	destroyed

RARE METALS AND ALLOYS

TANTALUM • TUNGSTEN • MOLYBDENUM • CAESIUM • RUBIDIUM

FANSTEEL

now offers

TUNGSTEN

IN ALL COMMERCIAL FORMS

ADJUSTMENT of former patent restrictions now permits Fansteel to offer 99.95% pure Tungsten in rod, sheet, wire, ribbon and powder. Several Tungsten alloys and salts are also available.

Fansteel, of course, has been refining pure Tungsten since 1914, but only for use in electrical contact points. Now manufacturers using Tungsten in other forms are to have the benefit of Fansteel's experience and equipment for refining and working rare metals.

Unusual purity, uniformity and workability are characteristic of Fansteel Tungsten. It has the highest melting point of all metals. It retains rigidity at higher temperatures than any other metal. It has the lowest vapor pressure of all metals, and, in the form of drawn wire, has *greater tensile strength than any other known material.*

The Fansteel research laboratory, with more than 16 years specialized experience in the metallurgy of Tungsten and other rare metals, offers assistance, without charge, on problems of application and fabrication.

STRUCTURE OF METALS & ALLOYS (5)

Metallography & Macrography (5a)

The Mechanism of the Solution of Cementite in Carbon Steel and the Influence of Heterogeneity. ERIK WALLDOW. *Iron & Steel Institute, Advance Copy* No. 10, Sept. 1930, 38 pages.

Commercial steels and especially pure Fe-C alloys were intensively studied by thermal and microscopic methods to determine the mechanism of the pearlite change. The transformation of α into γ iron in commercial steels was found to occur successively in different parts of the sample, thus causing the transformation to occur over a range of temperatures. This is explained by the uneven distribution of constituents, particularly Si. Two new forms of hardening structures are reported—hypotroostite and sorbotroostite. Contains 16 references. JLG(5a)

The Cementite Solubility Line. S. EPSTEIN. *Metals & Alloys*, Vol. 1, June 1930, pages 559–561.

A correlated abstract. A complete discussion of the data available at the present time regarding the locus of the A_{cm} line its probable relationship to other factors of the iron carbon diagram, and the available technique suitable for study of the phenomenon. ESC(5a)

Micrographic Characteristics of Light Alloys. (Caratteristiche micrographiche della leghe leggere.) G. GUZZONI. *La Metallurgia Italiana*, Vol. 8, Aug. 1930, pages 747–756.

Sixteen references. The author describes the methods of preparation of micrographic specimens in study of aluminum and its alloys. He also describes the effect of alloying element in aluminum and its structure, color, physical and chemical properties. Alloys studied for which photomicrographs are given are commercial aluminum, Al-Si, Al-Mg, Al-Mg-Si, Al-Cu, Al-Zn, Al-Ni, Al-Mn, Duralumin. For each of these alloys, the author gives a method for preparing, etching, and identifying the structural forms in the alloy. In a summarized table he shows the effect of different etching solutions on each of the investigated alloys. GTM(5a)

Contribution to the Problem of Hardening in Beryllium-Aluminum and Magnesium-Aluminum Alloys. (Beitrag zum Härtungsproblem von Beryllium-Aluminum- und Magnesium-Aluminumlegierungen.) M. HAAS & D. UNO. *Zeitschrift für Metallkunde*, Vol. 22, Aug. 1930, pages 277–279.

Be-Al alloys with 0.2, 1.0, 1.38 and 1.58 Be were prepared and studied microscopically, dilatometrically, and by means of electric resistance from room temperature to temperatures in the liquid range. It is concluded that the solid solubility at room temperatures is 0.2 Be, at the eutectic temperature 0.8 Be and that the eutectic composition is 1.4 Be. Dilatometric and electric resistance studies were made on Cu-Be-Al alloys with 0.75 Be and 4 Cu, and 1.4 Be and 4 Cu. The results are shown on graphs. Mg-Al alloys were likewise studied dilatometrically, the results confirming the equilibrium diagram of Schmid and Spitaler (*Journal Institute of Metals*, Vol. 35 (1926) page 551.) (5a)

The Structure of Heat-Treated Low Carbon Steel. WELTON J. CROOK & HOWARD S. TAYLOR. *Metals & Alloys*, Vol. 1, June, 1930, pages 539–543.

A practical investigation of 0.20% carbon steel, structural changes when quenched and subjected to various draw temperatures, analyses of samples show presence of copper and nickel. Bureau of Standards analyses of standard steel samples reveals a steady increase in contents of these elements due to use of automobile scrap. Normal transformation points are assumed to indicate no effect by the presence of these constituents. A series of bars was heated for 30 minutes at temperatures beginning at 1300° F. and increasing by increments of 50°. They were quenched in cold water. Regeneration curves, for most steels show a gradual increase in hardness, until the upper critical has been reached and then fell off sharply as it was exceeded. In this case the maximum occurs below the upper critical temperature. Microscopic photographs of these specimens are shown graphically. This indicates a tendency toward martensitization, confirmed by increase in hardness, at 1300° F. At 1350° F. complete transformation to martensite has been effected—Ac_1. At 1450°, this is becoming dilute in carbon and structure is coarsening. At 1500°, a radical change in structure has occurred—Ac_2. At 1550°, the ferrite is completely in solution. Progressive heating above this temperature indicates grain growth of the martensitic structure. A series of test specimens were then heated for various times at various temperatures, tested for Brinell hardness and examined microscopically. A plot of hardness values against draw temperature is shown. Analysis of these photographs reproduced in comparison with temperature is explained. ESC(5a)

On the Equilibrium Diagram of Lead-Tin System. K. HONDA & H. ABÉ. *Science Report of Tohoku Imperial University*, Series I (1930) pages 315–330.

The equilibrium diagram of the lead-tin system has been studied by differential thermal analysis. It was found that the maximum heat evolution at 160° C. lies at 18% of tin. As this temperature is just below the eutectic

point, the heat evolution must be due to a rapid decrease in solubility of β-phase in α-solid solution, with the fall of temperature. The diagram of this system, thus, was greatly simplified as shown in the figure. KT(5a)

Sulphur Prints. *Metallurgist*, Sept. 1930, pages 132–133.

An extended abstract of the paper by M. Niessner in the *Archiv für Eisenhüttenwesen*, Vol. 3, Aug. 1929, pages 157–161. See *Metals & Alloys*, Vol. 1, May 1930, page 523. VVK(5a)

Hot-Working and the Critical Points of Steel. *Metallurgist*, Aug. 1930, pages 116–117.

A critical abstract of a paper by Professor Seigle published in the July 5th issue of *Genie Civil*. Prof. Seigle subjected mild steel bars to severe plastic torsion at a red heat (800° C.) the amount of twist applied being in some instances as much as 1200 complete turns on a length of 100 mm. The specimen of steel was examined both before and after the hot torsion treatment by means of the Chevenard differential dilatometer. The A_3 point was very much intensified and sharpened after twisting. The effect is apparently permanent being retained after fifty cycles. The micro-structure shows no signs of distortion. VVK(5a)

METALLOGRAPHIC

AUTOMATIC POLISHING MACHINE

Bureau of Standards Design

FEATURES

Finished specimens have a plane surface and high polish with no collection of abrasive material between crystals. They will show perfect formation of inclusions free from pits and "comet-tails" such as occur in specimens that are hand polished.

One, two or three specimens are automatically polished at one time.

The machine is compact, occupying floor space 22 by 22 inches. Height overall, 43 inches.

Complete with 2 duraluminum polishing discs, one 120-grain mounted grinding wheel, 6 specimen holders, and ¼ H. P. Motor.

Price $510.00

Write for descriptive pamphlet.

The X-Ray is a New Inspection Tool

It saves thousands of dollars for manufacturers in many lines. Learn what it has to offer you

UNLIKE the human eye, which can judge the perfection of a product only by its external appearance, the penetrating x-ray "eye" has the power of detecting and locating HIDDEN flaws. Often a simple change of manufacturing methods remedies faults which otherwise might seriously affect the service of the article.

Can radiography do something of this sort for you? We will gladly cooperate with you to find out. Our facilities are adequate to put any sort of manufactured product to the necessary tests. As a first step, write for a copy of our illustrated booklet which tells of the many industries in which the x-ray has proved useful.

The Orientation of Rolled Metals of the Hexagonal System. (Ueber die Walztexturen hexagonaler Metalle.) E. SCHMID & G. WASSERMANN. *Metallwirtschaft*, Vol. 9, Aug. 22, 1930, pages 698–702.

Contains 12 references. A piece of technical sheet zinc was cold rolled in one direction to a thickness of 0.02 mm. and X-ray photographs taken at various angles to the sheet in three planes; (1) in the direction of rolling, (2) perpendicular to and (3) 45° to the direction of rolling. The photographs are summarized in a pole diagram showing the position and the intensity of the base faces. The same procedure was followed with a piece of magnesium annealed $1^1/_2$ hours at 600° C. and cold rolled to 0.3 mm. The orientation of Mg is much simpler than Zn. The formation of the orientation of the two metals is explained by the changes in the single crystal, and the characteristic difference by the difference in the mechanical twinning. The heterogeneity of the orientation of rolled Zn is proved by preliminary tests.
CEM(5a)

Atomistic Fundamental Principles of Recrystallization. (Atomistische Grundlagen der Rekristallisation.) U. DEHLINGER. (Technische Hochschule Stuttgart). *Zeitschrift für Metallkunde*, Vol. 22, July 1930, pages 221–223.

Paper presented before the Deutsche Gesellschaft für Metallkunde, Berlin 1930, deals with experiments on recrystallisation due to deformations which are carried to such degrees as to completely change the texture of the starting material. Measurements of recrystallization velocity by determinations of changes in grain size and electrical conductivity showed that at a certain temperature a sudden break in recrystallization velocity occurs. Chaotic small grains or "sliding lamellae" (proven by X-rays to be present in deformed metals) are combining under the influence of temperature to larger, adjacent crystals. This phenomenon is called recrystallization. Based on Prandtl's model of elastic hysteresis, the author assumes that the boundaries of the individual "sliding lamellae" in the deformed metal are hooked together in a metastable manner. This metastable state is overcome by a certain heat energy at a certain energy peak value. The numerical evaluation of this phenomenon proves that at low temperatures this metastable state in the small grains hooked together is abolished gradually, but above a certain temperature abruptly. Additions, the atoms of which are loosely connected with the lattice of the matrix, decrease the recrystallization temperature.
EF(5a)

Some Elementary Facts about Cast Iron. GEORGE M. ENOS. *Metals & Alloys*, Vol. 1, July 1930, pages 595–600.

A general discussion of the effects of carbon in cast iron and its various forms is given. It is observed that the presence of carbon up to the eutectic percentage lowers the melting point of alloys of iron and carbon. The iron-graphite system is termed the "stable system" largely because graphite is released in cast irons upon very slow cooling. It has not been conclusively proved that graphite would be released if only iron and carbon were present in the alloy. For the usual interpretation of structures the "metastable" system, iron-cementite diagram can be used, remembering that graphite may be produced in various ways, and that for convenience in interpretation, the matrix may be regarded as a steel. The rate of cooling of the casting is one of the most important variables in foundry practice. The forms of graphite and cementite have been listed. The influence of silicon, sulphur, manganese, phosphorus upon the iron–carbon system are also discussed at some length.

A Metallographic Investigation of the Ternary Alloys of Fe–W–C System, Part III. The Equilibrium Diagram of the Fe–W–C System. SHUZO TAKEDA. *Kinzoku no Kenkyu*, Vol. 7, Aug. 1930, pages 409–446.

By means of the thermal analysis, and the microscopic observation, the constitution of the ternary system Fe–W–C, in the temperature ranges above solidus surfaces, was thoroughly investigated and the equilibrium diagram of this system was determined, ranging up to 4% C. In this system, there exist 2 metastable phases θ and η, and 8 stable phases,

$\alpha, \gamma, \delta, \epsilon, \zeta$, graphite, W_2C and WC.
θ composed of compound Fe_3C,
η composed of compound Fe_3W_3C,
α, γ, δ composed of iron,
ϵ composed of compound Fe_2W_2,
ζ composed of tungsten.

The metastable phases are formed on rapid cooling from the melt and change to the stable phases on slow cooling or annealing. As the C content decreases, the stability of the metastable phases increases, and in low C alloys these phases are formed as fairly stable constituents, while in high C alloys readily decompose forming graphite or WC. In the metastable system, among these phases, the following reactions take place:

Monovariant reactions:
Peritectic change, melt $+ \zeta \rightleftharpoons \epsilon$; peritectic change, melt $+ \zeta \rightleftharpoons \eta$;
Peritectic change, melt $+ \epsilon \rightleftharpoons \eta$; eutectic change, melt $\rightleftharpoons \delta + \epsilon$;
Eutectic change, melt $\rightleftharpoons \delta + \eta$; peritectic change, melt $+ \delta \rightleftharpoons \gamma$;
Eutectic change, melt $\rightleftharpoons \gamma + \eta$; eutectic change, melt $- \gamma + \theta$;
Eutectic change, melt $\rightleftharpoons \eta + \theta$;

Nonvariant reactions:
Di-peritectic change, melt $+ \zeta \rightleftharpoons \epsilon + \eta$
Peritecto-eutectic change, melt $+ \epsilon \rightleftharpoons \delta + \eta$, 1380°, 28% W, 1.0% C;
Peritecto-eutectic change, melt $+ \delta \rightleftharpoons \gamma + \eta$, 1335°, 27% W, 1.4% C;
Ternary eutectic change, melt $\rightleftharpoons \gamma + \theta + \eta$, 1085°, 17% W, 3.7% C;
Peritecto-eutectoid change, $\gamma + \eta \rightleftharpoons \alpha + \theta$, 730°, 1.0% W, 0.9% C.

In the stable system, graphite, WC or W_2C take part in the place of the θ and η phases in these reactions. Several changes taking place in the ternary Fe–W–C system are thoroughly elucidated by the double diagrams, stable and metastable systems. Many sectional diagrams, projectional diagrams, a space model showing the equilibrium conditions are shown, the process of crystallization of alloys belonging to several fields of composition are tabulated, and many photomicrographs showing typical structure of respective field were attached.
TM(5b)

Air Chipper

The Kipp Air Chipper is a new device developed by the Madison-Kipp Corporation of Madison, Wisconsin. It is air driven and operates at air pressures of 60 to 100 lbs. Over 6000 blows per minute are delivered to the chisel through a turbine-valve-hammer mechanism. The chisels are inserted into the barrel and held there by means of a spring clamp. The chisel shanks are pentagon and may be inserted with any of the five sides in an upward position. The chipper itself will operate in any position, giving the operator freedom of action for clearance and convenience. The design of the air chipper eliminates vibration in the grip hand of the operator so that nervous and fatiguing strain, often associated with pneumatic chisels, is absent. The air chipper was developed to provide a substitute for the slow and uncertain hand chipping and grooving in making die casting dies. Early in 1930, the Madison-Kipp Corporation introduced the air grinder, which, like the air chipper, was first used on a variety of work in their die casting die department which this company utilizes as a practical laboratory. The weight of the air chipper is $1^1/_2$ lbs., the length is $5^1/_2$ in.

PHYSICAL, MECHANICAL & MAGNETIC TESTING (6)

Stress-Strain Relations in Impact Tests at High Temperatures. *Metallurgist*, Aug. 1930, pages 125–126.

An extended abstract of a paper by T. Sutoki in *Science Reports of the Tohoku Imperial University*, Series I., Vol. 19, No. 1. See *Metals & Alloys*, Vol. 1, Nov. 1930, page 847. (6)

New Conversion Tables Show Relations among Hardness Tests. T. N. Holden, Jr. *Iron Age*, Vol. 126, July 10, 1930, pages 80–81.

Hardness measurement conversion table applicable mainly to alloy steels. Compares hardness obtained with Rockwell using three loads, 150, 100 and 60 kg., with a diamond penetrator. Comparing with latest table of International Nickel Co. the 2 check very closely so far as they go, but this one goes further. May be of use for accurate determination of hardness of thin stock, such as razor blades. Includes table and gives examples. VSP(6)

Railway Rail Progress. H. W. Gillett. *Metals & Alloys*, Vol. 1, July 1930, page 625.

A critical abstract. Detector car tested 2908 track miles and found one fissure per 13.6. It does not detect failures smaller than a nickel. Failures after inspection indicate rapid growth of smaller fissures to failure. Trend of rail failures as projected from 1913–1919 failures led to an expectation of 1 rail failure per 2 miles of track while it actually runs 1 failure per mile due to traffic density. 1.30–1.60% manganese rails are in considerable use to prevent failure. Carnegie Steel, Edgar Thompson Works and Bethlehem are heat treating rails. Pennsylvania reports favorably upon these. ESC(6)

The Pile Temper Testing Machine. R. G. Johnston. *Metal Industry* (London), Vol. 36, March 14, 1930, pages 293–296.

The machine consists of a bed-plate carrying an upright pin, which is rigid and non-rotatable. Around this pin a lever rotates in such a way that it is always tangential to a circle having the pin as a center. Outer end of the lever passes over a quadrant graduated in degrees and carries a vernier enabling tenths of a degree to be read. Behind pin is an adjustable clamp, and along quadrant are holes for insertion of stops. In course of experimental work on successive rolling of Cu without annealing, the Pile test was used and results obtained were plotted. Made by the W.C.T. Avery, Ltd. VSP(6)

A review of the methods to determine the distribution of plane tensions in structural parts, if subject to mechanical stresses, by means of transparent models. A short description of each method is given and 23 references give the original papers. Ha(6)

The Testing of Cast Iron. J. W. Donaldson. *Metallurgia*, Vol. 2, Aug. 1930, pages 121–124.

15 references. General discussion of methods of testing cast iron. There is considerable controversy as to whether the test bars should be cast separately or cut from the casting. The types of specimens and methods of tests used in various countries are discussed. JLG(6)

Proper Testing of Cast Iron. J. G. Pearce. (British Cast Iron Research Association.) *Iron Age*, Vol. 125, June 5, 1930, pages 1679–1680; *Foundry Trade Journal*, Vol. 42, June 5, 1930, pages 413–416; June 12, 1930, pages 435–439.

Abstract of an exchange paper on "Correlation of Tests for Cast Iron" before the American Foundrymen's Association, Cleveland, May 12. Deals mainly with mechanical tests, usually specified, and with translation from one form of mechanical test to another. Includes discussion. VSP(6)

On the Behavior of Soft Steels When Exposed to Vibrations. (Ueber das Verhalten weicher Stähle bei Schwingungsbeanspruchungen.) K. Aders. *Stahl und Eisen*, Vol. 50, July 31, 1930, pages 1095–1096.

A publication on the behavior of 2 steels (steel W: C 0.08%, Si 0.05%, Mn 0.44%, P 0.023%, S 0.047% and steel S: C 0.07%, Si 0.01%, Mn 0.48%, P 0.036%, S 0.047%) in vibration tests (*Mitteilungen Forschungsinstitut Vereinigte Stahlwerke* (1929) Vol. 1, Report 8, pages 201–221) is reviewed. Steel W was melted under special precautions to produce a steel with slight inclination toward aging effects; steel S was heavily segregated. Both steels were annealed at 950° C. for one hour. The lower yield point for both steels is about the same (W: 24.7 kg./mm.², S: 23.6 kg./mm.²). The values for notch toughness, number of repeated blows before fracture and endurance tensile strength vary very much as shown in the following table. The relation between endurance strength and yield point is evidently different for both steels. This fact was found to be of importance for the reaction of the materials in testing them in a repeated bending test machine as well as of influence on the static physical properties after the steels have been dynamically tested under the application of a dynamic overload. The endurance limit of steel W was increased by 1 kg/mm.² after 5,000,000 cycles with a load analogous to the endurance limit; steel S shows no change. In applying a load 25–33.3% over the endurance limit, the endurance limit of steel W was increased, whereas the endurance limit of steel S decreased. Also the static physical properties of both steels were changed after having been tested dynamically with an overload 25–33.3% above the endurance limit. Yield point and tensile strength of steel S were increased, whereas yield point and tensile strength of steel W was not changed. GN(6)

	Notch Toughness mkg./cm.²	Number of Repeated Blows for Fracture	Endurance Tensile Strength kg./mm.²
Steel W	14.7	17,900	18–19
Steel S	1.9	24,400	24

Damping by the Material at Torsional Vibrations According to the Fatigue Testing Method and the Method of Free Oscillations. (Die Werkstoffdämpfung bei Drehschwingungen nach dem Dauerprüfverfahren und dem Ausschwingverfahren.) W. Knackstedt. *Zeitschrift Verein deutscher Ingenieure*, Vol. 74, Aug. 23, 1930, pages 1182–1184.

The damping capability of a material has, in recent years, been recognized as a valuable means for judging the behavior of a material in operation. The damping is measured as that work which is transformed into heat in 1 cm.³ of material at a full cycle of load within the limits + maximum stress to − maximum stress. Three methods are in use for determining this energy: (1) the static hysteresis-loop, determined as a function of the deformation in a cycle process; (2) the fatigue test, determined by the energy supplied by the driving engine; (3) the free oscillation test—the test rod is provided with a heavy mass and made a springy member of a vibrating system and the oscillations are damped by the damping capacity of the material. The logarithmic decrement of the vibrations permit the direct determination of the energy of deformation. The machines for these 3 methods have been developed in the Wöhler Institute in Braunschweig; these, together with the methods, are described and illustrated. Tests show that the results from the 3 methods do not differ greatly. 5 references. Ha(6)

Zinc Coatings and the Corrosion Fatigue of Steel. *Metallurgist*, June 1930, pages 86–87.

A summarizing review of the recent work on the effect of protective coatings on corrosion fatigue. VVK(6)

Corrosion-fatigue of Metals. (Die Korrosionsermüdung der Metalle.) D. Thoma. *Zeitschrift Verein deutscher Ingenieure*, Vol. 74, May 31, 1930, page 719.

The observation first made by McAdam that the fatigue tensile strength of a sample rod is reduced if its surface is moistened with water during the fatigue test, has been confirmed by new tests of the author who calls attention to the importance of this fact particularly for the design of machines. He made two tests with 3500 alternate bendings in one minute, one with an electric steel casting of 65 kg./mm.² tensile strength which had a dry fatigue strength of 21 kg./mm.², and when moistened by a water-jet of low speed gave only 14 kg./mm.². The other test with rustless steel of 66 kg./mm.² tensile strength showed an endurance limit of 24 kg./mm.² dry and 14 kg./mm.² when wet. The first steel showed strong corrosion (rust) while the other did not show the least trace of rust. Ha(6)

Fatigue of Aluminum Alloys. *Metallurgist*, Sept. 1930, pages 137–139.

Endurance Studies with the Schenck High-Frequency Tension-Compression Machine. (Dauerversuche an der Hochfrequenz-Zug-Druck-Maschine. Bauart Schenck.) K. Memmler & K. Laute. (Staatliche Materialprüfungsamt Berlin-Dahlem.) Heft 329, Forschungsarbeiten auf dem Gebiete des Ingenieurwesens, V. D. I. Verlag, Berlin (1930) 32 pages. Paper 6 RM.; *Zeitschrift Verein deutscher Ingenieure*, Vol. 74, Feb. 8, 1930, pages 180–190.

A magnetically-driven axial loading endurance testing machine of the same general type as the English Haigh machine, but operating at a much higher speed, 30,000 cycles/min., is described. At this speed, it takes but 5½ hours to run the 10 million cycles to which it is customary to extend an endurance test. Many difficulties, such as the danger of error in stress calculations due to resonance, the difficulty of calibration, the necessity of knowing the modulus of elasticity in order to calculate the load from the amplitude, that of choosing specimens of proper dimensions for each material to be tested, etc., etc., are discussed. For materials of high "damping," which develop heat during the test, an oil spray is provided to cool the test piece. Results are given on steels ranging from 0.05 to 0.80% C, in several conditions, on silicon steels from 0.10 to 0.20% and about 0.90% Si, on a 0.45% C, 4% Ni, 1% Cr, 0.80% W steel, on cast iron, nickel, copper, an Al-Cu-Si alloy (Lautal), an Al-Cu-Zn Mn, Li alloy (Scleron), and a 90% Mg, 10% Al alloy (Electron). The S-N curves had the usual shapes for the various materials studied, and the effect of understressing was quite normal. The effect, expressed in maximum amplitude of deformation of the test piece that could be withstood indefinitely, of a surface notch 0.03 mm. deep, turned on the test section was found to be a reduction of 22% for the heat-treated Ni Cr steel, 15% for the same annealed, 28% for annealed 0.05% C steel, 10 to 22% for various as-rolled steels and zero for annealed nickel and for copper as rolled. That is, the materials did not act quite as would be expected from low-frequency tests in this respect. The ratios of endurance limit to tensile strength were extraordinarily high. Ratios of 45 to 55 to which one is accustomed for steel in endurance testing at ordinary speeds, were found with some of the harder steels, but the softest steels showed ratios as high as 70 to 75 or even more. Lehr previously found much higher endurance limits on this high speed Schenck machine than at slow speeds. Some speculation is given on whether this is a real phenomenon and the authors conclude with the remark that a comparison of the same materials on this and other endurance machines must be made before the usefulness of this can be determined. Such work is to be undertaken at the Materialprüfungsamt. From the comments of the authors on the usual ways by which attempts at short cut methods of endurance testing are carried out, it would appear that they do not consider any of them of any promise and have turned to this very high speed machine as more hopeful. Since, on the face of the returns, the endurance limits determined at 30,000 cycles/min. appear to be very much on the unsafe side, unless further work shows systematic errors in methods of calibration that can be corrected, or unless an absolutely reliable proportionality factor between such results and those that would be obtained at the speeds at which the materials are actually used in service can be worked out, the utility of the apparatus would appear very doubtful. From the description, the machine would appear to require a very skilled operator, very careful determination of the elastic modulus, to be very noisy, and very expensive. Many of these drawbacks could be put up with if endurance testing could be hastened, but this type of testing machine will require much more research in "testing the test" before the speeding up of endurance testing can be taken as accomplished. The account will prove most interesting to those working on endurance testing methods. Whether any of the data so far obtained with the high-speed machine can as yet be safely used for any purpose of engineering design, seems very doubtful. HWG&Ha(6)

Compressive Tests of Bases for Subway Columns. James H. Edwards, H. L. Whittemore & A. H. Stang. *Bureau of Standards Journal of Research*, Vol. 5, Sept. 1930, pages 619–625.

In the construction of subways under the streets for carrying passengers by electric trains it is customary to provide steel columns between the tracks to support the overhead structure. These columns are usually rolled steel H-sections having plate and angle bases riveted to the columns for distributing the load on the concrete footing. Tests were made of 3 welded bases and 6 riveted bases, 3 without base plates and 3 with base plates to determine whether the welded design was satisfactory. The specimens were loaded with the base on a span of 12 inches. Some hand strain-gage readings were taken to study the stress distribution. The strength of the welded specimens and the riveted specimens having base plates was practically the same. The H-section deformed greatly at the maximum load, and the stiffeners in the base buckled. The strength of the riveted specimens without base plates was about 60% of the strength of the other types. At failure, 8 rivets on one side of the specimen sheared. There was apparently no deformation of either of the H-sections or the angles forming the base. (6)

Seams for Copper Roofing. K. Hilding Beij. *Bureau of Standards Journal of Research*, Vol. 5, Sept. 1930, pages 585–608.

The various types of seams which have been proven by experience to be suitable for copper roofing are described. Leakage tests showed that calked seams can be used wherever the depth of water which may be standing for several days on the roof will not exceed 4", a depth rarely occurring except in gutters. A small section of seam removed from a roof after many years of service stood continuously for 45 days under 12" of water without any signs of leaking. The tests proved that the maximum strength is secured by pretinning, and large quantities of solder on the exposed surface of the seams are of little value. The results of prolonged tests indicated that the maximum safe load for soldered lap seams is about 350 lbs./in.² of seam and about 375 lbs./in.² pretinned flat-lock seams. Under greater loads failure occurs after a time, depending upon the magnitude of the load. (6)

ELECTRO-CHEMISTRY (7)

Electroplating (7a)

Plating Stainless Steel. W. E. WARNER. *American Machinist*, Vol. 72, May 29, 1930, page 884.

Ordinary plating solutions are not successful for plating stainless steel with silver, copper or nickel. A good solution is one of 25% sulphuric acid. Use a lead rod as an anode and the steel as the cathode. Voltage of from 4 to 6 volts. Solution temperature from 10 to 80° F. Another solution is one of 30% hydrochloric acid. Use a carbon anode, same voltage as before, and a temperature of 140° F. RHP(7a)

Continuous Electro-Deposited Tubing. *Metallurgist*, July 1930, page 110.

The method of Prof. Billiter in producing continuous electro-deposited tubing as presented to the American Electrochemical Society in May, 1930 is described. See *Metals & Alloys*, Vol. 1, Oct. 1930, page 796. VVK(7a)

Hardness and the Polishing of Electrodeposits. D. J. MACNAUGHTON & A. W. HOTHERSALL. *Metal Industry* (London), Vol. 36, Mar. 21, 1930, pages 321–332; Mar. 28, pages 351–354; Apr. 11, pages 410–412.

Includes discussion. See *Metals & Alloys*, Vol. 1, Nov. 1930, page 841. VSP(7a)

The Contamination of Solutions. F. J. LISCOMB. *Metal Industry* (N. Y.), Vol. 28, Sept. 1930, pages 427–429.

The introduction of iron into alkaline cleaning and electroplating solutions is discussed, together with means employed to determine the sources of the contamination and the contaminating influences. All pickled work should be well neutralized and thoroughly rinsed in clean water before going to a plating tank, and tanks should be rubber lined. Cleaning and alkaline plating solutions should be free from all chlorides. Unlined tanks should never be used as anode in any cleaning or plating solution. All electric cleaning and plating solutions should be tested with steel electrodes to note any attack under the influence of the electric current. Sodium ferrocyanides does not interfere with anode corrosion in acid-copper solutions, except when free cyanide is low and the current density high. When sodium cyanide is used, only a high quality should be considered. Ammonium chloride should not be used in acid-copper solutions. WHB(7a)

Protective Value of Some Electro-Deposited Coatings. L. DAVIES & L. WRIGHT. *Sheet Metal Industries*, Vol. 4, May 1930, pages 27–31; *Metal Industry* (London), Vol. 36, Apr. 11, 1930, pages 407–410.

The Electrolytic Zinc Plant of the Evans-Wallower Company at East St. Louis, Ill. U. C. TAINTON & DANIEL BOSQUI. (The Evans-Wallower Zinc Co.) *Canadian Mining Journal*, Vol. 51, Aug. 28, 1930, pages 769–771.

See *Metals & Alloys*, Vol. 1, Oct. 1930, page 798. (7b)

Electrolysis of Molten Silver Lead Alloys. (Ueber die Schmelzflusselektrolyse von Silver-Blei-Legierungen.) ROBERT KREMANN, BORIS KORTH & ESTHER INGE SCHWARZ. *Monatshefte für Chemie*, Vol. 56, July 1930, pages 16–25.

Contains 4 references. The alloy 35% Ag, 65% Pb was melted and poured into capillary tubes of refractory material and electrolyzed for 6 hours at current densities ranging from 7.64 to 18.11 amps./mm.^{2} Temperature of the alloy reaches 1000° C. After cooling the rod was cut into sections and the individual sections analyzed for Ag content. Ag tends to migrate toward the cathode and Pb toward the anode. With the lower current Ag ranged from 33.85% at anode end to 43.10% at cathode end. With highest current from 44.05% to 53.05%, the higher Ag content being due to some of the Pb volatilizing at the higher temperatures. CEM(7b)

Experiments on the Electrolysis of Bronzes with Silver Additions. (Versuche über die Elektrolyse von Bronzen mit Silberzusätzen.) ROBERT KREMANN & ESTHER INGE SCHWARZ. *Monatshefte für Chemie*, Vol. 56, July 1930, pages 26–34.

Contains 4 references. Bronze containing 29% Cu and 71% Sn with additions of 1.3 to 10.8% Ag was electrolyzed for 4 hours at 2.5 to 5 amps./mm.^{2} according to the process previously described. Cu and Ag tend to migrate to the cathode and Sn to the anode. Photomicrographs show the structure of different sections of the electrolyzed rods. CEM(7b)

Experiments on the Electrolysis of Bronzes with Lead Additions. (Versuche über die Elektrolyse von Bronzen mit Bleizusätzen.) ROBERT KREMANN & WALTER PIMETZ. *Monatshefte für Chemie*, Vol. 56, July 1930, pages 71–78.

Contains 2 references. Bronze containing 28% Cu, 49 to 69% Sn and 21.6 to 2.9% Pb was electrolyzed for 4 hours at 2.2 to 6 amps./mm.^{2} according to the process previously described. Cu tends to migrate to the cathode and Sn and Pb to the anode. Photomicrographs show the structure of different sections of the electrolyzed rods. CEM(7b)

METALLIC COATINGS OTHER THAN ELECTROPLATING (8)

Bending Conditions of Galvanizing. HEINZ BABLIK. *Iron Age*, Vol. 125, May 15, 1930, pages 1452–1454; May 22, pages 1528–1531.

Good bending qualities are important for galvanized sheets and wires. Experiments show that Zn on very small discontinuities can afford a protection when there is an electrolyte of very good conductivity. This is true only when two conditions exist. First that the discontinuity is very small and second that Zn coating is thick. Rust protection is given only when a compact layer of pure Zn covers the iron base. Gives results of other investigators. Galvanizing coating should not break nor peel off under bending conditions. Lengthening of pure Zn layer is dependent on bending radius and thickness of sheet. Calculation shows that lengthening $\epsilon = h/2R$ becomes greater as sheet is thicker and bending radius smaller. Describes and illustrates formation of Zn and alloy layers. "Galv-annealing" is accomplished by placing a strong alloy between Zn layer and the Fe. Thick coatings versus thin coatings. If Fe-Zn alloy layer is small, bending quality is good, while if it exists to any noticeable degree bending is bad. Good bending can be secured by alloying Zn bath with Al. VSP(8)

The Testing of Zinc Coatings. *Metallurgist*, Sept. 1930, pages 131–132.

An extended abstract of the article by E. H. Schulz appearing in *Stahl und Eisen*, Vol. 29, July 17, 1930, pages 1017–1022. The paper is criticised on the basis of, after giving a very extensive comparison of tests, no correlation is made with service conditions and the real problem of serviceable accelerated testing has made no progress. See *Metals & Alloys*, Vol. 1, Nov. 1930, page 848. VVK(8)

Protective Coatings for Iron and Steel. I. Metallic Coatings. HENRY N. BASSETT. *Industrial Chemist*, Vol. 6, June 1930, pages 241–243.

This is a review containing much interesting information. In addition to protective coatings obtained by the processes of Barff, the Bowers, Gesner, Tatlock and Coslett are dealt with briefly. (8)

The Destructive Action of Molten Zinc, at and above Zincing (Galvanizing) Temperatures, upon Metals and Alloys. IX. The Action upon Tin, Lead, Cadmium, Arsenic and Antimony. WALLACE G. IMHOFF. *American Metal Market*, Vol. 37, Sept. 9, 1930, page 10. **X. The Action upon Aluminum, Magnesium, Cobalt, Platinum, Gold and Other Rare Metals.** Sept. 27, 1930, pages 5, 10; Oct. 1, 1930, page 10.

This discussion centers largely around the influence of the various soft metals in the galvanizing bath, their influence on the spangle, the alloys formed with zinc, and their influence upon the temperature of the bath, the fluidity of the bath and adherence of the zinc coating. Tin is used in the galvanizing bath to open up the spangle and give the sheet a bright, smooth finish. Conditions affecting the crystals are: (1) temperature of the zinc bath; (2) the submersion time; (3) the additions of metals to the bath (tin, etc.); (4) the time of cooling; (5) the iron content of the bath; (6) the quality and analysis of the steel base; (7) the smoothness of the surface, and (8) the pickling conditions. In the metalware industry the amount of tin added to the galvanizing bath is proportional to the surface area coated. Lead acts as a lubricant material, cadmium tends to lower the melting point of the bath and to make it thinner and more fluid. Used in the proper amounts with other alloying metals a very beautiful spangle can be developed. Little is known of the effects of arsenic and antimony though the latter in excess produces a yellow stain, and coatings peel and flake much easier than without it. Aluminum alloys readily with zinc, and any excess will come to the surface to form an undesirable scum. The chief function of aluminum in zinc baths is to keep down surface oxidation. Its amount is dependent upon the size of the kettle, the amount of material put through the bath, the bath temperature, the number of times the surface of the bath is skimmed when each article is withdrawn, the way it is put into the bath and the operator. Very little is known of the effect of magnesium on galvanizing baths, and cobalt dissolved in zinc to a slight extent. It might be sprayed on the inside of the galvanizing pots. WHB(8)

Copper-armored Steel "KPS" for Transmission Lines of Medium Voltage. (Kupferpanzerstahl "KPS" als Leitungsbaustoff in Mittelspannungsnetzen.) H. MARZAHL. *Elektrotechnische Zeitschrift*, Vol. 51, Oct. 2, 1930, pages 1395–1396.

This material consists of a steel core on which a copper cover is insolubly welded in vacuum. The copper is cast around a white-hot steel block. The ratio of the section of the two metals always remains the same in all the following rolling and drawing processes. The table gives comparative figures:

	KPS-wire	Copper wire
Weight in kg./cm.^{3}	8.22×10^{-3}	8.9×10^{-3}
Tensile strength in kg./mm.^{2}	65–70	40
Elasticity modulus, kg./mm.^{2}	15000	13000
Linear expansion coefficient for 1° C	1.35×10^{-5}	17×10^{-5}
Temperature coefficient for 1° C.	4.05×10^{-3}	3.7×10^{-3}
Specific conductivity at +20°C. in $\frac{m}{\text{Ohm mm}^2}$	19.5	55

Cost for installation and maintenance for KPS lines are lower than for copper under equal conditoins, and the safety against breaking is greater. Ha(8)

INDUSTRIAL USES AND APPLICATIONS (9)

Effects Large Savings by Chromium Plating Gages and Tools. *Iron Trade Review*, Vol. 86, Feb. 27, 1930, page 62.

From *Ford News*, Jan. 15, 1930. Ford Motor Co. has applied hard Cr plate to gages and machine parts resulting in important savings in time and costs. Plate gages formerly giving only 4 hrs. in certain grinding operations, now give 218 hrs., while a gage used on the small end of the connecting rod, could be used only 1300 times before plating. After plating this increased to more than 1800 holes. On tool fixtures, the parts show a saving of from 6–20 times after plating. Ms(9)

Principle and Uses of Wire Rope. Part VIII. WALTER A. SCOBLE. *Metallurgia*, Vol. 2, June 1930, pages 63–64; Sept. 1930, pages 183–184.

Lubrication of wire rope and causes of corrosion are discussed in detail. Graphite and similar opaque lubricants may cause excessive sliding of cables on traction-drive elevators and also interfering with the thorough inspection of the rope. Boiled linseed oil, applied hot, will saturate the hemp center, and will when dry, give a transparent covering. Corrosion may be due to the internal effect of incorrect preservative materials, or of excessive moisture in the fibre core. It is recommended that the fibre core be impregnated with lubricant by passing it through a bath containing a heated mixture of oil and petroleum jelly, as a protective against the subsequent absorption of moisture and as a reservoir for the lubrication of the internal wires and strands of the rope. The Conditions of Drop Forging, Overheating during Drop Forging, and Regeneration by Thermal Treatment of Cementation Nickel-Chrome Steel. (Le conditions de matriçage, la surchauffe positive au cours de matriçage et la régénération par traitement thermique de l'acier nickel-chrome de cémentation.) E. DECHERF. *Aciers Speciaux, Métaux et Alliages*, Vol. 4, Nov. 1929, pages 527–543.

A complete discussion is given together with new data, sketches, and photomicrographs. (10)

Practical Heat-Treating in the Small Shop. ARTHUR MUMPER. *American Machinist*, Vol. 72, April 24, 1930, pages 699–700.

Oil-hardened alloy steel should be heated to about 1,375° F. and quenched in an acid bath, and immediately drawn in an oil or salt bath to the desired temperature. Steel should be pre-heated to about the temperature of the furnace. If put in while cold the rapid expansion usually causes distortion. Describes the construction of a hot plate which the writer has used for preheating as well as drawing. Non-shrinkable, oil hardening steels should often be drawn longer than may seem necessary. Too short drawing time means the risk of cracks or distortion developing in a short time. RHP(10)

Recrystallization. (Ueber die Rekristallisation.) G. TAMMANN. *Zeitschrift für Metallkunde*, Vol. 22, July 1930, pages 224–226.

A general discussion of Tammann's views upon recrystallization under hardening; the formation of recrystallization nuclei; intercrystallization material; grain boundary displacement; repeated recrystallization; influence of cooling velocity; variation in grain size in recrystallization metals. Case Hardening & Nitrogen Hardening (10c)

Accurate Case-hardening. H. SWAIN. *Metallurgia*, Vol. 2, Sept. 1930, pages 185–186.

General discussion of the case-hardening process, emphasizing the importance of the effect of tempering temperature in case-hardening steel as given in the following table:

Steel	Not Tempered	Diamond Hardness Number Tempered at 100° C.	150° C.	200° C.
A	970	970	890	825
B	970	940	890	800
C	768	768	735	687
D	825	825	768	735

GTM(10c)

Nitriding Steel. *American Machinist*, Vol. 72, May 1, 1930, page 741.

Steels best suited to nitriding are those containing 0.72 to 1.25% Al and 1.00 to 1.50% Cr, with 0.20% Mo. These are manufactured under the trade name "Nitralloy" in C contents ranging from 0.20 to 0.40%. Gives very briefly the history, process precautions, finishing, advantages and present uses of the nitriding process. RHP(10c)

Quenching (10d)

The Effect of the Rate of Cooling on Steel. J. M. ROBERTSON. *Chemical Age*, Vol. 23, July 5, 1930, Metallurgical Section, pages 1–2.

A general survey of the effect of the rate of cooling on the structure and constitution of steel, of which this is an extended abstract, is given in Paper No. 59 of the Safety in Mines Research Board (H. M. Stationery Office, 2s. net.) VVK(10d)

On the Influence of the Cooling Velocity on the Transformation Points, the Structure and the Atom Structure of Iron-Carbon Alloys. (Ueber den Einfluss der Abkühlungsgeschwindigkeit auf die Temperatur der Umwandlungen, das Gefüge und den Feinbau der Eisen-Kohlenstoff-Legierungen.) F. WEVER & N. ENGEL. *Mitteilungen Kaiser Wilhelm Institut für Eisenforschung*, Vol. 12 (1930) Report 150, pages 93–114; *Stahl und Eisen*, Vol. 50, Sept. 11, 1930, pages 1308–1311.

This investigation was undertaken to determine what changes take place in the Fe-C equilibrium diagram under gradually increased cooling conditions, i. e., the relation between thermal effects observed during the quenching of a steel and the phase limits of the Fe-C diagram should be elucidated. These effects were studied in straight C steels with only very small amounts of Si and Mn. Furthermore electrolytic Fe was examined, which had picked up small amounts of C during a re-melting. N. Engel designed a special apparatus for the quench tests. The temperature was measured by means of Pt-Pt Rh thermo-couples, which registered the reading on a Siemens and Halske cardiograph. Even for the highest cooling velocities used the time-temperature course was excellently registered. In order to increase the sensivitity of the method an arrangement was furthermore developed to register the cooling velocity-time curves of the quenched samples. The results are: The A_3 point is lowered in pure Fe with increasing cooling velocity, first rapidly, later gradually. For the highest cooling velocity employed, 10,000° C./sec., the transformation is lowered to about 580° C. and nearly wiped out. No other effects occur. In very low carbon steels (0.037%) another effect (point M) appears at about 440° C., for cooling velocities above 5300° C./sec., besides the lowered A_3 point. The effect at M increases in favor of A_3 by slightly increasing the cooling velocity, so that finally only the effect at M is observed. For C contents above 0.3% the A_3, A_2 and A_1 points can no longer be distinguished, even at small cooling velocities. These points appear as one effect after an undercooling effect (recalescence). At higher cooling rates M also appears. The effects in hyper-eutectoid steels are similar. Point M is lowered with increasing C content and increasingly loses its significance. In a 1.8% C steel point M is but faint at 120° C. The results on the thermal effects have been plotted in a concentration-temperature, cooling velocity diagram which is discussed in detail. The structures correspond to this diagram. The quenched samples of pure Fe contained always a 100% homogeneous, polyhedric structure. At sufficiently high cooling rates needles of martensite appear. With increasing C content the relation between thermal history and structure becomes more and more significant. As to the influence of the cooling rate on the atomic structure the following was stated: Interferences of a cubic space centered crystal are observed in samples up to 0.4% C. These interferences decrease with increasing C content and are shifted sidewise either way, which can be explained by the slowly appearing tetragonal distortion of the lattice. At 0.9% C, the split of the cubic lines into tetragonal doublets is already significant. The axial ratio increases with the C content. It is 1.034 for 0.97 C and 1.062 for 1.8% C. The change of the axial ratio with increasing cooling velocity is but slight. The lines of the cubic face-centered austenite can be observed from 0.6% C on. They become more pronounced with increasing C content and increasing cooling rate. The results of the structure analysis in connection with the thermal investigation, therefore, lead to the clear proof that point M corresponds to the appearance of a new tetragonal crystal. The opinion held formerly that the transformation is nothing other but a retarded pearlite transformation must be revised. The transformation M is practically independent of the cooling velocity, the transformation occurs very quickly with a pronounced heat effect. GN(10d)

Drawing (10e)

Drawing of Severely Quenched Alloy Steels. (Etude sur les revenues d'aciers speciaux hypertrempes.) ANDRE MICHEL & PIERRE BENAZET. *Revue de Metallurgie*, Vol. 27, Sept. 1930, pages 501–508.

When steels quenched from temperatures much higher than their critical points are drawn either a sudden very sharp dilatation corresponding to γ-α transformation of the metal or a gradual precipitation of the carbides subsequently followed by γ-α transformation can be observed. By heating under the transformation temperatures the steels belonging to the first class can be made to show gradual precipitation of the carbides. The present investigation was directed toward determination of the influence of alloy additions on behavior in drawing. Several C-Cr steels were investigated to determine temperature of complete austenization and the reactions on drawing. With 1.0 C and 6.0 Cr it is complete at 1250° C. and on drawing precipitation of carbides occurs at 530° C. and a violent transformation of γ into α at 580° C. Heating at 550° C. causes on cooling precipitation of carbides (gradual) and lowers γ-α transformation to about 150° C. With 16 Cr the transformation on straight heating is raised to 630° C. Using 0.6 C, 15 Cr one has to raise quenching temperature to 1250° C. while on cooling only a gradual precipitation of carbides can be obtained and no γ-α transformation. With the same C but 19 Cr precipitation of carbides is not completed after 17 hours at 600° C. but on cooling slight transformation takes place at 300° C. which is not present in the lower Cr steel. The carbides precipitated are not strictly double carbides but a product of replacement of Cr with Fe atoms. Presence of 5% W facilitates austenization of 5% Cr steel, but handicaps it with 10% Cr. In the first case heating to about 600° C. causes a sharp transformation to occur while γ-α change is lowered to about 100° C. With higher Cr heating at 680° C, precipitates carbides but no transformations take place on cooling. In Cr steels 10% Co appears to interfere with the austenization and helps in decomposition of austenite on drawing, but in amounts around 20% it has an opposite effect. JDG(10e)

Tempering of Mild Steels Containing Copper. *Metallurgist*, June 1930, pages 87–91.

A detailed review of the work of F. Nehl, *Stahl und Eisen*, Vol. 50, May 15, 1930, page 678 and of H. Buchholtz and W. Köster in *Stahl und Eisen*, Vol. 50, May 15, 1930, page 687. See *Metals & Alloys*, Vol. 1, Oct. 1930, page 792 and 800 VVK(10e)

Heat Treatment of Soft Steel. (Il Trattamento termico dell'acciaio extradolce.) G. SIROVICH. *La Metallurgia Italiana*, Vol. 8, May 1930, pages 555–560.

The author states that the mechanical properties of mild steels as well as higher C steels depend on the drawing temperature, such as is used from 400–900° C. With increase in drawing temperature, elastic limit and tensile strength decrease while ductility gradually increases. This investigation, which was carried out at the Royal School of Engineering in Rome, Italy, shows that soft steel can be drawn and can exhibit special good properties after a proper heat treatment. Tables and diagrams are given showing the effect of drawing temperature on the mechanical properties. GTM(10e)

Aging (10f)

The Effect of Aging on the Behavior of Steels Subjected to Repeated Stresses. (Einfluss des Alterns auf das Verhalten weichen Stahles bei Schwingungsbeanspruchungen.) KARL ADERS. *Mitteilungen Forschungs-Institut Vereinigte Stahlwerke Aktiengesellschaft, Dortmund*, Vol. 1, No. 8 (1929) pages 201–221, 30 references.

Two steels having 0.07–0.08% C, 0.44–0.48% Mn, 0.01–0.05% Si, were tested and the results obtained showed that while the endurance is increased beyond the limit, the elastic limit is also increased. It was also noted that the whole structure exhibited a great number of gliding planes which were due to the repeated stresses. GTM(10f)

Age-Hardening. *Metallurgist*, June 1930, pages 81–82.

An historical discussion. VVK(10f)

On the Age-Hardening Mechanism in Al-Cu Alloys. S. KOKUBO *Kinzoku no Kenkyu*, July 1930, pages 343–370.

Al-Cu alloys containing 0 to 12% Cu were heated for 30 min. at 545° C and then quenched in water at 15° C. After aging for 10 to 20 days at room temperature, each of these specimens was heated for 6 hours at different temperatures up to 500°; they were then cooled slowly in furnace. Their density, electric resistance, hardness and thermal change were measured. The results do not agree with the conclusions of the precipitation theory of Merica and others. The results are represented in Fig. 1 in which the thermal change is shown in the electromotive force produced in the differential thermocouple. Density shows a minimum point at 270° C. Electric resistance begins to decrease abruptly at 150° C. Hardness shows a maximum at 170° C. The thermal change shows a minimum at 150° C., i. e., an absorption of heat; and a maximum at 260° and at 370° C., i. e., an evolution of heat. According to the precipitation theory, hardness increases with the precipitation of $CuAl_2$ and also with the increase in the size of $CuAl_2$ up to the critical size as shown in curve C; but this must be necessarily accompanied with heat evolution, in fact heat absorption is found. The author considers that in aging at 0–170° C. some copper atoms displace Al atoms in Al-space lattice; some Al atoms rotate by an angle 45° in the same plane; the Al-space lattice extends in the direction, [011] and contracts in the direction [011]. As the atomic volume of aluminum is larger than that of copper, there must occur great stresses in the space lattice of the metal. The results of these phenomena are the great increase in hardness, the absorption of heat and the small change of specific gravity and electric resistance. At the temperature 170–270° C. the precipitation of $CuAl_2$ takes place vividly and the result is the great evolution of heat and abrupt decrease of hardness, electric resistance and specific gravity. Above 270° C., the precipitated $CuAl_2$ gradually coagulates and forms its own space lattice. This means the decrease of potential energy and must be accompanied by heat evolution as shown in the figure (heat evolution at 370° C.). KT(10f)

JOINING OF METALS & ALLOYS (11)

Brazing (11a)

Phosphor-Copper for Welding and Brazing. C. J. SNYDER. (Westinghouse Electric & Manufacturing Co.) *American Machinist*, Vol. 72, May 15, 1930, pages 793–795.

Phosphorus and copper make useful alloys when the phosphorous content is less than 15%. With an 8% phosphorous content, a eutectic of the compound Cu_3P and a solid solution of phosphorus is formed with a melting point of 707° C. This eutectic makes possible the use of these alloys for brazing. It is very fluid and has unusual welding, penetrating and flowing properties. Two alloys are suitable for practically all kinds of work, one contains from 6½% to 7½% of phosphorus and the other from 4½ to 5½%. The best temperature is from 750 to 825° C. Phosphorus being chemically active, reduces oxides on the surface of the metal and acts as a flux and cleaning agent. Because of the high temperatures necessary for brazing, the yield point of the parent metal adjacent to the joint will be approximately 4000, 12,000 and 18,000 lb./in.² for copper, brass and bronze respectively. A butt joint in copper bars brazed with phosphor-copper alloy will break between 18,000 and 32,000 lb./in.² Lap joints tested on a shear test will withstand from 12,000 to 19,000 lb./in.² depending on the material and method of brazing. RHP(11a)

Molybdenum-Wound Hydrogen Furnaces for Copper Brazing. C. M. THOMPSON. *Iron & Steel Engnieer*, Vol. 7, Sept. 1930, pages 471–473.

A square box-type furnace developed by the General Electric Co. has been constructed for the manufacture of Carboloy tipped circular saws. The heating chamber is 36″ × 6″ × 4″ with molybdenum wire heating elements mounted on each side and above the chamber 18″ long. The units are wound on alundum tile and are exposed. The hearth tile is of channel cross section, and vertical sliding door is at the front of the furnace. At the opposite end is a cooling chamber 24″ long, and between the heating and cooling chambers, there is an airtight gate valve protected from the high temperatures by a tile slide. Hydrogen is fed from the top and discharged through a peep hole in the charging door and a pilot under the discharge door of the cooling chamber. Hydrogen consumption is 10–12 ft.³/hour and the furnace will handle 25 lbs. of material/hour. WHB(11a)

The Effect of Contamination by Nitrogen on the Structure of Electric Welds. L. W. SCHUSTER. (British Engine, Boiler & Electrical Insurance Co.) *Iron & Steel Institute, Advance Copy* No. 8, Sept. 1930, 30 pages.

Contains bibliography of 50 references. Microscopic examination of arc welds made from various rods and in atmospheres of air, carbon dioxide, oxygen, nitrogen and hydrogen have shown that the needles found in welds are caused by nitrogen. Needles never occur in the absence of nitrogen. A heat treatment is frequently necessary to develop the needles. Typical photomicrographs are shown. JLG(11c)

Arc Welding in Industry. H. M. FRENCH. (General Electric Co.) *Mining & Metallurgy*, Vol. 11, July 1930, page 352.

Describes the various kinds of arc welding namely: Metallic arc, the carbon arc, atomic hydrogen arc and shielded arc methods. Gives advantages of arc welding structural steel building over riveting. Arc welded joints in pipe lines are favored. Atomic hydrogen arc successful on very thin stock. VSP(11c)

Recent Welded Bridges. (Neuere geschweisste Brücken.) R. BERNHARD. *Zetischrift Verein deutscher Ingenieure*, Vol. 74, Aug. 30, 1930, pages 1201–1207.

Three bridges built in 1929 are described. The principles of construction, static design and shop work, especially details deviating from usual practice, are described. It is emphasized that great care and attention must be paid to the tension due to welding and that the design has to be adapted to welded joints which differs from that of riveted joints. Under such conditions, bridges can be built more economically with the welding method. Ha(11c)

First Arc-Welded Pipe Line Goes into Republic of Mexico. *Iron Trade Review*, Vol. 86, Feb. 6, 1930, pages 84–85.

Describes construction of a natural gas pipe-line 165 miles long, running from Aquilares, Texas to Monterey, Mexico. It is of 12-inch pipe. MS(11c)

Testing Steel Sheet for Weldability. *American Machinist*, Vol. 72, May 15, 1930, page 790.

Impurities in steel affect weldability of steel. To test take a piece of sheet about 6 in. square and place flat on welding table. Use a tip on the oxyacetylene blow torch which is a size smaller than that prescribed on the welding chart. Light and adjust flame to neutral. Hold the blowpipe so that the tip of the inner cone of the flame is about one eighth inch from the sheet. Move the flame slowly in a straight line so that the sheet is melted without burning clear through. After a strip of about 3 in. in length is melted in this way the blow pipe is held still until a hole is burned through the sheet. The path followed by the blowpipe should be free from an excess of oxide or scale and be regular and smooth on the upper side. The under side will show a slight sag of smooth metal, free from oxide. The hole should be round and regular. RHP(11c)

Procedure Control in Welding. H. W. GILLETT. *Metals & Alloys*, Vol. 1, July 1930, page 612.

A note recommending attention to development of machine welding. A suggestion is made relative to the hazard of the personal equation. ESC(11c)

Study of High-Manganese Slags in Relation to the Treatment of Low-Grade Manganiferous Ores. C. H. HERTY, JR., J. A. CONLEY & M. B. BOYER. *Report of Investigations* 3048, *United States Bureau of Mines*, Oct. 1930, 4 pages.

A tentative equilibrium diagram for the ternary system FeO-MnO-SiO_2 is proposed. The general shape of the liquids in the high manganese oxide corner is of a gradually descending slope from the melting point of pure manganese oxide down to the center of the diagram. The first break in the MnO–SiO_2 binary system occurs at or near the melting point of tephroite ($2MnO.SiO_2$). A boundary line extends from this point into the system and separates from the rest of the diagram the region of high manganese oxide in which manganese oxide doubtless exists as the solid phase in the liquid resulting from the decomposition of tephroite. This perhaps explains the high viscosity of the high manganese slags. Addition of 12 to 14% of alumina to such slags reduces the viscosity to a point where they can be handled. Tests showed that these high alumina slags can be reduced to ferro-manganese as satisfactorily as the low-alumina product. (Includes 4 footnote references.) AHE(12a)

Alloy Steel Guns Cast Centrifugally with Mounts of Welded Parts. T. C. DICKSON. *Iron Age*, Vol. 125, May 22, 1930, pages 1521–1522.

Taken from a paper read before the Cleveland Engineering Society, May 13, 1930. The feature of centrifugal casting is that the C content of the inner bore is higher than the outside. Impurities collect on the inside and are easily removed. The next step is the hydraulic cold working treatment The advantages of this process are that more guns can be made in less time and at less cost. The gun carriages are made of welded structures. Mo-steel is used because it is the best alloy possible for severe requirements. The largest gun made by the centrifugal process weighed about 800 lb. VSP(12b)

Designing Ingot Molds to Reduce Losses. EMIL GATHMANN. *Blast Furnace & Steel Plant*, Vol. 18, Jan., 1930, pages 119–121; *Iron Trade Review*, Vol. 86, Jan. 9, 1930, pages 25–27; *Rolling Mill Journal*, Vol. 3, Dec. 1929, pages 505–509.

Outlines factors which govern the design of ingot molds and discusses the cross-sections of various molds. Two, recently patented by the author, embody what he considers proper features for good surface in both big-end-up and big-end-down practice. The lines connecting the corners of the mold matrix are so corrugated as to offer no obstruction to free contraction of the metal toward the neutral lines of shrinkage. Corrugation of the secondary corners results in a flexible ingot surface. The corners are broad and are not apt to be burned in reheating or lapped in rolling. The projecting primary sides are spread in a direction approximately tangent with the axis of the rolls in the initial passes rather than flowed longitudinally, as is the case when the primary sides are wide and in substantially the same plane as the corners. The free, unworked adjacent sides are thus not elongated and are deformed only slightly. MS(12b)

Modern Zinc Base Die Casting. W. M. PIERCE. *Metals & Alloys*, Vol. 1, June 1930, pages 544–546.

Die casting requires an alloy which will not be contaminated by being retained in an iron pot in the molten state. High fluidity is needed for soundness and smooth finish. It must cast free from shrinkage strains. Zinc alloys containing 3–15% aluminum or 5–10% tin have been found satisfactory. Present practice utilizes a composition 1% aluminum, 3% copper, and frequently 0.1% magnesium. Less than 1% aluminum enters into solid solution with zinc to form an alloy known as the α-phase, zinc in aluminum up to 20% yields γ-phase alloy. Between 1–21% aluminum in zinc a eutectic of α-phase and β phase occurs with excess of α when aluminum content is less than 5% and excess of β when aluminum is above 5%. At 270° β is transformed to α and γ with increase in volume and evolution of heat. In pure zinc aluminum alloys the rapidity of this change causes stresses. Copper, magnesium and nickel aid materially in eliminating this factor. Early zinc alloys used for die casting showed inter-crystalline corrosion even before corrosion of surface grains. With copper containing alloys this factor may be almost completely eliminated. Heat treatment is useful in some cases. ESC(12b)

Rolling (12c)

Rolling of Aluminum Structural Shapes at the Massena Plant of the United States Aluminum Co. W. F. Boericke. *Mining & Metallurgy*, Vol. 11, April 1930, pages 222–223.

Discusses recent completion of a $4,000,000 addition to its plant, consisting of a larger blooming mill, and structural mill. Gives its organization, the distinction of possessing largest Al rolling mill in the world, as well as the first mill to roll Al exclusively. VSP(12c)

Tin and Sheet-Mill Rolls. Their Treatment, Performance and Premature Failure in Service. Eric R. Mort. *Engineer*, Vol. 149, May 16, 1930, pages 537–538; *Engineering*, Vol. 129, May 9, 1930, pages 615–617; *Foundry Trade Journal*, Vol, 42, May 22, 1930, pages 377–378, 387–388; *Iron & Coal Trades Review*, Vol, 120, May 2, 1930, pages 712–714.

Sheet Steel and Blackplate Manufacture. John Mort. *Blast Furnace & Steel Plant*, Vol. 17, Dec. 1929, pages 1816–1822.

From a paper before the Swansea Technical College Metallurgical Society. Discusses design of bar and reheating furnaces. The basic factors are capacity, the temperature to which steel is to be raised and the fuel to be used. In addition, for reheating furnaces, the temperature at which the partly-rolled sheets are returned for reheating, and the sheet dimension must be considered. The rate of heating depends chiefly on the heat input and the design of the chamber. Chilled iron rolls are used. The principal factors which determine roll contour are: "Character of chill," roll dimensions; class of sheets to be rolled; temperature at which the rolls are to be maintained when in commission; method of contour control; and mill production. Uniformity of gage depends on uniform heating of bars and packs, roll contour and correct drafting. Discusses rather fully roll turning. Presents charts showing the fluctuations in roll temperature that occasionally take place under normal working conditions. MS(12c)

Investigations on the Production Capacity and Power Consumption in Rolling Different Steel Shapes. (Untersuchungen zur Feststellung der Leistungsfähigkeit und des Kraftverbrauches für verschiedene Walzprofile.) G. Bulle, C. N. Elsen & A. Knickenberg. *Stahl und Eisen*, Vol. 50, Aug. 7, 1930, pages 1121–1126, 4 references.

Report No. 76 of the Rolling Mill Committee of the Verein deutsche Eisenhüttenleute. Time and power consumption of various shapes were studied in 5 different rolling mills, namely a loop mill, a merchant mill for fine shapes, 2 bar mills and a rod mill to determine how the production cost changes with the dimensions of similar shapes and to find out the best economical conditions for running the mill. The power consumption for the actual deformation work in rolling (that means the values for power consumption when the mill is running light are deducted) is in simple relation to the shape size for rounds, flats, hoops, angles, tees and mining rails. The actual power consumption increases with decreasing diameter of rods and round bars and increasing thickness and width of flats, hoops, etc. The actual power consumption for hoops, flats and other small shapes is approximately the same, provided height of flange and thickness are the same. Capacity index cards are designed for power consumption and rolling time per ton of material rolled for the shapes investigated. By means of these capacity curves power consumption and production conditions for shapes never rolled before can be predetermined and different rolling mills can be compared as regards their efficiency. Investigations like this one open a field for improvement of production methods in rolling mills. GN(12c)

Sheet and Tinplate Rolls. An Investigation into the Roll Loads, Stresses and the Causes of Roll Breakage. J. Selwyn Caswell (University College, Swansea). *Proceedings South Wales Institute of Engineers*, Vol. 46, Aug. 22, 1930, pages 311–452; *Iron & Coal Trades Review*, Vol. 121, Aug. 15, 1930, pages 217-218.

After discussing the manufacture of sheet and tinplate rolls, the author presents data gathered over a year's time in 29 sheet and 28 tinplate mills on roll breakage, temperature variations in the mills, loads carried by sheet and tinplate rolls, torsional loads, physical properties of gray and chilled roll iron, the magnitude and variation of the stresses in the rolls [set up (1) in the foundry, (2) by the mill loads, (3) by thermal strains and (4) by other causes] and hair-cracks and firemarks on the faces of fracture. The ratio of number of rolls broken annually to number of mills is approximately 1.8 for tinplate and 4.0 for sheet mills. Average life of rolls is 16 weeks and 8 weeks for tinplate and sheet mill rolls, respectively. In tinplate mills life depends chiefly on the life of the chill in sheet mills on breakage. Greatest breakage is in winter. 82% broke through the body. Breakage is more frequent with large diameter rolls. Maximum loads in tinplate roughing mill = 500 tons, in finishing mill = 420 tons and in sheet mill = 1140 tons. Maximum torque is approximately 17,000 in.-tons. RPH+AHE(12c)

The Influence of the Lateral Pressure on Deformation during the Rolling Process and the Quality of the Material. (Der Einfluss des Seitendruckes auf die Formänderung beim Walzen und die Güte des Werkstoffs.) H. Hilterhaus. *Stahl und Eisen*, Vol. 50, Aug. 21, 1930, pages 1185–1194; Aug. 28, 1930, pages 1221–1229. Dr.-Ing. Thesis, Aachen, 1929.

After outlining the theories on the flow of material during rolling, the author submits the results of his investigations on a three-high mill. Results show that lateral pressure in the pass is practically vertical pressure. This opinion is proved by metallographic examinations and studies on the power consumption. Due to a decreased spread by vertical pressure, the upper section of the beams are not filled. Tests were carried out which explain the relations between underfilling and pressure, and the flange sections which receive no pressure during the process of deformation. Calculations check the practical results. GN(12c)

Strip Rolling Mills. W. W. Robertson. *Metallurgia*, Vol. 2, May 1930, pages 4–6.

General discussion of both hot and cold strip mills. Roller bearings can be used to advantage on hot mills and light type cold mills, but not with entire success on heavy type cold mills due to the necessary reduction in neck diameter. The new "flood" type bearing in which the oil is forced through the bearing under low pressure is successful. Maximum speeds of 300 feet per minute have been obtained with these bearings. Backed-up-type of mills are finding considerable application. Steel rolls are replacing chilled iron rolls. For hot rolling a not dead-hard steel is used and for cold rolling a chromium steel hardened to 100 Scleroscope is recommended. Backing rolls should be softer than the working rolls. The four-high mill has made possible the production of steel strip 36 inches wide. JLG(12c)

Forging (12d)

Construction of Drop Forging Dies. George A. Smart. *Heating Treating & Forging*, Vol. 15, July 1929, pages 841–842; Aug. 1929, pages 1004–1006; Sept. 1929, pages 1169–1171, 1175; Oct. 1929, pages 1293–1295; Nov. 1929, pages 1429–1432; Dec. 1929, pages 1564–1566; Vol. 16, Jan. 1930, pages 59–61, 63; Feb. 1930, pages 185–187; March 1930, pages 324–327; April 1930, pages 462–465; June 1930, pages 735–737, 742; Sept. 1930, pages 1147–1151; Oct. 1930, pages 1269–1272.

Parts XII–XIII are entitled "Dies for Bulldozing and Upsetting." Outlines general considerations in selecting the type of forging due to suit conditions in producing a given forging. Discusses layout of the die proper, blockers, fullers, rollers, cutoffs, dowells, snakers, locks, counter-locks, radii and fillets, templets, types, trimmers and punches, manufacture of miscellaneous forgings and forming and bending in bulldozers. MS(12d)

Shearing & Punching (12e)

Cutting and Punching of Metals. (Schneiden und Lochen von Metallen.) E. Siebel. *Stahl und Eisen*, Vol. 50, Aug. 14, 1930, pages 1172–1173.

E. Siebel reviews a paper by Ch. Frémont in Bulletin de la Société de l'-Encouragement pour l'Industrie Nationale, Vol. 128 (1929) pages 563–673, in which this author summarizes his ideas on cutting and punching. Frémont takes the standpoint that cutting and punching is not a pure shearing process, that the stresses are principally tensile stresses. To investigate the problem special methods were developed, which permit studying the deformation by observing the formation of gliding planes on polished samples. In cutting tests no relation could be established between tensile strength T and shear resistance C. For carbon steel, however, the relation $C = (T \times .35) + 6.5$ kg./mm.^{2} is correct. In punching tests with various steels the relation C:T = 0.71 to 0.75 was found. The influence of friction is relatively small for simple cutting; friction has a much heavier influence on the stamping process. Frémont furthermore shows how the punched section can be used for investigating the material. Metallographic static and dynamic bending tests are proposed. The author finally deals with the change of material and the effect of aging which takes place in the material around the punched holes. GN(12e)

Machining (12g)

Power Required to Drill Cast Iron and Steel. O. W. Boston & C. J. Oxford. *Transactions American Society Mechanical Engineers, Machine Shop Practice*, Vol. 52, Jan.-Apr. 1930, pages 5–26.

11 references. This paper presents the results of drilling tests on cast iron and steel. Drills ranging in diameter from $^1/_2$ to $1^1/_2$ in. of the standard twist-drill type were used. The drills were considered sharp in all tests. A coolant consisting of one part of soluble oil and 16 parts of water was used in all tests. The materials cut consisted of one regular machining cast iron and one cast iron made up of 20 percent charcoal pig iron, together with 17 steels of a wide variety of chemical analyses, which were selected to cover the steels commonly used in modern manufacture. Data as to drilling torque, thrust, computed horsepower at the drill point and net horsepower supplied to the machine as measured on a recording wattmeter are given under two headings: commercial tests and special tests. All commercial tests were run at a peripheral speed of the drill of approximately 60 ft. per min. The feed for each drill size was as near to those given in the usual commercial-drilling table as the change gears available would permit. Special tests were run on various cast irons and steels so that the influence of the speed feed, and drill diameter could be determined, in order that the results of the commercial-drilling tests could be extended to cover any other conditions of drilling for each material. It was found from these special tests that the thrust for both cast iron and steel increased in direct proportion to the drill diameter d; that the torque increased in proportion to d^2 for cast iron and $d^{1.8}$ for steel. The thrust increased with an increase in feed f, but at a rate as slow as $f^{0.6}$ for both cast iron and steel. The torque increased as $f^{0.6}$ for cast iron, but $f^{0.78}$ for steel. It was found that the torque and thrust remained practically constant over the whole range of speeds covered from 74 to 441 r. p. m. for each drill size and feed. An attempt made to correlate the hardness values of the materials determined by various hardness testers with the results obtained from the drilling tests showed that no satisfactory relation exists between these properties. (12g)

Test Code for High-Speed Steel for Turning Tools. *Advance Paper* No. 49, *American Society of Mechanical Engineers*, Dec. 2–6, 1929, 3 pages.

A report of Sub-Committee "D" on Properties of Materials of A. S. M. E. Special Research Committee on Cutting of Metals is given. An outline is given of the A. S. M. E. tentative test code for high-speed tool steel intended for the manufacture of lathe and planer tools; grinding; heat treatment; test forging; test cut; and work done by cutting tools. (12g)

Square Turning Alloy-Steel Ingots. *Metallurgia*, Vol. 2, June 1930, pages 65–66.

A lathe produced by H. A. Waldrich, Siegen, for removing the surface of a square ingot is described. Two or three tools can be used on each lathe at the same time. The square turning of ingots 44 inches long and 10 or 11 inches square takes only 40 to 48 minutes, including setting up and taking down. JLG(12g)

Tungsten Carbide Cutting Tools in America. *Metallurgist*, Vol. 5, Aug. 1929, pages 114–115.

The results are given of hardness tests of tungsten-carbide alloy with 6% cobalt and water-toughened manganese steel. (12g)

More Chips from Tungsten-Carbide Tools. Frank W. Curtis. *American Machinist*, Vol. 72, April 10, 1930, pages 608–611.

Tungsten-carbide tools should be ground as often as the tool steel previously used. To secure the proper service the speed and the feed should be increased. This often requires larger and heavier tools. Too wide or too long tips are to be avoided. The success of any metal cutting operation depends on rigidity so it is better to use a heavier tool than actually necessary. RHP(12g)

More Chips from Tungsten-Carbide Tools, Discussion. Chester B. Lord. (American Machinist.) *American Machinist*, Vol. 72, June 19, 1930, pages 985–986.

Discusses some parts of the article of the same title by Frank W. Curtis, *American Machinist*, Vol. 72, April 10, 1930, pages 608–611. There are many exceptions to the statement that the "ideal application is one in which the tool is ground as often as the steel tool previously used." Increase in machine size is not always economical and does not always produce the desired result. More information concerning cutting by tungsten-carbide is needed before some of the claims for it can be substantiated. RHP(12g)

Grinding Tungsten-Carbide Tools. *American Machinist*, Vol. 72, April 17, 1930, page 669.

Cemented tungsten-carbide can only be formed and finished by grinding, honing or lapping. Since it is costly only small amounts should be removed per grind. It should not be crowded against the grinding wheel. It may be ground either wet or dry. If dry, periodical cooling of the tool shank is necessary. It must not be quenched or the tip will check and crack. More rapid work is possible in wet grinding but for small jobs dry grinding is recommended. Either a diamond or a dresser, preferably the latter should be used in dressing. The diamond dresser tends to dull the abrasive, but is necessary if the wheel is to be formed. Roughing of tungsten-carbide tools should be done on a 60- or 80-grain wheel, finishing on a 100- to 120-grain wheel. Wheel speed of 4000 to 6000 is recommended. Illustrates methods of grinding special types of tools. Briefly discusses the lapping process and the cutting mixture used. RHP(12g)

Factors Affecting Machinability of Malleable Cast Iron. H. A. Schwartz. (National Malleable & Steel Castings Co.) *American Machinist*, Vol. 72, May 29, 1930, pages 871–873.

Data is given on a series of tests to determine the effect of carbon content on the machinability of malleable iron. The range of carbon content tested was from 2 to 3.10%. Tests used were drill, turning and threading tests. The data is not sufficient for very definite conclusions but indicate that carbon does affect machinability. The higher carbon is more easily machined. RHP(12g)

Drawing & Stamping (12h)

Application of Compressed Air Crimping Holders to the Working of Non-Ferrous Metals. (Verwendung von Druckluft-Faltenhaltern bei Verarbeitung von Nichteisenmetallen.) O. KÜHNER. *Zeitschrift für Metallkunde*, Vol. 22, June 1930, pages 190–193.

Paper deals with deep drawing of non-ferrous metals. Experience with commercial types of crimping or plate holders is given and a new device fully described which allows deep drawing of thin plates without rupture. By utilization of the maximum of drawing capacity intermediate annealing or some steps in the mechanical part of the drawing operation are rendered superfluous. The time required for placing the sheets into the machine is furthermore cut down. EF(12h)

Pickling (12i)

Treatment of Metals with Acids. (Die Behandlung der Metalle mit Säuren.) *Deutsche Goldschmiede-Zeitung*, Vol. 33, March 22, 1930, pages 136–137.

A general discussion of the use of acid solutions in metal working with particular reference to precious metals and their alloys. Discusses use in pickling, etching, coloring and dissolving JLG(12i)

Pickling Principles in Galvanizing. W. G. IMHOFF. *Iron Age*, Vol. 126, July 10, 1930, pages 82–83, 131.

Pickling time depends upon the temperature of the pickel. Varying the % of acid, operation may be speeded up or slowed down within wide limits. By controlling the temperature of pickling bath and installing standard conditions of pickling, direct saving of acid, steam, labor and time will result. "Acid brittleness" is of great importance in pickling wire. Proper pickling conditions should be a 4 to 5% acidity, temperature not over 170° F. and pickling time of 20 min. Gives views of practical men. VSP(12i)

The Pickling and Cleaning of Metals. I. Some Considerations of the Chemical Reactions Involved. DAVID BROWNLIE. *Sheet Metal Industries*, Vol. 4, Sept. 1930, pages 347–349.

The author discusses the acids used for pickling, namely, sulphuric, hydrochloric, hydrofluoric in rare cases, and nitric acid. The fundamental chemical equations involved are brought out. The effect of purity of the metal, purity of the acid, and the presence of moisture are considered. AWM(12i)

Cold Working (12j)

Texture of Cold Deformed Metals. (Texturen kaltverformter Metalle.) F. WEVER & W. E. SCHMID. *Zeitschrift für Metallkunde*, Vol. 22, April 1930, pages 133–140, 39 references.

A study was made to investigate the flow of metals and the resultant structure after cold deformation. A special device was applied by the authors allowing the metal to flow only in one direction perpendicular to the direction of compression. Parallelopipeds of Al—as a face centered cubic representative—and of Fe belonging to the group of body centered metals were compressed in various steps in the specially designed press and then studied for preferred orientation by means of X-rays according to the Debeye-Scherrer method. The laws of plastic deformation of cubic face centered single crystals are employed to interpret the resultant textures. The mechanism of plastic crystal warping is stressed. For the higher degrees of deformation pole-figures were obtained. The texture of Al submitted to parallellopiped deformation is established to be a superimposing of parts of the texture in case of axial-symmetric elongation or compression with the axes in the direction of flowing and compression respectively of the plane deformation process. The deviations of the experimentally determined atom planes from those derived from theoretical calculations are investigated in Al after various steps of deformation and are explained with the help of deformation and strain hardening processes observed in single crystals. The observations from the face centered cubic metal are converted to the body centered cubic arrangement under the presumption that the mechanism of deformation takes place along (011) as the gliding plane and in (111) as gliding direction. Since the parallelopiped deformation is closely related to the process of rolling as it is proved by the analogy of both textures, the authors arrive at a comprehensive representation of the most essential deformation textures based on the known deformation mechanism of single crystals. EF(12j)

Limit of Hardness for Certain Metals for Coins. *American Metal Market*, Vol. 37, Aug. 7, 1930, page 5.

The results of the experiments of three Frenchmen have been published by the Academie des Sciences, Paris. Experiments covered the limit of hardness obtainable with certain metals for making coins and medals by stamping. The compression obtained by cold treatment is the determining factor as regards hardness, and though the degree of hardness rises rapidly at the beginning of the compression, the limit appears to be obtained, with all metals and alloys investigated, when the thickness has been reduced by about 80% of the original dimension. With a reduction of about 76% nickel, and also a copper alloy with 8.8% aluminum showed the greatest degree of hardness. These were followed by a bronze with 94% copper, 4.6% tin and 1.4% zinc and by gold 90% pure. WHB(12j)

Preferred Orientation in Silver Foil Produced by Cold Rolling. CLEVELAND B. HOLLABAUGH. *Metals & Alloys*, Vol. 1, July 1930, pages 602–606.

According to earlier data, cold rolling of metals having a face centered cubic crystal structure causes one definite orientation, independent of the rolling technique. Aluminum and zinc show two possible orientations indicating a dependence upon the type of deformation. A study of the latter is conducted in this paper. Apparatus for X-ray patterns by the pinhole method and diffraction method were used. The sample was "fine" bar silver. Sample was annealed at 750°, 850°, 900° C. studying the orientation at intervals by both methods. The latter yields a completely random arrangement. A series of samples of various thicknesses were used. Two diffraction patterns were made of each. Technique of interpretation of patterns and data is completely explained. It is found that the mechanical working of silver produces two preferred orientations of crystals. The degree of preferment of each has been found. These preferred orientations are not affected by either the % reduction per pass nor the absolute reduction per pass through the rolls. ESC(12j)

Modern Practice in the Cold Rolling of Non-Ferrous Metals. C. E. DAVIES. *Metallurgia*, Vol. 2, Aug. 1930, pages 145–146.

Discusses methods and equipment used in rolling copper and its alloys. JLG(12j)

Cleaning (12k)

Metal De-greasing Plants with Tri-Chlor-Ethylene. (Metall-Entfettungsanlagen mit Trichloräthylen.) MAX HELLER. *Zeitschrift Verein deutscher Ingenieure*, Vol. 74, July 26, 1930, pages 1069–1070.

For freeing large quantities of metal parts of oil, grease, etc., the non-inflammable and non-explosive tri-chlor-ethylene finds more and more use but it requires special equipment as the vapors are health-impairing. Several open and closed plants are described; the liquid can be recovered by distillation. Ha(12k)

DEFECTS (13)

Notes on Jackhammer Drill Steel. G. R. HEYWOOD. (Gen. Mgr., Rose Deep, Ltd.) *Mining Journal*, Vol. 169, June 28, 1930, pages 24–28.

Impact tests to destruction showed that (1) smoothness of bore was an important factor in the life of steel, (2) breakage was due to cracks starting from the bottom of minute corrosion pits in the bore of the steel (not to fatigue). Unforged shanks gave a marked increase in life. Failure of ¾-inch steel in the past has been due chiefly to breakage from heavy forging, not to inadequate cross section. Electric welding of broken steels prolonged their life but little. Various commercial brands are compared. AHE(13)

Failure of a Crankshaft. H. W. KEEBLE. *Metallurgia*, Vol. 2, May 1930, pages 35–36.

Gives results of a detailed examination of a crankshaft. The fracture was of the typical fatigue type. Microscopic examination indicates that the steel had been overheated and contained many inclusions. The shaft was poorly designed as there was an insufficient fillet at change of section. JLG(13)

Snow Flakes in Alloy Steel Forgings. H. H. ASHDOWN. *Iron Age*, Vol. 125, May 8, 1930, pages 1380–1381, 1429.

These defects usually lie beneath the surface of the forging and well removed from the ends. Presence of snow flakes is indicated by a type of hair line observed on longitudinal examination of finished machined forgings. All hair lines do not suggest the presence of snow flakes. Origin is in the ingot and mass action the ultimate cause. No form of heat treatment will correct it and the forgings are useless. Solid forgings may be re-worked to smaller sections. VSP(13)

Many Facts about Transverse Fissures yet to be Discovered. J. E. HOWARD. *Iron Age*, Vol. 125, May 22, 1930, page 1531.

Discusses the cause of an accident on Missouri Pacific Railroad. Summarizes the present status of transverse fissure problems. VSP(13)

Influence of Pores upon the Strength of Die Castings. (Der Einfluss von Poren auf die Festigkeit von Spritzguss.) L. FROMMER, W. KUNTZE & G. SACHS. *Zeitschrift Verein deutscher Ingenieure*, Vol. 73, Nov. 9, 1929, pages 2. 1609–1612; *Mitteilungen der deutschen Matrialprüfungsanstalten*, Vol. 13, 1930, pages 37–41.

Aluminum die castings were examined for porosity by means of X-rays and subjected to tensile tests. The tendency of breaking near the fillets was found to be the cause of greater variations in strength than the presence of pores. A number of specimens were cast in such a manner that they contained abnormally large pores. By suitable reduction of the specimen diameter fracture was obtained in the desired location. The pores were found to decrease the tensile strength in proportion to the decrease of actual cross section. No additional "notch" effect could be observed. These pores, which were much bigger than those commonly met with, caused variations within 10%, while the scatter limit of ordinary sound castings is 20%. X-ray examinations are recommended for the testing of die castings. Tensile specimens of the ordinary shape were found not to be suitable for establishing the influence of pores upon the strength of this material. Ha(13)

Crankshaft Fractures and Questions of Material. (Kurbelwellenbrüche und Werkstofffragen.) KURT MATTHAES. *Luftfahrtforschung*, Vol. 8, July 28, 1930, pages 91–120.

In operation of aeroplanes, fractures of crankshafts of six-cylinder engines have often occurred, the causes of which this paper attempts to explain. In a greater number of fractures which could be examined, the location of the fracture and its form was determined and conclusions drawn from it on the stresses which might have occurred. Chemical composition, structure and tensile properties, fatigue bending strength, torsional vibration strength, texture, defects of materials, and non-metallic inclusions were exactly examined. The frequency of fracture with age and the influence of refining on the life of a shaft are also considered. Suggestions are made for the prevention of such fractures. After all, it is stated that the question of crankshaft fractures is not a matter of material but rather of construction. Ha(13)

CHEMICAL ANALYSIS (14)

Application of Microscopic Analysis to Mixtures of Metals and Alloys. WILLET F. WHITMORE & FRANK SCHNEIDER. *Industrial & Engineering Chemistry, Analytical Edition*, Vol. 2, April 15, 1930, pages 173–176.

In order to employ microscopic qualitative analysis to the fullest extent in industrial work, a new system of separation of the metals has been developed. This eliminates the use of hydrogen sulphide, shortens the time of analysis, permits working with small amounts of material and dispenses with half the filtering operations required when the usual wet method of analysis is employed. 14 photomicrographs and 6 references are given. MEH(14)

Method for Determining Iron Oxide in Liquid Steel. *Foundry Trade Journal*, Vol. 42, April 24, 1930, page 313.

Brief discussion of method devised by the Metallurgical Section of Pittsburgh Experiment Station of the Bureau of Mines in coöperation with Carnegie Institute of Technology and the Metallurgical Advisory Board. It consists in killing a sample of liquid steel with excess of Al and determining the alumina formed. Killing is done with heavy Al wire in test spoon and not in mold. If killed in test mold, O may be lost at first moment of solidification or Al may segregate in the test piece. VSP(14)

The Quantitative Analysis of Steels by Spectrum Analysis. F. TWYMAN & A. A. FITCH; *Iron & Steel Industry & British Foundryman*, Vol. 4, Nov. 1930, pages 55–57; *Iron & Steel Institute, Advance Copy* No. 9, Sept. 1930, 12 pages.

7 references. A method for determining small amounts of common alloying elements in steels was developed. A logarithmic sector was used with a quartz spectrograph to form wedge spectra. The difference in length between a given iron wedge and a given wedge of the element to be analyzed was used in the analysis. The following elements can be determined with the accuracy indicated: Si up to 0.8%, accuracy 10% of content; Cr up to 4%, accuracy 5% of content; Ni up to 5% at least, accuracy 5% of content; Cu up to 1% at least, accuracy 5% of content. Methods for Mo and V can probably be developed. CHL+JLG(14)

Analytical Chemistry of Beryllium. (Beträge zur analytischen Chemie des Berylliums.) H. FISCHER. *Wissenschaftliche Veröffentlichungen des Siemens-Konzern*, Vol. 8, No. 1 (1929) pages 9–20.

Determination of Be in Cu, Ni or Zn alloys. 13 references. (14)

Terms of the Arc and Spark Spectra of Chromium. C. C. KIESS. *Bureau of Standards Journal of Research*, Vol. 5, Sept. 1930, pages 775–779.

Tables of terms are presented for the arc and first spark spectra of chromium. Babcock's unpublished Zeeman effects have aided in establishing many of them. Combinations of these terms account for nearly all the stronger lines of Cr I, and Cr II. All the terms which have been identified conform to the requirements of Hund's theory. (14)

The Determination of Chromium in Special Steels. (Die Bestimmung des Chroms in Sonderstählen.) P. KLINGER. *Archiv für Eisenhüttenwesen*, Vol. 4, July 1930, pages 7–15; *Stahl und Eisen*, Vol. 50, Aug. 14, 1930, pages 1166–1167, 3 references.

Report No. 75 of the Chemical Committee of the Verein deutscher Eisenhüttenleute. The known chemical methods on the determination of chromium in alloy steels were critically examined taking into consideration especially the influence of some alloying elements as for instance carbon, nickel, cobalt, vanadium, molybdenum and tungsten. Nine different methods were tested on 12 different steels. The permanganate-oxidation method in alkaline chloride solution with following oxidimetric or iodometric determination fails when Ni, Co, V, Mo and W are present. The elements have practically no influence on the other methods. The gravimetric chromium determination with mercurous nitrate cannot be applied for vanadium and tungsten steels without separating the elements. The permanganate-oxidation method cannot be used when larger amounts of nickel are present. This holds also for cobalt steels. The iodometric determination of chromium in vanadium steels can be used only in connection with the permanganate oxidation method in alkaline solution. The values obtained by other iodometric methods are too high. Copper, boron, aluminum, titanium, zirconium, tantalum and uranium have no influence on the determination of chromium. GN(14)

Determination of Oxides in Iron and Steel. (Beitrage zur Bestimmung der Oxyde in Eisen und Stahl.) F. MEISSNER. *Mitteilungen Forschungs-Institut Vereinigte Stahlwerke Aktiengesellschaft Dortmund*, Vol. 1, No. 9 (1930) pages 223–279, 90 references.

A general and critical review of all the methods for oxide determination in iron and steel such as chlorine, bromine, iodine, nitric acid, hydrogen reduction and microscopic examination. The Bromine and Iodine methods require a special treatment. By using the nitric acid method a great amount of residue is obtained, but also most of the oxides may be dissolved. An accurate determination of the oxides of manganese and iron is by the hot extraction with hydrogen, which reduces the oxides of iron at temperatures up to 1100° C. and the oxide of manganese at temperatures beyond 1000° C. When the carbon is high, the values obtained for the manganese and iron oxides are too low due to the reaction between the carbon and the oxides taking place at the temperatures of extraction. A new method developed only recently in Germany provides for this reaction between carbon and the oxides thus giving accurate values for the oxygen content in steel. GTM(14)

Streak Test for Platinum, Palladium and White Gold Alloys. (Strichprobe für Platin, Palladium und Weissgoldlegierungen.) HEINRICH MÜLLER. *Deutsche Goldschmiede-Zeitung*, Vol. 33, May 24, 1930, pages 4–5.

Describes rapid test for distinguishing between platinum, palladium and white gold. A streak of the material to be tested is treated with concentrated hydrochloric acid. If the streak is palladium it will turn a red brown, if a gold alloy the gold color will appear, and platinum as well as white gold made entirely of noble metals will not be attacked. If a drop of concentrated nitric is added to the drop of hydrochloric acid the cheaper white gold will dissolve, the platinum will be unattacked, and a white gold containing only noble metals will first turn green, then a gold color and will then be rapidly attacked. Chemical Analysis of Refractories. (Die Chemische Untersuchung von feuerfesten Stoffen. III.) H. J. VAN ROYEN & H. GREWE. *Archiv für Eisenhüttenwesen*, Vol. 4, July 1930, pages 17–21; *Stahl und Eisen*, Vol. 50, Aug. 28, 1930, pages 1229–1230.

Report 76 of the Chemical Committee of the Verein deutscher Eisenhüttenleute. The investigation was undertaken to find a quick and reliable chemical determination of chrome-bricks since most of the present methods do not fulfill these requirements. GN(14)

Determination and Separation of Zirconium and Beryllium. (Bestimmung und Trennung von Zirkon und Beryllium.) OTTO RUFF & EDWARD STEPHAN. *Zeitschrift für anorganische und allgemeine Chemie*, Vol. 185, Dec. 10, 1929, pages 217–220.

The determination of Zr as ZrP_2O_7 usually gives results which are too high but if, after the fusion with $KHSO_4$ in a Pt crucible, the Pt is removed by precipitation with H_2S in acid solution, a correction factor is unnecessary. Zr can be separated from Be by precipitating the former as phosphate in dilute H_2SO_4 solution. Then by adding NH_4OH the Be is precipitated as phosphate. The ignited $Be_2P_2O_7$, however, weighs a little too much; so it is necessary to use a factor for converting the weight of precipitate into the corresponding weight of BeO. (14)

Measurement of Hydrogen-ion Concentration and Applications to Metallurgy. (L'Indicé d'Adidité ou p.H. Mesure et Applications en Métallurgie.) M. BALLAY. *Aciers Speciaux, Métaux et Alliages*, Vol. 4, July 1929, pages 319–321.

The author reviews the methods of measuring pH values and discusses the value of such measurements in connection with electrolytic deposits and with corrosion phenomena. (14)

Notes on the Determination of Molybdenum. H. A. DOERNER. *Information, Circular* 6335, *United States Bureau of Mines*, September 1930, 3 pages.

A brief description is given of the determination of molybdenum. The difficulties most likely to be encountered and methods for their elimination are noted. AHE(14)

Determination of Aluminum and Magnesium in Zinc-Base Die-Casting Alloys. CHARLES M. CRAIGHEAD. *Industrial & Engineering Chemistry, Analytical Edition*, Vol. 2, April 15, 1930, pages 188–190.

Various methods applicable to the separation of aluminum and zinc in zinc-base die-casting alloys are discussed. The mercury cathode is suggested as a rapid and accurate method for the separation and determination of Al and Zn. A 2-gram sample of alloy is dissolved with 20 cc. of 1:1 sulphuric acid and 100 cc. of water. When all action has ceased, the solution containing the undissolved copper is transferred to the electrolytic beaker. The copper alloys with the mercury, 200 grams of which serves as the cathode in the beaker. The solution is electrolyzed for 5 hours, using a current strength of 1 ampere/6.25 cm.^{2}, and agitating the solution by compressed air. The solution is siphoned off, the beaker and electrode are washed 3 times before the circuit is broken, and the Hg (circuit broken) shaken with 25 cc. of water. To this solution 10 cc. of concentrated HCl are added and the Al is precipitated by the method of Blum (*Journal American Society*, Vol. 38 (1916) page 1282), by double precipitation. Mg is determined in the filtrate by a single precipitation as phosphate. 16 references cited. MEH(14)

Separation of Nickel and Cobalt by Means of Hypochlorite. F. H. RHODES & H. J. HOSKING. *Industrial & Engineering Chemistry, Analytical Edition*, Vol. 2, April 15, 1930, pages 164–166.

Nickel and cobalt can be separated from each other by fractional precipitation with sodium hypochlorite, the sharpness of the separation may be increased by effecting the precipitation in hot solution, by allowing the precipitated oxide to stand in contact with the solution for a considerable time, and by adding sufficient alkali to neutralize the free acid formed by the interaction between the cobaltous salt and the hypochlorite. Under proper conditions it is possible to precipitate most of the cobalt free from nickel and to leave a final residual solution containing most of the nickel free from cobalt, with but a comparatively small intermediate fraction which contains both metals. MEH(14)

The Titration of Potassium Cyanide, and of Free Cyanide in Silver-Plating Solutions, by Means of Silver Nitrate. EDWARD B. SANIGAR. *Preprint* 58–5, *American Electrochemical Society*, Sept. 25–27, 1930, pages 49–68.

The effect of the presence of carbonate on the titration, by silver nitrate, of potassium cyanide solutions, and of the free cyanide present in silver-plating solutions, has been studied. The presence of carbonate has been shown to give rise to persistent precipitates during titration of the cyanide. The formation of these precipitates has been shown to be avoidable by the use of dilute solutions. Apart from these precipitates, carbonates were found not to interfere with these titrations. The removal of the carbonate by barium nitrate, barium chloride, calcium chloride or strontium nitrate was found to produce erroneous results, and to complicate the titrations by promoting precipitate formation. Additions of small amounts of N/10 sodium hydroxide were found to be without effect on the titration result, or on the formation of precipitates. Titration of the cyanide without using potassium iodide as indicator was found to yield slightly higher results. It was found that additions of ammonium hydroxide obviated precipitate formation, but that the concentration of ammonia had to be correlated carefully to the amount of potassium iodide used as indicator, if accurate results were to be obtained. (14)

The Determination of Silica in Ferrosilicon in the Presence of Silicon. (Die Bestimmung von Kieselsäure neben Silizium in Ferrosilizium.) A. STADELER. *Archiv für Eisenhüttenwesen*, Vol. 4, July 1930, pages 1–6; *Stahl und Eisen*, Vol. 50, Aug. 7, 1930, pages 1132–1133, 11 references.

Report No. 74 of the Chemical Committee of the Verein deutscher Eisenhüttenleute. The determinations were made by means of the chlorine method which is described in detail and which was developed due to the experience during the investigation. Ferrosilicons with 11%, 45% and 90% ferrosilicon were examined. Special tests were carried on on the possible loss of material during the process of chlorination, the best suitable temperature and the velocity of the chlorine gas. Uniform silica contents are found for temperatures between 500 and 600° C. whereas the values essentially decrease for temperatures between 625 and 650° C. The most suitable temperature is 500° C. A gas velocity of 10 liters per hour seems to be most suitable. The silica values fluctuate nevertheless and are 0.06–0.10% for the 11% ferrosilicon, 0.14–0.26% for the 45% ferrosilicon and 1.00–1.32% for the 90% ferrosilicon. Silica is probably present in ferrosilicon as impurity. The method of crushing ferrosilicon samples is of importance. Heating up in crushing must be avoided since the silica content depends upon the heating up of the sample. In crushing with an air hammer the silica content of 90% ferrosilicon samples increased from 0.37–0.62% after 10 minutes and to 1.09% after 30 minutes crushing. In crushing in an agate mortar practically no influence of the time of crushing was found. GN(14)

Volumetric Determination of Carbon in Difficultly Combustible Iron and Steel Alloys. (Zur volumetrischen Kohlenstoff-Bestimmung in schwer brennbaren Eisen- und Stahllegierungen.) E. ZINDEL. *Chemiker-Zeitung*, Vol. 53, Nov. 16, 1929, page 891.

As catalyst to be used instead of Bi_2O_3 it is often useful to mix some mild steel of known C content with samples which are otherwise difficult to burn. (14)

Quantitative Spectroscopic Analysis of Metals and Alloys. *Metallurgist*, Oct. 1929, pages 149–150.

Notes on the use of spectroscope in qualitative analysis; on attempts at quantitative work; and on the relative advantages in the use of arc and of spark sources. (14)

Determination of Chromium and Vanadium after Oxidation with Potassium Bromate. I. M. KOLTHOFF & ERNEST B. SANDELL. *Industrial & Engineering Chemistry, Analytical Edition*, Vol. 2, April 15, 1930, pages 140–145.

The determination of chromium by addition of excess arsenious oxide to an acid chromate solution and back-titration with permanganate has been investigated systematically. Good results are obtained in the presence of vanadium, ferric iron and manganese at various acid concentrations. After chromium has been determined vanadate can be titrated in the same solution with ferrous sulphate, diphenylbenzidine being used as indicator. Oxidation of chromium and vanadium to chromate and vanadate, respectively, is effected by use of potassium bromate; the excess bromate is removed by boiling with ammonium sulphate. The method can be applied to the rapid determination of Cr and V in alloy steels. Tungsten interferes in the titration of V and must be removed. The time required for the total determination of Cr and V, including dissolving of the steel, is one hour or less, 11 references. MEH(14)

Titrometric Determination of Magnesium. J. STANTON PIERCE & M. B. GEIGER. *Industrial & Engineering Chemistry, Analytical Edition*, Vol. 2, April 15, 1930, pages 193–194.

In this work Mg is precipitated as the hydroxide with standard carbonate free alkali. When the endpoint for trinitrobenzene (a dark brick red) is obtained, the Ca remains in solution. The solution containing the precipitate is diluted to a definite volume, an aliquot part filtered and the excess alkali titrated. The accuracy of the method depends upon the completeness of precipitation of Mg, with Ca remaining in solution, and the endpoint when the excess alkali is titrated. The method which has been used with limestone analysis is given in detail. 9 references. MEH(14)

Confirmatory Test for Zinc. J. STANTON PIERCE & ETHYL D. NAVE. *Industrial & Engineering Chemistry, Analytical Edition*, Vol. 2, April 15, 1930, page 190.

The ferrocyande titration of zinc, with uranyl acetate as inside indicator can be used as a confirmatory test for zinc in qualitative analysis if interfering ions are first removed. MEH(14)

Molybdenum in Special Steels. (Le Molybdene dans les aciers speciaux.) *Aciers Speciaux, Métaux et Alliages*, Vol. 5, Jan. 1930, pages 27–32.

In a chronological order information is given about the researches carried out at the Creusot Works, France, where in 1894, Molybdenum Steel was for the first time produced, followed with Cr-Mo steel in 1895, Ni-Mo steel in 1895 and Ni-Cr-Mo steel in 1905. Most of these alloy steels were used in manufacture of munitions. GTM(15)

ECONOMIC (16)

Gold, Silver, Copper, Lead and Zinc in Washington in 1928. C. N. GERRY. *Mineral Resources of the United States*, 1928, part 1, Aug. 6, 1930, pages 689–703, *United States Bureau of Mines.*

The value of the mine production of gold, silver, copper, lead and zinc in Washington in 1928 ($633,156) was 26% less than in 1927 and much less than the average for the decade. Gold output decreased more than 16%, silver 36% in quantity, copper 30% in quantity and zinc more than 93%. Lead production increased 14%. AHE(16)

Gold, Silver, Copper, Lead, and Zinc in Idaho in 1928. C. N. GERRY. *Mineral Resources of the United States*, 1928, part 1, Aug. 6, 1930, pages 645–687, *United States Bureau of Mines.*

The value of mine production of gold, silver, copper, lead and zinc in Idaho decreased from $28,104,413 in 1927 to $26,667,706 in 1928, largely due to the large decline in lead production. The quantity of copper decreased 5%, but the value increased by the same amount. Gold output increased 37% over 1927. Silver production increased slightly. Lead decreased 4% in quantity and 11% in value! Zinc production increased 17%. AHE(16)

Mineral Resources of the United States, 1929. Preliminary Summary. FRANK J. KATZ & MARTHA B. CLARK. *United States Bureau of Mines*, July 1930, 120 pages.

The value of all mineral products in 1929 was $5,830,000,000, 8% more than 1928. The total value of the metallic products increased 15% and has been exceeded only in 1920 and 1923. Except for gold and silver all important metals contributed to this, copper accounting for nearly one-half. Smelter output of copper increased 10% in quantity and 34% in value. Production of copper outdistanced consumption. Steel production reached a new high level, exceeding 1928 by 9%. Shipments of pig iron also increased 8%. Production of high-grade manganese ore in 1929 showed the first increase since 1925. Mercury production was 1/3 greater than in 1928 and was the largest output since 1918. Gold production declined about 1%. AHE(16)

Cost of Using Welding. ROBT. E. KINKEAD (Consulting Engineer). *Journal American Welding Society*, Vol. 9, Sept. 1930, pages 19–22.

Points out difficulty of determining actual welding costs from figures obtained by using the cost indicator, labor, material and overhead. Stresses need of an additional cost indicator based upon the economic value of the product as obtained from life tests. LFM(16)

Gold Production and Its Future. H. A. KURSELL. *Booklet, American Smelting & Refining Co.*, April 9, 1930, 12 pages.

Gold production in various countries detailed. (16)

Engineering Markets of the World—IV. A. J. LIVERSEDGE. *Engineering*, Vol. 130, Sept. 5, 1930, pages 301–304.

Deals with trade situation in Australia giving tables of figures for following classes of engineering materials: metals and all manufactures of metals, iron and steel and manufactures thereof, machinery, vehicles and electrical apparatus. Regrets fact that United Kingdom is supplying only 1/3 of Australian imports of these materials while United States is supplying 1/2. Australia favors British Empire in matter of tariff. Merchant iron and steel, certain classes of wire, automobile parts, typewriters, etc., are admitted free from the United Kingdom. The curve showing imports of iron and steel from other sources than the United Kingdom shows decline since 1913. This is the only class showing such a decline. New Zealand buys more of these commodities per head than does Australia. Her tariff preference to the Empire is generous. Bolts and nuts, most classes of iron and steel, and some types of machinery are free to British manufacturers. There was a decline in engineering imports from the United Kingdom from 52.3% in 1928 to 47.6% in 1929. In the case of general iron and steel the British Empire seems to be doing as well as can be expected. Tables and graphs are given. LFM(16)

Production Cost for Welded and Cast Parts. (Gestehungskosten für geschweisste und gegossene Teile.) F. SIEBEL. *Elektrotechnische Zeitschrift*, Vol. 50, Feb. 27, 1930, page 339.

Two formulas for the production cost of welded and cast parts are developed which permit one to state clearly whether in a given case it would pay to make a pattern and cast the pieces or if it would be cheaper to weld the parts together from standard structural shapes. Ha(16)

Chinese Tungsten. *Chemical Engineering & Mining Review*, Vol. 22, July 5, 1930, pages 356–357.

Tungsten deposits are found in several northern provinces of China. China is credited with over 50% of the tungsten production of the world. WHB(16)

German Machine Tools in the World Markets. *Engineer*, Vol. 150, Aug. 15, 1930, page 177.

From article appearing in *Rhein-Westfulische Zeitung*. Official export statistics of Germany show that weight of exports of machine tools increased by 30% in the first half of 1930 and in value by 16% over corresponding period of 1929. Lists countries in order of their importance as purchasers of various types of machine tools. LFM(16)

Iron and Steel Industry for British Columbia. *Engineer*, Vol. 150, Aug. 22, 1930, pages 210–211.

Comments on reports concerning progress made in establishing a steel industry on the coast of British Columbia. The Freyn Engineering Company of Chicago is financing the scheme up to 23 million dollars. A 30 years' supply of iron ore is available as well as deposits of limestone and suitable coal for smelting purposes. Average iron ore content was found to be 61.7% from 16 drill holes. Ore is low in P, silica and alumina, has satisfactory Mn content and contains no Zn, As or Ti. LFM(16)

The Export Trade of France in Electric Furnace and Electrolytic Products. (La Commerce exterieure de la France en produits du four electrique et electrolyse en 1929.) *Journal du Four Electrique*, Vol. 39, Apr. 1930, pages 130–131.

A survey of French export trade in products made in electric furnaces and by electrolyis. JDG(16)

Norwegian Business in Electric Furnace Products. (Le commerce norvegien de produits du four electrique.) *Journal du Four Electrique*, Vol. 39, Mar. 1930, page 97.

A brief survey of Norwegian business in products made in electric furnaces. JDG(16)

Concrete Bar Trend is Westward; Large Jobs More Numerous. W. H. LLOYD. *Iron Trade Review*, Vol. 86, March 20, 1930, pages 45–47.

Survey of distribution in United States for last half of 1929. MS(16)

America's Surplus Scrap Supplies Europe and Orient. J. JOSEPH W. PALMER. *Iron Trade Review*, Vol. 86, Feb. 13, 1930, pages 49–50.

Over 500,000 gross tons of scrap was exported to 31 foreign markets in 1929. This tonnage was located too far from domestic melting centers to allow it to complete with other steelmaking materials, because of the freight charges. Cheap water transportation permits exportation to countries lacking material, such as Japan, Italy and Poland. MS(16)

Large Individual Awards Keep East in Structural Limelight. W. H. LLOYD. *Iron Trade Review*, Vol. 86, March 6, 1930, pages 81–84.

Survey of the distribution of structural steel in the United States for last half of 1929. MS(16)

PLANTS & LABORATORIES (17)

Fabricates Electrically Welded Steel Tubing in New Plant. A. H. ALLEN. *Iron Trade Review*, Vol. 85, Oct. 31, 1929, pages 1091–1093.

Steel & Tubes, Inc., has recently put into operation a new plant at Ferndale, Mich. Cold-rolled strip, 0.016–0.140 in. thick, is received in coils 150-400 ft. long. Material is a mild steel containing 0.08–0.12% C. These coils are rewound into coils 3000–3500 ft. long by special reeling machines. The strip is then fed to the electric welding machines which electrically butt weld the seam, cut the tubing off in standard mill lengths ranging from 12 ft. up, and eject it at the rate of about 60 ft. per min. There are six of these units, each of which has a capacity of 2000–2500 ft. per hr. They are equipped to make tubing 3/16–4 in. in diameter. After the tubing is formed and welded it is put through any required finishing processes. MS(17)

Modern Plant for Malleable Castings. *Iron Age*, Vol. 125, May 1, 1930, pages 1285–1289.

Describes plant of the United States Expansion Bolt Co. Annealing is done in tunnel kiln. Producer gas from hard coal is used. Air furnace fired alternately with oil and coal. Numerous illustrations. VSP(17)

Forging Practice Modernized by Mechanical Handling. C. B. PHILLIPS. (Surface Combustion Co.) *Iron Trade Review*, Vol. 86, March 6, 1930, pages 85–86, 92.

Describes equipment and practice of a plant for making rotary tool joints from alloy steel. Forging furnace is a continuous pusher-type, gas-fired billet heating furnace. It has preheating, heating and soaking zones, the parts being heated to 2300° F. The normalizing furnace is of the same general construction as the forging furnace. The highest temperature used in this furnace is 1650° F. MS (17)

Routing and Production System Affords Quick Shipment. H. R. SIMONDS. *Iron Trade Review*, Vol. 86, Feb. 27, 1930, pages 55–58, 76.

Describes operations of the Allied Die Casting Corp., Long Island City, N. Y. MS(17)

Rolling of Large Aluminum Structural Shapes. *Rolling Mill Journal*, Vol. 4, March 1930, pages 89–93.

Description of the rolling mill of the United States Aluminum Co. at Massena, N. Y. MS(17)

Razor Parts Gold Plated at Rate of 100,000 a Day. H. R. SIMONDS. *Iron Trade Review*, Vol. 86, Feb. 13, 1930, pages 51–53.

Describes operations of the American Safety Razor Co., Brooklyn, N. Y. Base metal used is brass. Pieces undergo thorough grinding, polishing, cleaning, rinsing and drying prior to plating. Pure gold anodes are used. Gold cyanide bath is freshened daily. Current is 60 amperes at about 3 1/2 volts. MS(17)

Stamping Plant Enjoys Steady Growth. A. H. ALLEN. *Iron Trade Review*, Vol. 86, March 27, 1930, pages 53–56, 71.

Deals with the Geometric Stamping Co., Cleveland. VSP(17)

Open-Hearth Furnace Steelworks. A Comparison of British and Continental Installations and Practice. H. C. WOOD. *Iron & Steel Institute, Advance Copy* No. 11, Sept. 1930, 32 pages.

Modern open-hearth design and layout is discussed, and various European plants are described in some detail. The author concludes that Continental steelworks furnaces are generally in advance of those in Great Britain. Best available mechanical equipment is universally employed. JLG(17)

Empire Platinum Refining in Great Britain. Acton Works to Be the Biggest in the World. *Mining Journal*, Vol. 169, June 28, 1930, pages 6–7.

The Acton refinery now has a minimum capacity of 300,000 ounces of platinum metals per year. The proportion of production of the various metals is roughly platinum 47%, palladium 39%, rhodium 4%, ruthenium 2%, iridium 1% and gold 7%. The average purity is platinum 99.93%, palladium 99.94%, rhodium 99.76%, ruthenium 99.72%, iridium 99.68%, gold 99.97% and silver 99.97%. The flow sheet is given. The chief feed at present comes from the Mond Nickel Refinery at Clydach and contains large amounts of silver and lead. Cupellation removes excess lead as litharge. Silver is dissolved in sulphuric acid. Aqua regia treatment of the residue gives a solution of platinum, palladium and gold. The platinum is precipitated as platinichloride, and the palladium as palladosamminechloride, which on ignition give sponge metals. Gold and silver are purified by electrolysis. The aqua regia insolubles contain the other rare metals. AHE(17)

Divers Heat-Treating Machines. FRED M. REITER. (Dayton Power & Light Co.). *Iron Age*, Vol. 125, May 15, 1930, pages 1449–1451.

Describes equipment installed by Dayton Forging & Heat Treating Co. Complete automatic control installed and full record maintained. Usable furnaces were reconditioned while obsolete equipment replaced. Natural gas replaces oil fuel, formerly used. Gives list of new equipment installed. VSP(17)

Replaces Fifty Year Old Furnace. *Iron Age*, Vol. 125, June 12, 1930, pages 1750–1751, 1795.

Wisconsin Steel Co. of South Chicago replaces an old hand filled blast furnace of 250 ton capacity with a new stack of 600 ton rating. Gives a description of the new furnace. VSP(17)

A New Engineering Laboratory. F. V. LARKIN & S. S. SEYFERT. *Mechanical Engineering*, Vol. 52, Oct. 1930, pages 883–887.

A description of the James Ward Packard Laboratory of electrical and mechanical engineering at Lehigh University, and of the principles involved in its design and construction and operation, GN(17)

Aluminum Research Program Extended. *Automotive Industries*, Vol. 63, July 5, 1930, pages 13–14.

The new laboratories of the Aluminum Company of America at New Kensington, Pa. are briefly described. GN(17)

Scientific Control in the Production of Bronze Castings. *Brass World*, Vol. 26, Sept. 1930, pages 233–236.

A glimpse of the new foundry of the National Bronze Co. Ltd. in Montreal. This foundry started operation early in 1930 and is now turning out 30,000 lbs. of castings per day. Both electric arc and gas-fired crucible furnaces are employed. A completely equipped control laboratory has been provided. WHB(17)

Modern Foundry Layout. *Metallurgia*, Vol. 2, July 1930, pages 77–80 and 83.

Describes the foundry at Morris Motors Ltd., which was designed to produce castings for 1000 motors weekly. The building has 7 bays, each 25 feet wide. It contains 3 Pneulec cupolas, each 3 1/2 feet in diameter at the melting zone. JLG(17)

Drawn Stampings of Rustless Steel. *Iron Age*, Vol. 125, June 12, 1930, pages 1755–1757.

Describes the production of rustless hub, radiator and gas tank caps by the Eaton Axle and Spring Co., Cleveland. It has a capacity of 1,000,000 caps and the same number of necks and flanges. Steels used are a high Cr-Ni containing 18% Cr and 8% Ni, and the other an 18% Cr and no Ni. Plain Cr steel is suitable for caps requiring only slight draw. Cold rolled steel, mostly 0.025 in. gage, is used for caps. The deepest drawing required of any part is 1 1/8 inch on the lower section of radiator caps. Radiator necks are made of strip brass. Plain C steel caps are plated. The usual sequence of operation is Cu plating, Ni plating, Ni buffing, Cr plating and Cr buffing. VSP(17)

FOUNDRY PRACTICE & APPLIANCES (22)

Essential Properties of Molding Sands. A. H. Dierker. *The Steel Founder*, Vol. 1, May 1930, page 16.
Short discussion. MLM(22)

Preliminary Studies of the Effect of Deoxidation and Mold Conditions on the Tensile Properties of Carbon Steel Castings. J. V. McCrae & R. L. Dowdell. *Bureau of Standards Journal of Research*, Vol. 5, Aug. 1930, pages 265–277.
Foundrymen occasionally experience difficulties with steel castings in meeting ductility specifications of 24% elongation and 35% reduction of area if the steel is deoxidized with aluminum shortly before pouring the castings. Sound castings can usually be obtained in dry sand molds without the addition of "deoxidizers" immediately before pouring. Green sand molding is generally desired but porosity, as "pinholes," often occurs. Aluminum and other "deoxidizers" studied eliminated porosity but lowered the ductility. The mold conditions are probably the important variables responsible for pinholes. A sufficient amount of "deoxidizer," however, should be in the steel at the time of pouring to deoxidize the steel from the gases evolved from the moisture contained in the mold. (22)

Steel Foundry Complexities. Frederick A. Melmoth. *Canadian Chemistry & Metallurgy*, Vol. 14, Aug. 1930, pages 240–242, 244, 246.
Steel foundry complexities may be grouped as: (1) metallurgical, (2) mechanical, (3) administrative. Melmoth considers chiefly the first group. (22)

The Detroit Rocking Electric Furnace as Applied to the Production of High Test Gray Iron. Carl H. Morken. *Preprint* 58–17, *American Electrochemical Society*, Sept. 25–27, 1930, pages 229–240.
Utilization of the electric furnace has enabled the small as well as the large foundry to produce high test gray iron. The Detroit rocking electric furnace is described, and it is shown how this furnace is used for smelting and processing gray iron. Operating data and costs are given with the properties of the iron. The rocking action of this furnace has a marked effect upon the properties of the iron. With this furnace, high test gray iron can be produced at costs below those of cupola iron. (22)

Progressive Foundries Secure Work in Lean Times. *Metallurgia*, Vol. 2, July 1930, pages 94–96.
Foundries that have shown real advancement in development and in installation of modern equipment are kept busy, while others are idle. Describes several well ordered foundries. JLG(22)

Some Notes on Foundry Equipment and Appliances. *Metallurgia*, Vol. 2, July 1930, pages 109–112.
Describes sand testing equipment, mixing machines, ovens, melting furnaces and cleaning equipment. JLG(22)

Production of High Test Cast Iron. G. Neuendorff. *Metals & Alloys*, Vol. 1, July 1930, pages 620–625.
A correlated abstract. Keep observed in 1898 that low silicon cast iron is less sensible to the cooling rate than high silicon iron due to decreasing graphite crystallization with decreasing silicon content. In 1906 Goerens indicated that cast iron to yield its best properties should be in a pearlitic condition. The Diefenthäler patent yields Lanz pearlitic iron. It is obtained by carefully selecting composition varying with the cross section of the casting and heating the sand molds, to obtain a suitable cooling rate. Bauer reported data on structure and physical properties. The pronounced resistance to abrasion and high stability of volume of pearlitic cast iron are highly useful properties. Coincidently considerable attention was diverted to the desirable properties resulting from finely divided graphite crystals. Sipp, Bauer and Maurer commented on this. Bardenheuer and Zeyen indicate that if coarse graphite crystallization is avoided, improvements in physical properties can be obtained by influencing the ground mass. Wüst and Leyde pointed out the desirability of kind and size of graphite rather than the quantity of it. Wüst and Kettenbach found that bending strength tensile strength and hardness generally decrease with increasing carbon content. Emmel developed the cupola process suitable for manufacture of 3% carbon high test cast iron. Krupp "Sternguss" and the Ross Mechan "Mechanite" are similar products. The Corsalli process for manufacture of low carbon cast iron is also satisfactory. Shüz obtained the graphite eutectic with 3% silicon and subsequent heat treatment. Piwowarsky and Northcott indicate an increase in graphite with higher casting temperature whereas Hailstone, Murakami and Honda observed the converse. Hanemann pointed out the need for consideration of the velocity of solution of the graphite nuclei in the melt. He explains Piwowarsky's reversal. This resulted in a practical procedure; viz., super-heating at a lower temperature for a longer period. Bardenheuer and Zeyen observed that the physical properties depended largely on the carbon content. These data are included. Low carbon melts show a decrease in physical properties, whereas melts with high carbon content show an essential improvement which is due to a fine graphite crystallization. The Wüst furnace for superheating is a combination of cupola and oil-fired furnace. The Deschesne method using a cupola forehearth which is lifted by means of 2 trunnions about 100 times a minute. Various observations throw doubt on this method. The electric furnace is highly satisfactory. Kerpely produced high test cast iron even with high phosphorous content. The Brackelsberg furnace permits rapid melting, and consequent reduction of oxidation; the slag layer of the metal bath prevents saturation with gases and oxides. This results in a cast iron with a dense structure free from cavities, holes and pipes. The molten metal has a high fluidity. The furnace is of abnormally high thermal efficiency. Hatfield, Piwowarsky and Smalley observe slight beneficial effects from alloying cast iron. Data regarding the effect of a variety of constituents are included. Correction see *Metals & Alloys*, Vol. 1, Sept. 1930, page 702. ESC(22)

Some Technical Aspects of the Electric Steel Foundry. D. K. Barclay. *Foundry Trade Journal*, Vol. 42, April 10, 1930, pages 269–271, 276.
Paper read before Middlesborough section of the Institute of British Foundrymen. Concerned with a 7-ton Herault type furnace worked with a basic hearth. Describes steel making process. Reactions taking place are as follows: The carbon combines with iron oxide forming carbon monoxide and iron; manganese and silicon are oxidized to manganous oxide and silica. Elimination of phosphorus proceeds, in combination with iron oxide the pentoxide is formed, which in turn combines with lime to form calcium phosphate. A typical dephosphorizing slag by partial oxidization method is as follows: SiO_2 16.26; FeO 8.41; Al_2O_3 2.84; MnO, 4.37; CaO, 53.23; MgO 13.78; and P_2O_5, 9.82%. Hot pouring allows solid non-metallic inclusions and gases to rise to the top, but it favors segregation, cracking, excessive shrinkage, burning-on and very often is responsible for ingotism. Cold pouring means quick solidification with less risk of cracking but does not always give sharp impressions of the mold, also short runs and overlaps. Describes molding sands to be used. Other topics taken up are drying of cores and heat treatment of castings. VSP(22)

Monel Metal Castings. Fred M. Chambers. *Metals & Alloys*, Vol. 1, July 1930, page 619.
Technique for manufacture of a variety of good Monel castings is described. ESC(22)

Power for Moulding Machines. A. S. Beech. *Metallurgia*, Vol. 2, Sept. 1930, pages 172, 188.
The author discusses the merits and demerits of the various motive powers employed in the foundry. GTM(22)

MOORE RAPID 'LECTROMELT FURNACES

Lectromelt

Recent 500 lb. per hour 'LECTROMELT furnace installation for special alloy work.

'LECTROMELT furnaces offer the rapid and economic means of producing stronger, denser, cleaner and closer grained irons and steels under constant analytical and temperature control.

Over 40 users making corrosion and heat resistant irons and steels.

FURNACES & FUELS (23)

Fuel Oil for Industrial Furnaces. L. D. Becker. *Advance Paper, American Society of Mechanical Engineers*, Oct. 7–10, 1929, 5 pages.

Describes improved designs in furnaces that have resulted in oil-fuel economy. Types of furnaces in which oil is used as fuel are cited and the advantages of oil as a fuel explained. (23)

New Methods for Chemical Utilization of Coal. (Les nouvelles methodes d'utilization chimique du charbon.) Ch. Berthelot. *Revue de Metallurgie*, Vol. 27, 1930, pages 381–391.

A sketch of the present tendencies for utilization of coal including catalytic preparation of organic compounds and liquefication of coal. JDG(23)

The New Open Hearth Furnace "Terni." (Les Nouveaux fours Martin à grande production de la Societe "Terni.") G. B. Bruno. *Aciers Speciaux, Métaux & Alliages*, Vol. 5, March 1930, pages 99–106.

The new open-hearth furnace "Terni" is a revolution in metallurgical industry through its performances and characteristics. A new trend to produce a more intense combustion is shown in the Moll and Lackner open-hearth furnaces, but "Terni" furnace surpasses them. The first "Terni" furnace was put into operation in 1926, producing any kind of steel. From experiments carried on during two weeks, this furnace produced about 8.2 tons per hour, in average charges of 50 tons. The principal characteristics of this furnace are: (1) A special combustion chamber, preheated gas and air are intimately mixed and this mixture is further diluted in the furnace with new supply of air. (2) Means to vary the velocity of the flame. (3) Means to control the quantity and type of the flame and combustion, different than the ones already in use in the open-hearth. (4) High temperature of recuperation for air and gas, at 1350° C. (5) Long run of furnace with less necessary repairs. (6) No complications of the water cooling system. (7) Facility to make any type of high quality steel in this furnace. GTM(23)

High-Frequency Steel Furnaces. D. F. Campbell. *Iron & Steel Institute, Advance Copy* No. 1, Sept. 1930, 10 pages; *Iron & Coal Trades Review*, Vol. 121, Sept. 26, 1930, pages 458–459; *Engineering*, Vol. 130, Sept. 26, 1930, pages 409–411.

Ironless induction furnaces melting 25 cwt. of steel have been used, and furnaces that would melt up to 5 tons could be designed. The high frequency furnace has been used in melting tool steels, low carbon alloys, various heat-resistant alloys, and in melting rolling mill scrap. It has not been often used as a refining furnace, but the refining action is rapid and it might be used in place of the open-hearth. In comparison to the open-hearth the heat is more efficiently used, and the investment is much less. The high frequency furnace is suitable for making all grades of high and medium quality steel, except where very large castings are required. Time and power records are given for several furnaces melting various steels. LFM+JLG(23)

Some Further Notes on Gas and Air Blast Apparatus. H. R. Hems. *Gas World*, Vol. 91 (Supplement), Sept. 21, 1929, pages 11–15.

Treats the following subjects: (1) direct fired furnaces, (2) surface combustion type oven furnace, (3) recuperative furnaces, (4) recent design of oven furnace, (5) regenerative types, (6) method of operation, (7) high speed steel furnaces, (8) forging furnaces. (23)

Electric Furnace Transformers. (Les Transformateurs pour Fours Electriques.) G. Marty. *Aciers Speciaux, Métaux et Alliages*, Aug. 1930, Vol. 5, pages 360–370.

After giving a short description of the particular advantages of electric furnaces indicating special qualities of the transformers, the author describes the characteristics of the transformer especially built to carry 100,000 amperes. GTM(23)

The Use of Gas in the Preparation of Non-Ferrous Metals. (Ueber die Verwendung des Gases zur Verarbeitung der Nichteisenmetalle.) M. Meier. *Metallwirtschaft*, Vol. 9, June 20, 1930, pages 521–525.

Describes the processes and gas furnaces and apparatus used in the preparation and working of non-ferrous metals, such as Cu melting, Cu drawing, tinning of Cu wire, melting of type metals, bearing metals and die castings, melting Ag and Au, Ag and Au soldering, heat treating Al alloys. Details of construction, including illustrations, advantages over other methods of heating, ease of control and comparative costs are discussed. CEM(23)

Heating Up of Small Industrial Furnaces with Coke Oven Gas. (Das Anheizen kleiner Industrieöfen mit Koksofengas.) H. Repky. *Stahl und Eisen*, Vol. 50, Sept. 4, 1930, pages 1270–1272.

Two essentially different types of furnace were examined: furnaces with direct heating, that means the burners are directly inserted in the furnace; and furnaces with indirect heating, which means the burners are inserted in a combustion chamber underneath the hearth of the furnace. Time-temperature heating diagrams are presented and discussed for furnaces of various capacities. GN(23)

The Coreless Induction Furnace. A. G. Robiette. *Metallurgia*, Vol. 2, July 1930, pages 105–108.

The original Ajax-Northrup furnace supplied with high frequency current by a spark gap was satisfactory for small furnaces, but is not suitable for large furnaces. The large furnaces can be operated economically at frequencies that can be obtained from a generator. A 5 cwt. furnace operates well with a 2200 cycle current and a one ton furnace can be operated with 1000 or less cycle current. The furnaces make a highly inductive load, with a very low power factor, which can be compensated with condensers. In the larger units it is possible to switch in or out part of the condensers and keep the power factor at unity. Linings are now frittered in by heating a metallic template embedded in the loose refractory that is to be the lining. The template may be the first charge. An average life of about 60 heats has been obtained with these linings. The motion produced in the metal by the current is an aid to refining. Contains 2 references. JLG(23)

The Penetration of Heat into the Charge During the Annealing of Brass Plates. (Das Eindringen der Wärme in die Glühhaufen beim Ausglühen von Messingblechen.) W. Roth. *Zeitschrift für Metallkunde*, Vol. 21, Dec. 1929, pages 414–415; *Metal Industry* (London), Vol. 36, April 11, 1930, pages 403–404.

A study was made to investigate the penetration and distribution of heat in brass plates of 3,000, 1 000 and 120 kg. in annealing furnaces under varying conditions. The temperature during annealing of several hours was closely followed by means of numerous thermocouples and the most economic use of the furnace derived from the heating curves, showing that a more uniform heating is obtained with smaller charges or with divided charges. Pressing plates tightly together results in a more rapid and uniform heating. Electrical heating is recommended. VSP+EF(23)

Three-Phase Arc Furnaces. (Der Drehstrom-Lichtbogenofen.) Siegmund Schey. *Giesserei Zeitung*, Vol. 26, Oct. 15, 1929, pages 583–587.

Different parts of the equipment of electric steel furnace are described. On the basis of this, aspects for correct design are discussed. Details are given of reactance choking coils, electrode regulation and high-voltage switch-gear. (23)

Making One's Own Electric Resistance Furnaces. (Die Eigenherstellung von elektrischen Widerstandsöfen.) Erich Schwarz-Bergkampf. *Chemische Fabrik*, Vol. 2, Dec. 11, 1929, pages 519–520.

Directions are given for constructing Cr-Ni wire furnaces for temperatures up to 1000° C., and for changing the connections of the Siemens-Müller 110 volt furnace for other voltages. (23)

Scientific Foundations of the Thermal Features of Industrial Furnaces. (Les bases scientifiques thermiques des fours industriels) G. Zotos. *Revue de Metallurgie*, Vol. 27, July 1930, pages 352–361.

Theoretical discussion of the factors involved in furnace design. JDG(23)

Melting Furnace Fired by Coke or Oil. *Brass World*, Vol. 26, July 1930, page 185.

The Monarch Engineering & Manufacturing Co., Baltimore, Md. has placed on the market a metal melting furnace that can be changed over to use either gas or oil or coke, coal or wood for fuel. It can be changed over for use with an oil or gas burner when such equipment becomes available or desirable. Coke can be used in combination with oil to produce high efficiency and save time. If oil or gas are to be employed regularly the grate bars at the bottom may be bricked over and a pot of 275 lbs. capacity installed to replace the 150-lb. pot used with the combination arrangement. The furnace is claimed to be good for melting red or yellow brass, copper, bronze, aluminum, iron, etc. WHB(23)

Electric Nitriding Furnace. *Canadian Chemistry & Metallurgy*, Vol. 14, Aug. 1930, page 246.

The Canadian General Electric Co. Ltd. has developed a line of nitriding furnaces of the box type with swinging door, an inner retort, and a charging truck for handling the retort. Temperature control is automatic and cast iron rollers are provided in the floor of the furnace for convenience in handling the charge retort. A charging truck has rollers. The furnace is available in several sizes. WHB(23)

Cracking Device Makes Substitute for Hydrogen. *Electrical World*, Vol. 96, July 26, 1930, page 194.

"Electrolene" is produced by feeding steam and gas, or other hydrocarbons, into an electric cracking device developed by the General Electric Co. The heat necessary for the cracking is generated by electricity. "Electrolene" can be produced at about one-tenth the cost of hydrogen and consists principally of hydrogen and carbon monoxide. It is valuable for use in electric furnaces with controllable atmospheres, in heat treatment work, brazing, etc. WHB(23)

Armas System of Automatic Electrode Control. (La regulation automatique des electrodes systeme Armas.) *Journal du Four Electrique*, Vol. 39, May 1930, pages 179–189.

A description of hydro-electric electrode regulator in which the inertia of the moving part is reduced to a minimum. JDG(23)

Pulverized-Fuel Firing for Metallurgical Work. *Metallurgia*, Vol. 2, June 1930, pages 41–44.

The advantages of using pulverized coal in metallurgical processes are stressed. Pulverized fuel can be used economically in puddled-iron furnaces, annealing furnaces, billet-heating furnaces and in furnaces producing malleable iron. Heating with this fuel is rapid and can be readily controlled. JLG(23)

Small Induction Furnaces for Laboratories. *Metallurgia*, Vol. 2, June 1930, pages 68–69.

Describes a small high frequency furnace developed by the Metropolitan-Vickers Electrical Co. An oscillator valve is used to produce frequencies up to 500,000 cycles. Charges up to ½ lb. can be melted in 2 to 3 minutes. A normal charge of 5 lbs. requires 20 – 30 minutes. JLG(23)

Economic Annealing Ovens. *Metallurgia*, Vol. 2, July 1930, page 84.

Regeneration applied to gas furnaces decreases gas consumption. Data on the gas required in annealing cast iron in a "Revergen" furnace made by Qualcast, Ltd. are given. With this furnace at 1000° C. the flue gases contain about 45% of the heat generated, but at the outlet of the regenerator they contain only about 5%. JLG(23)

Form of Furnace for Heat Treatment. Robert M. Keeney. *Metals & Alloys*, Vol. 1, July 1930, pages 589–594.

Uniformity of chamber temperature in a heat treating furnace depends upon the design of the furnace and method of heat utilization whatever the source of heat. Less skill is required to design a furnace offering relative uniformity of chamber temperature where electricity is used rather than other sources of heat. In poorly designed box type furnaces there may be a variation of 200° F. whereas the average will show variations of 35–60° F. when operating at 1500–1600° F. Direct firing should be used below 1900° and must be used above that temperature. Under-fired furnace yields greatest uniformity. The height of furnace is a much more difficult factor in temperature control than is the width. Relative uniformity of temperature in the electric furnace depends upon the arrangement of the heating elements, the uniformity of insulation of the furnace, elimination of excessive loss of heat at spots in the furnace by "through metal loss," that is, loss of heat through conduction of heat by parts of the furnace structure which may project into the chamber, and elimination of an excessive door loss. Uniformity is affected by improper loading. Care should be exercised to select a suitable type of furnace, for example tubing can be more satisfactorily annealed in a continuous furnace than a batch type furnace. A form of furnace and method of heat application suitable for high temperatures may not produce a uniformly heated product in a low temperature process as in tempering. Discussion is offered regarding the effect of furnace design, on rate of heating, time of exposure, temperature control and atmosphere of furnace. Data are presented regarding the effect upon over-all costs. ESC(23)

Studies on the New Furnace "Terni." (Gli studi che hanno condotoo alla realizzazione del Forno "Terni".) F. Fiorelli. *La Metallurgia Italiana*, Vol. 8, Aug. 1930, pages 770–773.

Discusses general characteristics of an open-hearth furnace especially the usual combustion in any open-hearth furnace. Then goes on describing particular feature of the new open-hearth furnace "Terni" built so that will give a better combustion of gases thus increasing the flame efficiency. GTM(23)

Some Remarks on Furnace Designs and Plant Layout. Walter Lister. *Metallurgia*, Vol. 2, Aug. 1930, pages 140–142.

The design of steel melting furnaces, including regenerators and valves is considered in some detail. Electric melting furnaces are also discussed. JLG(23)

Electric Furnaces for Heat Treatment. A. G. Lobley. *Electrical Review*, Vol. 106, April 11, 1930, pages 713–714; *Automobile Engineer*, Vol. 20, Mar. 1930, pages 110–111.

Paper read before meeting of Birmingham and Midland Section of the Society of Chemical Industry. MS(23)

The Poumay Cupola. John Cameron. *Foundry Trade Journal*, Vol. 42, May 8, 1930, pages 338–339, 340; May 22, 1930, pages 383, 384.

Includes discussion. Gives inventor's own explanation of the process. CO is burned to form CO_2 which is deliberately promoted in the melting zone. In other systems CO was considered harmful. Below the zone of fusion transformation of CO_2 into CO by two successive reactions takes place on account of the presence of incandescent coke at the level of tuyères $C + O_2 = CO_2$. CO_2 encounters the coke and is transformed into CO. Above the zone of fusion the CO is burned by the regenerative tuyères $CO + O = CO_2$. Compares it with the Greiner and Erpf system. Cupola using Poumay system contains less than one half the amount of FeO in slag of the ordinary cupola. Poumay cupola offers the following advantages: (1) Absence of oxidation between melting zone of the level of melting tuyères. (2) Reduction of S content. (3) Increased rate of melting. (4) Cleaner metal. (5) Reduction in loss of Si and Mn. Gives performance details. VSP(23)

REFRACTORIES & FURNACE MATERIALS (24)

New High-Refractory Materials. (Neuere hoch feuerfeste Stoffe.) Karl Becker. *Anzeiger für Hütten- und Maschinenwesen*, Vol. 52, Sept. 9, 1930, pages 5–6.

Describes a few materials suitable either as furnace lining or luminescent bodies which have a still higher melting point and a lower volatility than carbon, tungsten, tantalum or molybdenum. All these materials are carbides: tantalum-carbide melts at 4150° K, hafnium-carbide 4160°, zirconium-carbide 3805°, niobium-carbide 3770° K. A mixture of 4 parts tantalum-carbide to one part zirconium-carbide has a melting point of 4205° K., 4 parts tantalum-carbide to one part hafnium-carbide of 4215° K. At present, the great brittleness of these bodies prevents commercial application. Ha(24)

Refractories for Steel Works. (Eldfasta material i stalverk.) Kurd Endell. *Jernkontorets Annaler*, Vol. 114, July 1930, pages 336–355.

Summary of lectures given in Stockholm. Heat resistant materials are defined as those melting above Seger cone 26 corresponding to a temperature of 1530° C. The qualities to be examined are structure, chemical composition, porosity, specific gravity, melting point, deformation under load, swelling and expansion up to the highest operating temperature and brittleness with change in temperature. Qualities less readily examined, but important, are heat conductivity and resistance to slagging. A description is given of a bar press for measuring deformation under pressure, a furnace for measuring brittleness due to sudden temperatures and an apparatus for measuring coefficient of expansion. All these are obtained from Atom-Studiengesellschaft Berlin. It is concluded that the wearing qualities in use are determined not merely by the properties of the material but also by the conditions of operation. HCD(24)

Furnace Refractories for High Temperature Work. G. Junck. *Chemical Engineering & Mining Review*, Vol. 22, Aug. 5, 1930, pages 419–420.

An abstract of a paper read before the Society of Chemical Industry of Victoria. Three main classes of refractories are: (1) acid materials siliceous fireclays, ganister, etc. (2) neutral materials—chromite, graphite, silicon carbide, etc. (3) basic materials—dolomite, corundum, zirconia, etc. Fireclay is the most widely used refractory. Mullite refractories are made by heating clay and bauxite to 1600° C, obtaining the compound $3\,Al_2O_3\text{-}2SiO_2$. Mullite melts at 1850° C. and is highly resistant to abrasion and slagging by the usual fluxes. Pure sillimanite is the fused compound of a 50% SiO_2 and 50% Al_2O_3 mixture fusing at 1816° C. It has the very desirable property of remaining rigid to within a few degrees of its melting point. It is neutral, is highly resistant to spalling and has an exceptionally low coefficient of expansion. One of the latest developments is the electric furnace production of a synthetic spinel, by the fusion together of certain proportions of alumina and magnesia. The product is claimed to be exceptionally resistant to high temperatures, of high dielectric strength and of high heat conductivity. WHB(24)

GASES IN METALS (25)

Capacity of Iron to Absorb Hydrogen and Nitrogen. (Ueber die Fähigkeit des Eisens, Wasserstoff und Stickstoff aufzunehmen.) E. Martin. *Zeitschrift Verein deutscher Ingenieure*, Vol. 74, July 12, 1930, page 976.

The state of equilibrium in the absorption of hydrogen by pure electrolytic iron is very quickly reached; it takes nitrogen a little longer; while for oxygen 16 hours are required. Chromium absorbs less hydrogen than iron. Above 600° C. a nitride is formed with nitrogen. Molybdenum absorbs still less hydrogen and nitrogen than chromium. For 800° the hydrogen curve shows a maximum; nitrogen also shows a maximum near this temperature. When cooled under 800°, N was not liberated again. Tungsten absorbs neither H or N within the temperature range under test. 2 references. See *Metals & Alloys*, Vol. 1, Apr. 1930, page 479; Aug. 1930, page 684. Ha(25)

Solubility of Oxygen in Solid Iron. (Ueber die Löslichkeit des Sauerstoffs im festen Eisen.) W. Krings & J. Kempkens. *Zeitschrift für anorganische und allgemeine Chemie*, Vol. 183, Oct. 2, 1929, pages 225–250.

The Fe used was prepared by reduction of pure Fe_2O_3 in dry H_2 at 720–750°. The solubility of O_2 in this Fe was determined by means of equilibria experiments in a current of H_2-H_2O vapor at 715° and was found to be 0.11 ± 0.015%. The same experiments served for a study of the equilibrium $FeO + H_2 \rightleftharpoons Fe + H_2O$. (25)

Action of Carbonic Acid under High Pressures on Iron. (Ueber die Einwirkung von Kohlensäure unter hohem Druck auf metallisches Eisen.) Ernest Müller & Hans Henecka. *Zeitschrift für anorganische und allgemeine Chemie*, Vol. 181, June 28, 1929, pages 159–171.

Under high pressures of carbon dioxide, e. g., 20–50 atmospheres, carbonic acid reacts on aqueous suspensions of metallic iron to produce soluble ferrous hydrogen carbonate. As the concentration of the hydrogen carbonate ion increases, hydrogen-ion concentration of medium decreases and the rate of dissolution of iron approaches zero. (25)

Effects of oxygen, hydrogen and sulphur dioxide on the soundness of copper castings. See *Metals & Alloys*, Vol. 1, Sept. 1930, page 745. VSP(25)

Gases—Metals—Alloys. Smelting and Foundry Questions. (Gase—Metalle—Legierungen. Schmelzerei- und Giesserei-fragen.) WILLI CLAUS. *Giesserei*, Vol. 16, Oct. 18, 1929, pages 976–981; Oct. 25, 1929, pages 1000–1003.

Problems of melting and casting are taken up, among which are these: reversible and irreversible gas-dissolving phenomena in molten metals; law of solubility; gas separation; gas porosity as function of degree of saturation; speed of cooling; solidification and diffusion; deoxidation, desulphurization and decolorization. Bibliography given. (25)

Equilibrium Studies of the Reduction, Oxidation and Carbonization Processes of Iron. VIII. 9. The System Iron–Oxygen. (Gleichgewichtsuntersuchungen über die Reduktions-, Oxydations-, und Kohlungsvorgänge beim Eisen. VIII. 9. System Eisen-Sauerstoff.) RUDOLF SCHENCK, TH. DINGMANN, P. H. KIRSCHT & H. WESSELKOCK. *Zeitschrift für anorganische und allgemeine Chemie*, Vol. 182, Aug. 17, 1929, pages 97–117.

The object was to study the minima attained in the oxidation of Fe with small quantities of CO_2 and their dependence upon the O_2 content of the basic material. The O_2 saturation of the homogeneous oxyferrite phase at different temperatures was likewise determined. The metal used in the experiments was carefully freed of H_2 by many days heating in a high vacuum while the gas used was pure CO_2 gas under diminished pressure or, in a few cases, mixtures of CO_2 and CO. At 700° the reaction velocity was very slow, while at 1000° the stable zone was reached in the course of the first day. The stable Wüstite-oxyferrite equilibrium corresponds at 700° to a gas phase compound of 40.3% CO_2 and 59.7% CO, at 800° to 35.1% CO_2 and 64.9% CO and at 1000° to 28.5% CO_2 and 71.5% CO. At 800 and 1000°, the O_2 taken up in homogeneous solid solution is about 0.4%, the higher values previously obtained being due to the occurrence of the metastable Wüstite, low in Fe_3O_4. With mixtures of CO_2-CO, the relation between CO and CO_2 in the gas phase was determined along the stable Wüstite-oxyferrite boundary. The new values for maximum O_2 content require a diminution in the extent of the oxyferrite zone in the Fe-O equilibrium diagram. The possibility of preparing FeO in the pure state is discussed, and it is suggested that small additions of MgO or MnO would increase the stability of FeO. Addition of 0.5, 1.0 and 4.0% Cu as well as 4% Ni was studied, and resulted in a slight displacement of the Wüstite-oxyferrite border toward higher CO_2 concentration, as well as a more rapid attainment of the stable Wüstite-metal boundary. The solubility of O_2 is reduced more than 50%. (25)

INSPECTION (26)

Methods for the Identification of Aircraft Tubing of Plain Carbon Steel and Chromium Molybdenum Steel. W. H. MUTCHLER & R. W. BUZZARD (Bureau of Standards). *National Advisory Committee for Aeronautics, Technical Note* No. 350, Oct. 1930, Mimeographed, 27 pages. 27 references.

Shop tests for the routine inspection of aircraft tubing, to prevent mix-ups of carbon and Cr Mo tubing were examined. Chemical spot tests are so far not very promising. Magnetic examination is considered promising, but its practicability would require further investigation. Rockwell hardness testing as advocated by Knerr, is now in use, and meets some requirements. Spark testing is considered the most applicable. It is stated that the damage done in grinding for spot testing is negligible. (There would seem to be room for fatigue tests to establish this, abstractor.) The accuracy of the spark test in the hands of inexperienced operators is discussed, and details of the procedure given. HWG(26)

Spark Testing of Metals. *American Machinist*, Vol. 72, April 24, 1930, page 703.

Spark testing is a reliable and adaptable method of classifying slightly different steels, in checking mixed stocks, in testing decarburization depth and in determining the quality of metal in a weld. Applicable cheaply and rapidly to large quantities. Gives chart and table showing and describing the appearance of the sparks. These charts and tables are explained more fully in the text of the article. RHP(26)

EFFECT OF ELEMENTS ON METALS & ALLOYS (27)

Lead in Cast Brass and Bronze. H. C. DEWS. *Metallurgia*, Vol. 2, July 1930, pages 81–83.

Specifications for cast brass and bronze often require an unnecessarily low lead content. The effect of lead on the mechanical properties is dependent on the rate of cooling. The hardness of all brasses and bronzes is reduced by the addition of lead. As little as 0.5% lead improves the cutting properties, but further improvement is gained by increasing the lead up to 2%. JLG(27)

The Influence of Silicon Content and Cooling Speed on the Constitution of the Phosphide Eutectic in Cast Iron. (Der Einfluss des Siliziumgehaltes und der Abkühlungsgeschwindigkeit auf die Konstitution des Phosphideutektikums im Gusseisen.) P. BARDENHEUER & M. KÜNKELE. *Mitteilungen Kaiser Wilhelm Institut für Eisenforschung*, Vol. 12, *Report* No. 146 (1930), pages 33–38; *Stahl und Eisen*, Vol. 50, Aug. 21, 1930, page 1208.

Silicon and cooling speed have the largest bearing on crystallization of graphite. The influence of these 2 factors on the phosphide eutectic was therefore studied. Samples in wedge shape with an approximate content of 2% P and with increasing silicon content from 0.1–6% were examined. Up to 2% Si, the alloys contained, when poured in green sand, the ternary eutectic of phosphide. The pseudo binary eutectic appears at higher silicon content. Manganese up to 0.7% has no essential influence on this limit. The cooling velocity has only a small influence on the constitution of the phosphide eutectic. When the samples are poured into dry molds or molds heated up to 300° C. the formation of the pseudo binary eutectic already starts at 1.5% Si. This holds only for contents of phosphorus above 2%. For lower contents of phosphorus the ternary eutectic crystallizes also in higher silicon alloys. A higher carbon content favors the crystallization of the pseudo binary eutectic. GN(27)

Alloy Cast Irons. J. W. DONALDSON. *Metallurgia*, Vol. 2, July 1930, pages 103–104.

Contains bibliography of 17 references. Discusses effects of nickel, chromium and nickel plus chromium on gray iron. There has been little practical application of other elements in gray cast iron. JLG(27)

Effect of Certain Alloying Elements on Structure and Hardness of Aluminum Bronze. SELMA F. HERMANN & FRANK T. SISCO (Wright Field). *American Institute Mining & Metallurgical Engineers, Technical Publication* 365 (1930) 23 pages.

The effects of 5 different alloying elements on aluminum bronzes were determined by microscopic examination and in some cases hardness tests. The alloys contained 8, 10 and 12% aluminum with 1 and 5% alloying element. The 5 elements were nickel, iron, manganese, cobalt and silicon. With 5% nickel an additional phase was formed. Hardness results on the nickel alloys were erratic. Manganese shifted the equilibrium diagram to the left, i. e. it acted to increase the amount of aluminum. Iron had little effect on the microstructure, but decreased the grain size. Cobalt increased the hardness, had little effect on the grain size and shifted the diagram to the right. Silicon shifted the diagram to the left and greatly increased the hardness. All alloys containing 5% silicon were very brittle. Contains 3 references. JLG(27)

Copper-Base Alloys Containing Beryllium. (Ternäre, Beryllium enthaltende Legierungen auf Kupferbasis.) G. MASING & O. DAHL. *Wissenschaftliche Veröffentlichungen des Siemens-Konzern*, Vol. 8, No. 1 (1929) pages 202–210.

The addition of Be to α-solid solution alloys of Cu with Sn, Zn or Al causes them to undergo age-hardening after quenching from 700 – 800°. The presence of a third metal reduces the solid solubility of Be in Cu so that smaller quantities of Be are necessary to produce the maximum hardening than are required in the case of Cu. With α-brasses with a high Zn content a small addition of Be increases the hardness of the quenched alloy considerably and subsequent aging causes only a relatively small increase. Addition of less than 1% Al to the 2–2.5% Be-Cu alloys accelerates the age-hardening without intensifying the action. (27)

Aluminum-Beryllium Alloys with an Appendix on Silicon-Beryllium Alloys. (Berylliumhaltige Aluminiumlegierungen mit einem Anhang über Silizium-Berylliumlegierungen.) G. MASING & O. DAHL. *Wissenschaftliche Veröffentlichungen aus dem Siemens-Konzern*, Vol. 8, No. 1 (1929), pages 248–256.

The age-hardening properties of Cu-Al alloys are not improved by the addition of Be; Be cannot be used as a substitute for Mg in alloys of the type of aludur and aldrey. Si and Be form a eutectic with 39% Be, but not compounds or solid solutions. All the alloys are extremely hard and very brittle. (27)

The Decrease of Solution Speed of Zinc by Alloying with Cadmium. (Die Hemmung der Auflösungsgeschwindigkeit des Zinks durch Legieren mit Kadmium.) M. STRAUMANIS. *Zeitschrift für physikalische Chemie*, Vol. 6, Sec. A, June 1930, pages 112–124.

The solution speed of Zn-alloys with Pt, Ni and Fe is considerably, and those with Au and Cu extremely reduced by additions of Cd. In case of the alloy Zn-Au-Cd only 0.2% of Cd need be present to materially retard the dissolving of the alloy. The reasons accounting for the effect produced by Cd are established by studying single crystals of the alloys, and the formation of "layer-like" crystals during solidification of the melt is discussed. The order of metals cutting down the solution speed of Zn is as follows: Al, Mg, Pb, Te, Cd, Hg if a Zn-Au alloy is used. The protecting effect of Cd depends on the speed of solidification of the alloy. The elements Hg, Cd, Te and Pb alloyed with Zn do not accelerate the dissolution which is increased to a small extent by As and Ag. Zn does not form solid solutions with Cd, not even below 0.1% Cd. EF(27)

The Influence of Nickel and Chromium on the Properties of Malleable Iron. (Influence du nickel et du chrome sur les propriétés de la fonte malléable.) LEON THIERY. *Comptes Rendus*, Vol. 191, July 7, 1930, pages 47–49.

The properties of the cast iron of the composition C 3.15, Si 0.47, Mn 0.21, S 0.06, P 0.095 to which different amounts of Ni were added was studied before and after annealing corresponding to the malleabilizing cycle. The presence of Ni results in the precipitation of graphite on this treatment, the particle size of which is inversely proportional to the amount of Ni present, resulting in a fine structure much improving the physical properties, up to 2% Ni. A table of physical properties is given. JDG(27)

Copper Used in Special Structural Alloy Steels Developed in France. *American Metal Market*, Vol. 37, July 18, 1930, page 2.

Special structural steels are being manufactured in France to offset foreign competition. As a result of researches, the new steel has a chemical composition about as follows: chromium 0.4–0.6%, copper 0.3-0.5%, sulphur 0.06% maximum, and phosphorus 0.07% maximum. It is mechanically about 1½ times stronger than ordinary structural steel. This steel offers no special difficulty in rolling of bars and possesses great homogeneity throughout the bar and conserves the general properties of mild steel. It can be cut, punched and worked either hot or cold with ease in conditions comparable with those of mild steel WHB(27)

Report of Research Committee on the Effect of Tin and Arsenic on High-Speed Tool Steel. *Reprint Proceedings American Society for Testing Materials*, Vol. 29, Part I (1929) 5 pages.

This report gives the composition of various high-speed steels and results of the testing of 2 types which show, among other things, arsenic and tin in amounts of 0.50% in high-speed steel noticeably embrittle the steel. The hardness of annealed steel is comparable to that of regular high-speed grade. (27)

Silicon Brasses. *Metallurgist*, June 1930, pages 95–96.

An extended abstract of the article by H. W. Gould and K. W. Ray in *Metals & Alloys*, Vol. 1, April, 1930, pages 455–457; May, 1930, pages 502–507. See abstract in *Metals & Alloys*, Vol. 1, Aug. 1930, pages 685. VVK(27)

The Influence of Nickel and Manganese on the Properties of High Speed Steels. (Ueber den Einfluss von Nickel und Mangan auf die Eigenschaften von Schnelldrehstahl. Ein Beitrag zur Klärung der Anlassvorgänge im Schnelldrehstahl sowie seiner Eigenart als warmfester Stahl.) V. EHMCKE. *Archiv für Eisenhüttenwesen*, Vol. 4, July 1930, pages 23–35; *Stahl und Eisen*, Vol. 50, Aug. 7, 1930, pages 1131–1132. 17 references.

The fact that stability against drawing as well as hardness at elevated temperatures of a hardened high speed steel are favorably influenced by an increasing quenching temperature (increasing amount of austenite) lead to this investigation which covers common high speed steels with nickel contents of 2 to 15%. For comparison a common nickel-free high speed steel and a 10% straight nickel steel were examined. Hardness and annealing tests show that the hardness decreases with increasing nickel content. Steels with 5% and more nickel are austenitic when quenched from high temperatures, therefore giving rather low hardness numbers (300 Brinell and lower). In annealing between 600 and 900°C. the austenite is decomposed to martensite thus increasing the hardness to 575 Brinell for the 5% nickel high speed steel. Manganese high speed steels are similar to nickel high speed steels. Dilatometric measurements were carried on which prove that the transformation austenite to martensite in Ni high speed steels takes place during cooling within a critical range. This temperature range is 700 to 900° C. for the 5% and more Ni steel, around 600° C. for a 3% Ni steel. The decomposition taking place at these temperatures (secondary hardness) essentially results in a precipitation of carbides which has its bearing on the stability of the austenite. Martensite crystallizes, therefore, in cooling Ni- and Mn high speed steels in the martensitic state offer no increased stability toward annealing compared with common high speed steels. Dynamic and static hardness tests and hot tensile tests were carried on to determine the hot tensile properties in relation to the nickel content. The tests show that hardness and tensile strength up to 600 and 700° C. are lower than those of a regular high speed steel. At still higher temperatures, however, nickel alloy steels are superior to nickel-free high speed steels. An austenitic manganese high speed steel is absolutely similar to the nickel steel as regards hot tensile properties. This proves that the austenitic state determines the superior hot tensile properties in the temperature range above 650° C. GN(27)

The Effect of Silicon on the Transformation Points and the Structure of High Chromium Steels. TAKEJIRO MURAKAMI & KINJI YOKOYAMA. *Kinzoku no Kenkyu*, Vol. 7, Sept. 20, 1930, pages 451–466.

Using 20 specimens containing about 0.3% C and ranging from 9 to 16% Cr and less than 3% of Si, the effect of Si on the transformation points and the structure of high Cr steels was studied. The A_2 point was determined by magnetic analysis; the result is shown in an isothermal diagram, Fig. 1, for the A_2 point from which we see that the A_2 point is lowered with increasing

Si and Cr contents. The A_3 and A_1 points were determined by measuring the thermal dilatation during heating and cooling at very slow rate. As the Si and Cr contents increases, these transformations decrease in magnitude until these vanish, the temperatures of the changes being raised. Fig. 2 shows the isothermal diagram for the starting point of the Ac_1 change in these specimens. The microstructures of the specimens, annealed or quenched from several temperatures were observed, and several sectional diagrams with constant Si or Cr content, and isothermal diagrams were constructed, in which the change of structure due to the change of compositions or temperatures is clearly demonstrated. By adding silicon up to

3%, no special structural constituent is observable, the silicon being dissolved in the iron. The composition range of alloys consisting of the γ-phase alone at high temperature extends toward high chromium content as the Si content increases. The carbon content at the eutectoid composition decreases by adding Si. TM(27)

Effects of Nickel upon Malleable Cast Iron. *Metallurgia*, Vol. 2, June 1930, pages 67–68.

The effects of up to 3 or 3.5% Ni on the mechanical properties of white-heat malleable castings have been determined by J. V. Murray. The castings were made both from cupola and crucible melted iron. Ni when added in amounts up to 1% increases the tensile strength. Generally the addition of nickel lowers the elongation and the bending angle. The best mechanical properties were obtained with 1% Ni. A cupola melted iron containing no Ni had a tensile strength of 21.3 tons/in.², an elongation of 6.5%, and bent 67°. A similar iron containing 1% Ni had a tensile strength of 25.4 tons/in.², an elongation of 4.5%, and bent 33°. JLG(27)

Special Steels. *Mining Journal*, Vol. 169, June 28, 1930, pages 17–18, 20.

A discussion of the effect of the addition of various amounts of other metals on the properties of steel and the chief uses for the resulting products. AHE(27)

The Use of Vanadium in Metallurgical Industry. (Memoire sur l'emploi du Vanadium dans l'industrie siderurgique.) E. B. SAKLATWALLA, J. STRAUSS, H. CHANDLER & G. NORRIS. *Aciers Speciaux, Métaux et alliages*, Vol. 5, Sept. 1930, pages 390–406.

Ferro-vanadium generally used in United States contains 35–45% vanadium, and that used in Europe 45–55%. Ferro-vanadium containing 35–45% vanadium melts at 1425° C. and easily soluble in molten steel. Ferro-vanadium can be added in crucible with the charge; in electric furnace, about 15 minutes before tapping; in open-hearth, to the ladle. There is a recovery of 95–100% in electric furnace and crucible process, and 85–95% in the open-hearth. Vanadium produces a fine structure in steel, with less tendency for dendritic segregation. Typical vanadium steel contains 0.10–1.05% carbon and 0.15–0.18% vanadium, while in tool steel vanadium content varies from 0.20 to 1.00%. The effect of vanadium steel is emphasized by the proper heat treatment. Steels used for construction purposes contain Ni, Mn, Mo, Si or Cr besides carbon and vanadium. GTM(27)

INSTRUMENTS & CONTROLLERS (28)

The Determination of the Calorific Value of Coke Oven Gas in the Junker Calorimeter. (Die Heizwertbestimmung von Koksofengas mit dem Junker'schen Heizwertmesser.) H. GREWE. *Archiv für Eisenhüttenwesen*, Vol. 4, Aug. 1930, pages 75–85; *Stahl und Eisen*, Vol. 50, Sept. 4, 1930, pages 1269–1270.

Report 77 of the Chemical Committee of the Verein deutscher Eisenhüttenleute. The general principles for the determination of the calorific value of gases are outlined. These are: (1) gas, combustion air and waste gas must have the same temperature; (2) gas, combustion air and waste gas must be completely saturated with water vapor; (3) the vaporization heat of the contraction water must be subtracted from the upper calorific value. Junker's Calorimeter can be easily equipped with a device for moistening the combustion air, thus fulfilling the above outlined requirements. New devices for moistening the air and cooling the waste gases have been designed and described. A new device has, furthermore, been constructed for a reliable checking of the gas quantity to be burned. GN(28)

Apparatus for Electroplating Solution Control. *Brass World*, Vol. 26, July 1930, pages 191–192.

Eimer & Amend, N. Y. City have marketed the Pitschner electroplating outfit which is an apparatus for electrometric control of nickel plating solutions. Its installation and operation are described. WHB(28)

Chromic Acid Determination Outfit. *Brass World*, Vol. 26, Aug. 1930, page 213.

The Kocour Co., Chicago, Ill. offers a simple apparatus for determining the chromic acid content of a plating solution. The method involves the permanganate-ferrous sulphate titration, and provides direct readings in ounces per gallon. The outfit is illustrated. WHB(28)

A New Portable Immersion Pyrometer. *Instruments*, Vol. 3, No. 7, July 1930, pages 478–479.

A "cave" type thermometer enclosed in a sheath of low thermal lag and equipped with self-contained indicator handle is described for use in obtaining pouring temperatures. Manufactured by Illinois Testing Laboratories, Inc. WHK(28)

Comparison of Fused Silica, Gold and Platinum Linings for Calorimeter Bombs. OSCAR KENNETH BATES. *Industrial & Engineering Chemistry, Analytical Edition*, Vol. 2, April 15, 1930, pages 162–164.

The heating values of the different coals as determined by the Emerson bomb lined with vitreosil agreed very closely with those determined using a platinum lined bomb. The values obtained with the bomb lined with gold backed by silver agreed satisfactorily with the vitreosil lining for low sulphur content samples, but differed when samples of high sulphur content were used. This indicates that additional heat is evolved by reactions in which the lining plays the important part. This additional heat was not evolved when the vitreosil and platinum linings were used. MEH(28)

A Temperature Controller at McGill University. GORDON SPROULE *Metals & Alloys*, Vol. 1, June 1930, pages 554–555.

The work requiring annealing of malleable cast iron by students has been improved and facilitated through the design of an attachment for a Leeds and Northrup potentiometer recorder to make it control the tool type Hump furnace in which the annealing was carried out. The attachment is described. ESC(28)

Measurement of Corrosion with the "Corrosimeter" of Dr. Toedt. (Die Messung der Korrosion (Rostens von Metallen) mit dem Korrosimeter nach Dr. Tödt.) G. GOLLNOW. *Zeitschrift für Feinmechanik und Präzision*, Vol. 38, Aug. 31, 1930, pages 2–4; *Chemiker Zeitung*, Vol. 54, Feb. 5, 1930, page 110.

The instrument is based on the fact that by placing the sample and a nobler metal together in a water solution and connecting them through a galvanometer, the current then flowing gives a direct measure for the amount of corrosion going on under the prevailing condition. As usually the corrosion is expressed by the loss of weight in g./day and surface. The instrument is calibrated directly in loss of weight in g. The very simple arrangement is described in detail. The Strength of Steels at High Temperatures. HOUDREMONT & EHMCKE. *Metallurgist*, Oct. 1929, pages 155–156.

The authors have taken as a basis of comparison tensile strength as determined in tests occupying 15 to 20 minutes. Considering first the lower temperature region, it has been shown that proportionality exists for steels of pearlitic nature between creep strength at 500° C. and yield point at room temperature. (29)

Working Stresses for Steel at High Temperatures. D. S. JACOBUS. *Advance Paper* No. 22, *American Society of Mechanical Engineers*, Dec. 2–6, 1929, 5 pages.

The results of practical experience set the maximum working stresses up to temperatures of 800° F. Above this, working stresses are scaled down in proportion to falling off of stresses producing creep. The first curve of creep points published by J. J. French is used and the working stresses for given temperatures are taken at ²/₃ creep-point stress. The effect on stress of piercing boiler shell with holes and of transmitting heat through equalization of stress through extension of most-strained fiber is discussed. (29)

Physical Properties of Boiler Sheets at Elevated Temperatures, with Special Reference to the Relation between Hot Yield Point and Tensile Strength at Room Temperature. (Festigkeitseigenschaften von Kesselblechen bei erhöhten Temperaturen, mit besonderer Berücksichtigung des Verhältnisses der Warmstreckgrenze zur Zugfestigkeit beim Raumtemperatur.) F. KÖRBER & A. POMP. *Mitteilungen Kaiser Wilhelm Institut für Eisenforschung*, Vol. 12, *Report* No. 144 (1930) pages 13–22.

Four types of boiler sheets, with carbon contents between 0.08% and 0.24%, manganese between 0.36% and 0.66% and partly containing silicon were tested at room temperature, 300° C., 350° C., 400° C. and 500° C. It was found in accordance with former investigations that there is a relation between hot yield point and tensile strength at room temperature, so that the yield point at higher temperatures up to 500° C. can be approximately calculated from the tensile strength at room temperature. GN(29)

Contribution to the Knowledge of Graphite Precipitation in Cast Iron and its Effects. (Beiträge zur Kenntnis der Graphitabscheidung im Gusseisen und deren Auswirkungen.) E. PACK. *Dr.-Ing. Thesis, Technische Hoch Stuttschulegart* (1927) 88 pages.

Pack's investigation on the influence of superheating temperature and cooling velocity on the graphite crystallization pertains to a subject which has interested the cast iron foundryman for a number of years. The influence of the mentioned factors on the graphite crystallization has been studied by other investigators before Pack, so that it is of interest to know how his results check with these. The author studied the problem from a standpoint which guaranteed an absolutely uninfluenced process of crystallization. For this reason the melted samples were not cast in molds or quenched but cooled in the crucible. The tests cover two groups. In the first group the carbon content was kept constant whereas the silicon content was gradually changed from 0.5 to 3%. The second group covers experiments with cast irons of constant silicon content around 3% and varied carbon content from 3.0–1.5%. The statement that an increasing temperature of superheating refines the graphite as well as the findings on the change of the eutectic temperature with increasing superheating temperature are in agreement with Piwowarsky's results. On the other hand, Piwowarsky's findings on the course of the curve for combined carbon in relation to superheating could not be confirmed; these curves showed an irregular course which is due, according to the author's opinion, to the crystallization of primary graphite which decreases the amount of eutectic graphite. The theory and results of Hanemann, too, are only partly confirmed. Contradictory to Hanemann, the crystallization of eutectic graphite was found to be independent of the cooling rate. Some tests on shrinkage and abrasion are included, which illustrate the importance of the graphite size on the characteristics of cast iron. GN(29)

Permanence of Dimensions under Stress at Elevated Temperatures. W. H. HATFIELD (Brown-Firth Research Laboratories). *Iron & Steel Institute, Advance Copy* No. 2, Sept. 1930, 18 pages; *Engineer*, Vol. 150, Sept. 16, 1930, page 345.

Contains bibliography of 35 references. Engineering experience has proved, that for practical purposes, permanence of dimensions is attained within measurable accuracy over long periods of time at atmospheric temperature. An attempt has been made to determine the stress below which permanence of dimensions will attain at elevated temperatures for various steels. The value "time-yield," proposed by the author, is the stress within which, at the given temperature, stability of dimensions is attained within a period of 24 hours for a further period of 48 hours; the extension not to exceed the elastic deformation of 0.5% and with limitation as regards measurements of permanence of dimensions of the order of one millionth of an inch per hour. The author considers that a safe stress, for designing purposes, is two-thirds of the time-yield. Time-yield values for temperatures from 300 to 700° C. are given both for carbon and alloy steels. With carbon and low alloy steels no outstanding values were obtained. None of these steels had a value of over 3 tons/in.^{2} at 550° C. At 500° C. a Ni-Cr-Mo-V steel showed some merit. In the highly alloyed steels a Ni-Cr-W alloy had high time-yield values, giving 12.6 tons at 400° C. Die and high speed steels did not have high values. The time-yield values obtained together with the chemical analyses of the steels are given in tables. LFM+JLG(29)

LEACHING (30)

Innovations in Copper Leaching Employing Ferric Sulphate-Sulphuric Acid. HARMON E. KEYES. *Bulletin* 321, *United States Bureau of Mines*, 1930, 67 pages.

Autoxidation of ferrous sulphate and sulphur dioxide in the presence of air forms ferric sulphate and sulphuric acid. The ferrous sulphate comes from discard solutions; the sulphur dioxide comes from pyrite, sulphur or roaster gases. Iron is first oxidized; then sulphuric acid is produced. Most copper minerals dissolve in this reagent (chalcopyrite and certain silicates are exceptions). The complete process, from acid making to copper precipitation, was successfully carried out on a test-plant scale on a number of ores. No soluble impurities were found which prevented regeneration of the barren solutions. Plant results are given The mechanism of percolation leaching was also studied. In flood leaching the fines cause channeling, which lowers extraction. This effect can be minimized by agglomeration of the charge before leaching. The fine particles are made to adhere to larger particles, the glomerule behaving as a large particle and the solution passing easily. (Includes 27 footnote and bibliographic references.) AHE(30)

Methods and Costs of Treatment at the Calumet and Hecla Reclamation Plant. C. HARRY BENEDICT. *Information Circular* 6357, *United States Bureau of Mines*, September 1930, 11 pages.

Tailing dumps are being reworked by leaching (80%) and flotation (20%) to recover 90% of the copper in the dumps. This results in a total recovery of 95% of the metal in the ore. In 1929, heads assayed 0.973% copper, tails 0.120%. Almost 26,000,000 pounds of copper were produced, 16.81 lbs./ton treated, at a cost of 2.94 cents per pound of copper and 49.5 cents per ton of material dredged. This was divided as follows (in cents): administration 3.8, dredge and pontoons 5.6, shore plant and belt conveyor 2.5, regrinding 17.2, leaching 17.8, flotation 1.8 and miscellaneous 0.8. AHE(30)

Investigations on the Dressing of Raw Beryl and on the Production of Beryllium Salts Suitable for Electrolysis. (Versuche zum Aufschluss des Rohberylls und zur Herstellung geeigneter Berylliumsalze für die Elektrolyse.) K. ILLIG, M. HOSENFELD & H. FISCHER. *Wissenschaftliche Veröffentlichungen des Siemens-Konzern*, Vol. 8, No. 1 (1929) pages 30–41.

For the large-scale preparation of Be compounds from beryl the most satisfactory method comprises heating an intimate mixture of the finely powdered mineral with an equal weight of Na_2SiF_6 for several hours at 650° and leaching the product with cold water. Extraction of over 90% of the beryllia accompanied by a little Fe and only traces of Al is thus readily effected. A higher temperature results in fusion of the mass and a lower extraction. Evaporation of the leach liquors gives a crop of large crystals of Na fluoberyllate, Na_2BeF_4, which are purified by dissolving in water, bubbling air through the liquor to remove Fe, and again crystallizing. Practically the whole of the Be may be recovered by saturating the mother liquors with NaF. Complete precipitation of beryllia from fluoberyllate solutions by NH_3 is obtained only by using a ten-fold excess; additions of a slight excess of lime, however, effects complete precipitation of the hydroxide in a granular form. The washed precipitate is treated with HF and the residual CaF_2 removed by decantation. The solution is evaporated to dryness on the water bath and the residue heated at 150°, whereby the oxyfluoride, $2BeO.BeF_2$, is obtained. Extraction of the residue with an equal weight of hot water dissolves all the oxyfluoride, leaving NaF and CaF_2 insoluble. Evaporation of the filtered solution affords the pure salt as a snow-white powder; mixed with barium fluoberyllate the salt forms a readily fusible electrolytic bath for the production of the metal. Methods are also described for the preparation of the double fluorides, $NaBeF_3$, $BaBeF_4$ and $BaBe_2F_6$. 19 references. (30)

REDUCTION METALLURGY (31)

Some Remarks on the Reactivity of Metallurgical Coke. (Note sur la reactivite des cokes metallurgiques.) DUFRAINE. *Revue de Metallurgie*, Vol. 27, Sept. 1930, pages 509–511.

The reactivity of coke (its capability to react with CO_2) is inducive to high blast furnace efficiency. Considerations are advanced to prove this point. The determination of the change of reactivity on account of the presence of non-organic substances in the coke was made by soaking different cokes in watery suspensions of cement, a mixture of cement with iron ore and a mixture of cement with limestone, which was followed by drying and heating in an electric furnace at different temperatures. Analysis of the gases produced showed that the treatment reduces the reactivity of the coke. JDG(31)

The Gas Distribution in the Blast Furnace Shaft. (Beitrag zur Frage der Gasverteilung im Hochofenschacht.) J. STOECKER & H. CORNELIUS. *Stahl und Eisen*, Vol. 50, Aug. 28, 1930, pages 1217–1221. 4 references.

Report 114 of the Blast Furnace Committee of the Verein deutscher Eisenhüttenleute. Composition, temperature, pressure and velocity of blast furnace gases were measured in the upper part of the shaft. The measurements were taken at locations at various distances between wall and center of the furnace. The results lead to the conclusion, at least as far as the examined furnace is concerned, that the charge is less dense near the wall and in the center of the furnace than in the ring-like zone between wall and center The denser sections in the charge show increased indirect reduction as indicated by a lower temperature and lower content of carbon monoxide. Experiments to determine the volumetric distribution of the gas over various furnace sections have not been successful. GN(31)

The Modern Blast Furnace and Its Operation. R. A. HACKING. *Metallurgia*, Vol. 2, May 1930, pages 27–28; July 1930, pages 99–100, 104.

The amount of air entering the blast furnace is about 5.8 times the weight of carbon burned. Increasing air-blast temperature has the following effects: (1) the additional sensible heat of the blast is added without increased amounts of material, which theoretically raises the temperature in the combustion zone, (2) the speed of reaction is increased, thereby decreasing the dimensions of the combustion zone, (3) the number of thermal units added per unit of carbon burned is increased. The chief reason for economy of the hot blast lies in the intensity of temperature in the hearth. The limit of air-blast temperatures lies at about 1150° F. with basic iron using ungraded ores, and about 1400° F. in the case of foundry and hematite practice. The use of bosh tuyères is discussed. Water vapor in the blast reduces the temperature in the combustion zone due to the endothermic reaction of water vapor with carbon. Theoretically each grain of water per cubic foot of air lowers the temperature 23 or 27° F. Increase in moisture content of 3 gr./cu. ft. has the same effect as lowering the blast temperature 80 or 90° F. The blast can be dried either by absorption or refrigeration. Refrigeration has been abandoned as uneconomical. Recently drying with silica gel has been applied at the Wishaw plant of the Glasgow Iron and Steel Co., with an increase in output of 13% and a decrease in fuel consumption of 5%. It is probably more economical to increase the blast temperature than to dry the blast. Contains 2 references. JLG(31)

The Thermal Reduction of Beryllium. (Herstellung von Beryllium auf thermischen Wege.) K. ILLIG & M. HOSENFELD. *Wissenschaftliche Veröffentlichungen aus dem Siemens-Konzern*, Vol. 8, No. 1 (1929) pages 26–29, 20 references.

Brief descriptions of the known methods for the production of beryllium. This article is only of historical value as beryllium cannot be produced commercially by any of the methods described. (31)

Sponge Iron and Its Relation to the Steel Industry. EDWARD P. BARRETT. *Mining & Metallurgy*, Vol. 11, Aug. 1930, pages 395–396.

It is questionable whether or not high-grade sponge Fe can be produced from low-grade materials. Sponge Fe containing small amounts of S can only be made from raw materials containing small amounts of S or by some special process in which S is removed from reducing gases prior to their contact with Fe_2O_3. There are many variables in making estimate of the cost of producing sponge iron. They are: raw materials, plant and operation. Gives an abstract of Rohland's paper which was abstracted in *Metals & Alloys*, Feb. 1930, page 390, on experiments with sponge Fe. VSP(31)

Rolling Process for Production of Metals. (Das Wälzverfahren zum Gewinnen von Metallen.) R. HOFFMANN. *Zeitschrift Verein deutscher Ingenieure*, Vol. 72, July 26, 1930, pages 1041–1048.

A process for obtaining metals or alloys from ores, which has gained a very wide application since 1924, consists in the following: the raw material mixed with fuel and eventually other additions are charged dry or wet on one end of a slightly inclined drum, and progress uniformly through the furnace; and the necessary air passed through the drum in a counter-current. As the material is forced by the rotation of the drum, to roll over and over continually, this process is called the rolling process. The raw-materials which are particularly suitable for this process are zinc and lead ores, residues and ashes of brass, electrolytes and poor ores. The paper describes in detail equipment, chemical and metallurgical behavior of the different materials and gives operating data. The author believes this method to be very promising. Ha(31)

What Reasons Compelled the Prague Ironworks Company to Introduce Thin-Walled Blast-Furnaces? JINDRICH SAREK. *Iron & Steel Institute, Advance Copy* No. 7, Sept. 1930, 33 pages; *Engineer*, Vol. 150, Sept. 26, 1930, pages 344–345; *Engineering*, Vol. 130, Sept. 19, 1930, pages 371–372.

There are now 4 thin-walled blast furnaces in operation at the Prague Ironworks, and one more being installed. The furnaces operate on lean ores, and have been very satisfactory. The operation of the blast-furnace is discussed in some detail. Two different modes of blast-furnace working are described as internal and external. Coke consumption has been lessened by the thin-walled furnaces, and the linings have worn uniformly. LFM+JLG(31)

The Modern Blast Furnace and Its Operation. Part V. R. A. HACKING *Metallurgia*, Vol. 2, Sept. 1930, pages 177–178.

This article covers: the use of oxygen enriched blast, theoretical consideration, future possibilities, effect of increased blast pressure influence of increased blast velocity and practical considerations. It was observed that each one percent increase by weight in the oxygen content of the blast raises theoretical temperature of combustion by approximately 125° F., and reduces the moisture content by 5 grains/cubic foot. It is stated that enrichment up to 25% of oxygen enabled the stoves to be dispensed with, and a higher grade of pig iron to be produced. GTM(31)

Zinc Smelting from a Chemical and Thermodynamic Viewpoint. C. G. MAIER. *Bulletin* 324, *United States Bureau of Mines* (1930) 93 pages.

This paper shows in detail the application of newly recalculated theoretical data (especially thermodynamic) to the general chemistry of zinc reduction. The free energy of formation of zinc oxide was obtained by four independent methods. Chapter headings are: thermodynamic properties of zinc and its compounds; zinc oxide and carbon; direct smelting for liquid zinc and the zinc blast furnace; a thermally ideal zinc-smelting cycle; reoxidation and blue-powder formation; methane as reducer for zinc oxide; and zinc sulphide in smelting. (Includes 130 footnote references.) AHE(31)

Bulldog Slag as Related to Steel. WILLIAM H. STEVENS. *Iron Age*, Vol. 125, May 15, 1930, pages 1457–1458.

Author claims that 99% of slag is used to flux earthy materials out of furnaces. Injurious elements and their compounds enter the metal in the reduction zone in blast furnace. Finished products depend on the influence which C has on oxides, silicates, sulphides, gases and mechanical properties. Correct filling of furnace is necessary, for quality and quantity depend on it. Standard bell distribution gives an ideal filling for American practice, and brings amount of wind required at the tuyères. Large and porous grain structure, heavy cinder and bulldog slag inclusions are also in evidence. Gases following limy furnace pig iron cannot be removed by deoxidizing agents. Corrosion may get its start from this type of pig iron. Hot blast cannot pierce viscous slag. Pig iron resulting is clean, free from scum, fast running and has low graphite content. It meets both chemical and physical requirements. VSP(31)

Charcoal Blast-Furnace Practice in Mysore. B. VISWANTH. *Mining & Metallurgy*, Vol. 11, July 1930, pages 332–335.

Gives details of plant construction and operation of the Mysore Iron Works at Bhadravate, British India. The blast furnace is built of steel plates and lined with fire brick. The hearth is cooled by means of cast Fe plates with wrought Fe cooling pipes cast in them. There are 6 tuyères, and each is surrounded by a Cu cooler. The bosh is thin lined. There are 4 stoves 14 ft. in diameter and 65 ft. 8 in. high. They are of side combustion and two-pass type. Temperature varies from 700 to 1000°F. Charcoal is used as fuel. The principal ore deposit is a mixture of limonite and hematite. Most interesting feature is the peculiarity of the slags. This is probably one of the few furnaces running on high alumina slag. VSP(31)

Sintering of Blast Furnace Dust and Treatment of Carbonate Iron Ores by Greenawalt Method. (Agglomeration des poussieres de hauts fourneaux et traitement des minerais de fer carbonates par le proceded "Greenawalt".) ROBERT CORDONNIER. *Revue de Metallurgie*, Vol. 27, Sept. 1930, pages 467–478.

A description of a sintering installation of Greenawalt design for treatment of carbonate ores of Fe installed at Societe Auxiliaire des Mines des Pyrenees-Orientales at Vernet-les-Bains and the principles involved in its operation. The method eliminates from the core CO_2, H_2O and volatile metals like Zn, As, Sb. Sulphur content is reduced very considerably. JDG(31)

Roasting of Chromite Ores to Produce Chromates. A Study of Effects of Various Reagents and Impurities on Oxidation Reactions. H. A. DOERNER. *Report of Investigations* 2999, June 1930, *United States Bureau of Mines*, 30 pages, 24 references.

When Cr_2O_3 is mixed with excess lime and heated above 800° it reacts to form an insoluble calcium chromite, which is readily oxidized by air to form calcium chromate. This in turn partly decomposes into acid-soluble calcium chromic-chromates of uncertain and perhaps variable composition. The highest conversion to chromate was 75% at 850°. Under similar conditions magnesia reacts to form a brown insoluble chromite, only a small portion of which oxidized to a water-soluble chromate. No acid-soluble decomposition products were found. Over 90% conversion to chromate was obtained by roasting a mixture of equal parts of lime, magnesia and Cr_2O_3 at 850°. Fine grinding, intimate mixing and either wetting or thorough rabbling during the roast are necessary for good results by this method. Roasting 1 part Cr_2O_3, 1.8 parts sodium sulphate and 3 parts lime at 850° gave over 90% conversion to chromate. There was no reaction with Cr_2O_3 and sodium sulphate alone. Dolomite is as effective as limestone. Complete replacement of lime by magnesia gave poor results. Roasting Cr_2O_3 and sodium carbonate gave sodium chromate. Addition of lime promotes the reaction. Practically complete conversion was obtained from a mixture of 2 parts lime, 1.4 parts sodium carbonate and 1 part Cr_2O_3 roasted at 850 to 1070°. Lime can be replaced by dolomite or a mixture of magnesia and Fe_2O_3. Use of the latter required higher temperatures and gave lower conversion. Of the common impurities found in chromite ores, magnesia appears to be beneficial or harmless, alumina has little effect unless alkali salts are absent, and silica is the most objectionable, tending to prevent oxidation of the chrome. AHE(31)

NON-METALLIC COATINGS FOR METALS (32)

Protective Coatings for Iron and Steel. Part II. Paints and Enamels. HENRY N. BASSETT. *Industrial Chemist*, Vol. 6, July 1930, pages 293–297.

The author discusses first the methods of cleaning the surface: (*a*) pickling, (*b*) scruffing, (*c*) sand-blasting, (*d*) use of patent rust removers. He then takes up in some detail the various coatings, discussing the composition and uses of the different enamels, paints, lacquers, enamels with varnish bases, and Japans, as well as the cheaper coatings designed to give partial protection, such as slaked lime in solvent naptha and tallow in trichlorethylene. MPB(32)

Influence of Sea-Water on Paint Coatings. (Einflüsse des Seewassers auf Anstriche.) BÄRENFÜNGER. *Zeitschrift Verein deutscher Ingenieure*, Vol. 74, March 22, 1930, pages 373–375.

General remarks on damage by corrosion and protective coats. Of all coatings red lead has been shown to be the most satisfactory as it adheres very firmly to iron; care must be taken, however, to use an oil which does not absorb water. The influence of sea water on several paints is shown in photographs, some of them in natural colors. 3 References Ha(32)

Enamelled Hardware. DR. STANLEY SMITH. *Sheet Metal Industries*, Vol. 3, VI, Feb. 1930, page 573; VII, Apr. 1930, pages 297–298.

To achieve the necessary fine coating of ground enamel, it should be diluted with about 40% of water, and so fired that a bend test will not peel off this primary coat. The primary coat should be dried as rapidly as possible. The white enamel coatings should be dried cautiously, preferably in hot air. The average weight of enamel on a piece is 25–30% of the weight of the metal. Burning temperatures and their effect on stannic oxide in the enamel are discussed. Ground enamel burned in at 950–1000° C.; white and blue coating fired at 800–850° C. A short list of rules governing enamelling operations is given. Common enamel defects and their causes are set forth. AWM(32)

Japanning and Enamelling Sheet Metal Ware. "ARGENT." *Sheet Metal Industries*, Vol. 4, June 1930, pages 120–121.

A stove with jets outside the japanning chamber in a flue running around it is recommended. Close thermometer check of temperature is essential to good work. Observing correct time of stoving is absolutely necessary to insure good finish. AWM(32)

Japanning and Enamelling Sheet Metal-ware. II. ARGENT. *Sheet Metal Industries*, Vol. 4, Sept. 1930, page 394.

Freedom from dust in the japanning shop is stressed and means of obtaining this condition are mentioned, i. e., doors and windows doubled, ventilation by means of wall inlets and outlets, white tiled walls, etc. The desirability of a regulated temperature in this room, which should not fall below 65° F., is shown. The preparation of colored japans and the stoving of these is discussed. It is recommended that the preparation of these japans be left to the specialist rather than being attempted by the sheet metal worker. AWM(32)

FOR SALE: LEITZ MICRO-METALLOGRAPH

You can now purchase at a very attractive price, a used Leitz Micro-Metallograph of recent design, complete with all accessories, in perfect working condition.

Address Box 1-1-31, care METALS & ALLOYS

Corrosion-Ometer
for Accelerating and Measuring
» CORROSIVE EFFECTS ON «
METALS AND ALLOYS

Industrial Metallurgy today finds one of its most serious problems in the corrosive action of the elements upon metals and their various alloys. Reagents of various kinds used in manufacture offer equal difficulties. The choice of a metal or alloy for a given purpose often depends upon an accurate, accelerated determination of the corrosion resistance factor. And such measure must be expressed in terms of world wide acceptance that are independent of location, season, and other local, modifying conditions.

Weather-Ometer is the only equipment known today to the industrial scientist that meets all these requirements. Its use in making analysis and records of this nature is constantly increasing. We will gladly furnish you complete details of studies of this kind now being conducted and our engineering department will co-operate with you regarding your special needs.

Write today for complete details regarding Weather-Ometer and its uses. Ask for Bulletin MA-1.

Fire Clay Refractories Picture Film

In 1923 under the direction of the United States Bureau of Mines and in coöperation with the Laclede Christy Clay Products Company, a motion picture "Fire Clay Refractories" was produced. It has recently been revised to include improvements that have taken place, such as the modern method of burning refractories by tunnel kilns, and use of improved equipment and machinery. It deals with the manufacture and application of fire clay products, and does so in an interesting and realistic manner that can be appreciated readily by the specialist or the layman.

The film is three reels in length and requires about forty-five minutes to project. It is available in the 35 mm. and 16 mm. sizes for stationary or portable projectors. Copies are distributed by the United States Department of Commerce, Bureau of Mines, Pittsburgh, Pennsylvania, under the motion picture subject No. 97, "Story of Fire Clay Refractories," rental charge free.

The **Permold Company** has filed in the United States Federal Court at Cleveland, a suit against the Monarch Aluminum Ware Company for alleged infringement of Letters Patent of the United States No. 1,770,368, granted on the 8th day of July 1930. The Permold Company is asking an injunction and triple damages. It is understood that the suit has to do with metal molds such as are used for the casting of agitators, gyrators and dollies for washing machines.

Frank H. Adams, General Manager of the Surface Combustion Company of Toledo, Ohio, announces the acquisition of the Gas Equipment Division, including foundry of the Columbus Heating & Ventilating Company of Columbus, Ohio, manufacturers of gas fired warm air furnaces and unit heaters.

The Surface Combustion Company originally specialized in gas fired designed industrial equipment and have made great strides in the automotive, steel and other industries. Recently, this company also acquired the Chapman-Stein Company of Mt. Vernon, Ohio, in order to round out their services in the way of equipment to the steel industry. This was taken over about a year ago, and the Webster Engineering Company of Tulsa, Oklahoma, was taken over about two years ago.

The American Compilation Co. Offers

aids to your Research

through
elimination of routine work

YOU repeatedly struggle through the same routine work time after time. Work, which **if** filed after each step, would eventually lend unbelievable aid for future reference **if** you had completely exhausted any one field.

Surveys of two such exhausted fields are:

INDEX TO IRON AND STEEL PATENTS KINSEY HOPKINS

Second edition. Metallurgy complete, including all ferrous alloys. Price $25.00 per copy.

" . . . From 1844 to July 1st, 1930 . . . includes patentee, assignee, object of invention, method or analysis used, and the product."
Dr. H. W. Gillett, Director Battelle Memorial Institute.

" . . . . . it is more than an index. . . . . Since the searching of U. S. patents is an extremely tedious undertaking, this compilation will be of great value in the important field which it covers."
"Crucible" published by American Chemical Society, (Pittsburgh Section.)

The index is made up of six separate divisions including—patentees, assignees, types of irons and steels, suggested uses, constituents and classification. Supplements will follow. Sample page on request.

4000 NICKEL ALLOY PATENT ABSTRACTS
U. S. and FOREIGN

All ferrous and non-ferrous analyses, uses etc. for immediate reference. Price $10.00.

Estimates made on private literature surveys on request.

Technical manuscripts accepted for editing, publishing and distributing.

AMERICAN COMPILATION COMPANY
2nd FLOOR, LAW & FINANCE BLDG.
PITTSBURGH, PA.

PATENT DEPARTMENT

An arrangement with Mr. W. M. Corse, Metallurgical Engineer, Washington, D. C., who operates an Engineering Information Service, enables us to publish a list of important patents from the United States, Canada, England, Germany, France, Switzerland, Denmark, Holland, Sweden, Norway and Italy.
Copies of patents and translations will be supplied at reasonable cost. Patent searches made at minimum rates. Estimates cheerfully given.
Information about this service may be secured by writing to the Patent Department, **Metals & Alloys,** 810 Eighteenth Street, Washington, D. C.

United States Patents

Subject of Invention, Patentee, Patent No. and Filing Date.

Note: Numbers of Reissue Patents are preceded by "Re."

Process and mechanism for making metal pellets. D. Martin, 1,780,201, 8/13/28.

Process of producing a two-toned finish on metal surfaces. M. J. Udy, 1,780,-212, 7/28/27.

Method of preparing chromium-plated ferrous articles. V. M. Vertucci, 1,780,-213, 10/7/26.

Lead alloy amenable to hardening by heat treatment. (Pb–Sb–Cd). M. G. Corson, 1,780,261, 6/8/28.

Process of electric flash welding. W. F. Heineman, 1,780,297, 3/26/30.

Utilization of galvanizer's waste. W. G. Waring, 1,780,323, 7/6/29.

Die for flanging sheet metal. J. A. McGregor, 1,780,433, 3/7/28.

Core-molding mechanism. R. E. Dunham, 1,780,470, 1/28/29.

Operating blast furnaces. J. C. Hopkins, & A. Osolin, 1,780,485, 5/13/29.

Molding apparatus. A. T. Bateman, & A. Irvine, 1,780,514, 8/17/28.

Chromium plating. W. M. Phillips, 1,780,535, 6/30/26.

Acid treatment of metal articles. R. E. Lawrence, 1,780,594, 10/9/29.

Inhibitor. R. E. Lawrence, 1,780,595, 10/9/29.

Ingot-stripping mechanism. W. D. Keller & W. L. Poto, 1,780,787, 9/4/28.

Blowtorch support and scriber. R. B. Cregger, 1,780,814, 9/19/29.

Machine for testing and quantitatively indicating the cutting power and durability of blades and cutlery. K. Honda, 1,780,822, 9/18/26; Japan 1/20/26.

Device for treating rough tubes and analogous articles with lead. G. de Dudzeele, 1,780,870, 11/13/28; France 11/16/27.

Conductor. W. B. Ten Eyck, 1,780,953, 3/25/25.

Process for the securing of welds on bended bodies. A. Lützow, 1,780,978, 5/26/27; Germany 5/27/26.

Method of and mold for casting piston rings. E. N. Broderick & T. D. Lucier, 1,781,098, 12/20/26.

Method of cold rolling and coiling strips. H. M. Naugle & A. J. Townsend, 1,781,123, 4/28/27, original 9/23/24.

Method of making castings. J. H. Williams, 1,781,143, 3/7/27.

Mechanism for making molds. E. F. Oyster & F. N. Gilliland, 1,781,126, 8/2/28.

Anode of carbonized iron or the like. L. Smede, 1,781,305, 10/11/27.

Mold for casting ingots of steel or other metals. A. G. E. Hultgren, 1,781,293, 2/11/29; Sweden 2/22/28.

Conveying apparatus for dipping. M. J. Anderson, 1,781,425, 4/9/27.

Means for making double-sided molds. G. Eckstein, 1,781,451, 4/25/29; Germany 4/27/28.

Method of forming alloys. P. A. E. Armstrong, 1,781,490, 5/8/28.

Method of preparing metal for painting. J. H. Gravell, 1,781,507, 10/2/28.

Ferrous alloy. B. D. Saklatwalla, 1,781,527, 10/29/27.

Welding clamping device. L. H. Hoffer, 1,781,548, 9/26/29.

Apparatus for producing bent pipes of correct prescribed lengths. R. H. Böhling, 1,781,567, 4/6/29; Germany 6/14/28.

Process of producing malleable-iron castings. L. H. Marshall, 1,781,119, 4/27/28.

Universal ring-rolling machine. J. H. Taylor, 1,781,140, 12/10/23.

Die-casting machine. E. N. Dollin & C. C. Jacobson, 1,781,168, 2/23/28.

Chromium plating. J. F. K. McCullough & B. W. Gilchrist, 1,781,789, 9/30/27.

Electroplating machine. C. G. Miller, 1,781,791, 12/22/28.

Roll heater. J. D. Williams, 1,781,798, 10/24/28.

Rolling mill. W. F. Detwiler, 1,781,809, 12/14/27.

Electrode holder. P. L. Orr, 1,781,930, 2/12/29.

Multiple-mixture die-casting method and machine. A. Akers, 1,781,939, 8/11/27.

Slug-casting machine. J. A. McGinnis, 1,782,047, 5/27/27.

Articles having tarnish-resisting surface and process of making same. (Cr–Ag). D. Gray, *et al.*, 1,782,092, 5/16/23, renewed 12/13/26.

Testing device. J. L. Theobald, 1,782,127, 10/27/26, renewed 4/25/30.

Method of welding and the resultant product. O. U. Hofmann, 1,782,234, 12/31/28.

Pressure die-casting appliance. K. F. Wagner, 1,782,248, 2/17/28; Germany 2/19/27.

Aluminum alloy. H. C. Hall & T. F. Bradbury, 1,782,300, 10/23/29; England 12/18/28.

Method of welding. B. S. Robinoff, *et al.*, 1,782,316, 5/10/29.

British Patents

Subject of Invention, Patentee, Patent No. and Filing Date.

Note: When the date applied for differs from the date on which the application was lodged at the British Patent Office, the former date is given, followed by *.

Production of slags for use in the manufacture of wrought iron. A. M. Byers Co., 315,858, 7/21/28*.

Treatment of complex ores of copper, cobalt and nickel. R. S. Carreras, 336,584, 7/10/29.

Method of separating zinc, tin, lead, bismuth, cadmium, antimony, arsenic and similar elements from sulphide ores or secondary products by means of blast-smelting. E. J. Kohlmeyer, 336,670, 7/19/29.

Molding of liquid or plastic iron, steel and other metals and alloys difficult to mold. P. Multhaupt, 336,688, 7/26/29.

Hydraulic lead cutting-off devices for lead cable presses. F. Krupp Grusonwerk A.G., 336,695, 2/15/29*.

Casting of molten metals or alloys. H. Harris, 336,727, 8/27/29.

Frost protective or thawing agent for protecting metals against the effects of frost. G. Erdbrugger, 336,739, 9/9/29.

Presses for the production of metal cable sheathing and tubes. Felten & Guilleaume Carlswerk A.G., 336,742, 10/22/28*.

Methods of making tungsten and like metal carbides. British Thomson-Houston Co., Ltd., 319,698, 9/26/28*.

Recovering metal values from their ores or from metalliferous materials. Meyer Mineral Separation Co., 336,770, 9/30/29.

Rivets, and methods of manufacturing same. Vereinigte Leichtmetallwerke G. & C. Schwichtenberg, 336,803, 10/21/29.

Power straightening-machines for straightening shafts, bars, and the like. T. Oldfield, 336,843, 11/21/29.

Preserving aluminium from attack by alkalies. G. Adolph, 336,854, 11/29/29.

Method and apparatus for freeing and extracting castings from sand molds. L. A. Camerota, 336,857, 12/5/29.

Alloy, particularly for bearing-surfaces. H. C. Hall, 336,881, 12/30/29.

Annealing-furnaces. W. A. Morton, 336,596, 4/15/29*.

Testing magnetizable bodies. C. Kinsley, 336,987, 6/19/29.

Sheet-metal pipes and the like. A. R. Hutton, 337,020, 6/19/29.

Wire-heating furnaces. H. B. Blythe, 336,947, 6/22/29.

Manufacture of magnetic alloys. W. S. Smith, *et al.*, 336,948, 6/22/29.

Manufacture of iron or steel. H. Hagemann, 336,954, 7/18/29.

Working-up of chromium ores. I. G. Farbenindustrie A.G., 336,970, 7/22/29.

Method of manufacturing hydrocarbon-containing metals and alloys. Bayerische Metallwerke A.G., 316,103, 7/20/28*.

Pleated metal sheeting. M. Meltz, 337,038, 7/25/29.

Light metal alloy. H. T. Tillquist & J. Harden, 337,099, 8/17/29.

Cooling systems for centrifugal apparatus for casting metals. Ferric Engineering Co., 337,105, 8/22/29.

Treating sheet metal by rolling. Baldwins, Ltd. & D. J. Ledwith, 337,114, 8/28/29.

Manufacture of tungsten. A. Pacz, 337,160, 10/3/29.

Method and apparatus for manufacturing lead-headed nails. E. V. Swangren, 337,181, 10/18/29.

Application of varnishes, lacs or like coatings to metal surfaces. Herold A.G., 337,192, 4/30/29*.

Feed mechanisms for presses for operating on metal and other sheets. H. A. Griffiths, 337,230, 11/20/29.

Hot-blast stoves and the like. H. de Gaillard et Cie., 337,254, 2/16/29*.

Casting of metals. I. Sugimura, *et al.*, 337,286, 1/8/30.

Extrusion-presses for the production of rod-like or tubular-shaped bodies. F. Krupp Grusonwerk A.G., 337,300, 3/4/29*; 337,336, 5/31/29*.

Compressed-air plate-holder for double drawing on single-action presses. L. Schuler A.G., 337,312, 4/12/29*.

Manufacture of articles hardened by nitrogenization. F. Krupp A.G., 312, 349 5/25/28*; 337,404, 5/25/28*.

Furnaces or apparatus for the heat-treatment of metals and the like. A. Smallwood & J. Fallon, 337,362, 6/25/29.

Furnaces employing combustion heating and electric heating in combination. International General Electric Co., Inc., 316,229, 7/25/28*.

Chromium or chromium-nickel steel alloys. F. Krupp A.G., 337,349, 6/26/29*.

Production of age-proof welds by the fusion welding method. F. Krupp A.G. 316,555, 7/30/28*.

Method or process of casting stainless steel. W. E. Martin & J. A. Berlyn. 337,413, 7/29/29.

Coated metal bodies and process of producing same. American Rolling Mill Co., 337,399, 7/29/29.

Apparatus for the distillation of volatile metals. E. M. S. Industrial Processes, Ltd., *et al.*, 337,471, 8/3/29.

Mandrel-holders for vertical lead-coating presses for cables. F Krupp Grusonwerk A.G., 337,520, 10/25/28*.

Light metal alloy. Birmingham Aluminium Casting (1903) Co., Ltd., and P. Pritchard, 337,558, 10/9/29.

Protecting iron and steel. A.Folliet & N. Sainderichin, 337,562, 10/10/29.

Electrodes or rods for welding. J. H. Aitchison, *et al.*, 337,589, 10/25/29.

Manufacture of refractory materials from natural magnesium silicates. Metallges. A.G., 337,605, 11/9/28*.

Cementation processes for ferrous metals. A. Folliet & N. Sainderichin, 337,-635, 11/28/29.

Processes for treatment by volatilization of zinc ores and mixtures thereof. A. Folliet & N. Sainderichin, 337,636, 10/19/29.

Process for improving the mechanical properties, especially the compression yield point o farticles made from magnesium and its alloys. I. G Farbenindustrie A.G., 337,706, 3/11/29*.

Production of titanium steel. W. & H. Mathesius, 337,715, 3/16/29*.

Manufacture of stereotype printing plates. Wood Newspaper Machine, Corp., 337,728, 7/1/29.

Manufacture of iron and other metals. Davis Steel Process Corp., 315,760. 7/17/28*.

Production of iron chromium alloys which are stable on heating. Pilzen Skoda Works, 337,767, 4/18/29*.

Apparatus for degreasing materials. Imperial Chemical Industries, Ltd., & F. E. Rogers, 337,770, 8/1/29.

Treatment of lyes from chlorinated burnt pyrites. I. G. Farbenindustrie Akt.-Ges., 337,822, 8/8/29.

Manufacture of cast iron. Meehanite Metal Corp., 337,844, 8/13/29.

Metal extrusion presses. Hydraulik Ges. & O. Schlenstedt, 337,867, 8/24/26.

Alloys and articles made therefrom. R. A. Hadfield, 337,893, 9/11/29.
Steel alloy. Multi-Steel Co., 337,919, 1/24/29*.
Increasing the elongation and bending and rolling capability of sheets, bands, wires and the like consisting of aluminum alloys. Aluminium Industrie Akt.-Ges., 337,922, 10/12/28*.
Electrolytic production of aluminum. Vereinigte Aluminium-Werke Akt., Ges., 337,995, 11/27/28*.
Tilting-gear for crucible furnaces. J. H. Ludlow & Associated Electrical Industries, Ltd., 338,013, 11/25/29.
Welded butt-joints. J. Collinson & Associated Electrical Industries, Ltd. 338,030, 12/12/29.
Rotatable drums applicable for use in cooling materials discharged from rotary furnaces. F. Krupp Grusonwerk Akt.-Ges., 338,069, 1/18/29*.
Manufacture of iron alloys. Vereinigte Stahlwerke Akt.-Ges., 338,071, 1/30/29*.
Manufacture of aluminum by electrolysis. Cie. de Produits Chimiques et Electrometallurgiques Alais, Forges et Camargue, 338,084, 3/15/29.
Method of and apparatus for making sections by bending metal strips between pairs of rolls. J. Kozicz, 338,091, 3/20/29*.
Production of composite metal castings. W. Alberts & F. Stein, 338,092, 8/28/29*.

Canadian Patents

Subject of Invention, Patentee, Patent No. and Filing Date.

Manufacture of granulated products (from reduction of arsenic-bearing ores). H. C. Gardiner, 305,052, 4/28/30.
Metal painting method. J. H. Gravell, 305,056, 2/10/30; 305,576, 2/21/30.
Sheet metal stretching tool. H. Junkers, 305,068, 12/7/29.
Welded tubing. The Air Reduction Co., Inc., 305,116, 11/27/29.
Welded pipe. The Air Reduction Co., Inc., 305,117, 11/27/29.
Mold core. The Aluminium Ltd., 305,118, 7/31/29.
Molten slag processing (for wrought iron use). The A. M. Byers Co., 305,-138, 6/10/29.
Iron manufacture. The A. M. Byers Co., 305,139–305,142, 6/10/29.
Metal composition (Al–Cd–Cu). The Canadian General Electric Co., Ltd., 305,147, 12/7/28.
Mold treating method. The S. D. Warren Co., 305,237, 10/7/29.
Aluminum casting (Al–Cu–Ti). The Aluminum Co. of America, *et al.*, 305,261, 2/27/28.
Case-hardening metal. P. W. & E. B. Shimer, 305,281, 6/5/28.
Device for casting large accumulator plates. J. A. Fullilove, 305,331, 7/16/29.
Dental filling of high resistance to wear, well polishable and neutral to chemical agents (Cr–Ni with agglutinant). F. Hauptmeyer, 305,336, 12/4/29.
Apparatus for the reduction and recovery of volatilizable metals. W. Job, 305,341, 4/5/27.
Disengaging device on wire drawing benches. C. Rasch, 305,376, 12/4/29.
Production of malleable metal pipes. E. Weir, 305,388, 7/20/28.
Production of malleable metal pipes. E. Weir, 305,389, 5/15/29.
Metal sheet handling mechanism. The American Sheet & Tin Plate Co., 305,404, 1/10/30.
Manufacture of fused refractory metals. The Canadian Westinghouse Co., Ltd., 305,418, 4/4/25.
Method of treating composite wires. The Canadian Westinghouse Co., Ltd., 305,419, 2/9/26.
Method of sintering and fusing refractory metals. Same patentee, 305,425, 9/4/29.
Annealing furnace. The International Nickel Co., Inc., 305,470, 6/26/29; 305,471, 12/12/29.
Bearing metal (Pb–Sn–Na–Li–Al). The S. & T. Metal Co., 305,499, 5/31/29.
Structural steel. Vereinigte Stahlwerke Akt.-Ges., 305,526, 3/6/29.
Process of refining and mixing metals and alloys. G. E. Leavey & T. D. Kelly, 305,530, 2/15/29.
Protection of metals against corrosion (chromium plating). T. E. Murray, 305,533, 7/18/27.
Apparatus for forge welding cylinders, etc. J. Barrow, 305,556, 1/29/30.
Material for preventing metal from corroding. J. H. Gravell, 305,575, 2/21/30.
Metallurgical process for readily oxidizable metals. G. Michel, 305,594, 5/4/27.
Electro-deposition of zinc. U. C. Tainton, 305,614, 5/13/29.
Machine for making tapered tubes. The American Fork & Hoe Co., 305,639, 3/28/29.
Process of protectively treating aluminum and its alloys. The Arthur Arent Laboratories Inc., 305,643, 5/27/29.
Electrolytic recovery of zinc. Electrolytic Zinc Co. of Australasia, Ltd., 305,670, 4/19/27.
Apparatus for roasting or sintering ores. National Processing, Ltd., 305,717, 1/15/29.
Apparatus for reworking finely divided metal particles. The Schmeller Holding Co., 305,726, 1/28/28.
Crucible for manufacturing pipes. La Soc. d'Expansion Technique, 305,732, 4/6/29.
Forming die. The Woodings Forge & Tool Co., 305,743, 1/17/30.

French Patents

Subject of Invention, Patentee, Patent No. and Filing Date.

Sheet clamp for draw presses. L. Schuler Akt.-Ges., 694,213, 4/19/30.
Process for reducing metallic compounds. G. N. Kirsebom, 694,283, 4/22/30.
Discharge mechanism for ingot-heating furnaces. Ofenbau G. m. b. H., 694,653, 4/28/30.
Electrolytic process for the recovery of tin in compact form from alkaline liquors Siemens & Halske Akt.-Ges., Addition 37,495 (1st addition to 650,579 filed 3/8/28), 10/7/29.
Process for rendering steel insensitive to the action of hot gases and vapors. F. Krupp Akt.-Ges., Addition 37,502 (1st addition to 626,672 filed 12/23/26), 10/10/29.
Polishing machine, particularly for polishing thin sheets. Berg Heckmann Selve Akt.-Ges., 694,366, 4/24/30.
Molds for casting grooved cylinders. J. Neuville, 694,387, 4/24/30.
Improvements to the electrodes of welding machines. Edward G. Budd Mfg. Co., 694,409, 4/24/30.
Lead pipe. L. Prime, 694,423, 4/25/30.
Cementation pot or the like made of ordinary materials such as cast iron. F. Krupp Akt.-Ges., 694,665, 4/29/30.
Device for compressing the mold material in the production of foundry molds and cores. M. Grindal, Addition 37,501 (1st addition to 682,726 filed 10/3/29), 10/10/29.
Process for forging and swaging a bar of iron or steel. Soc. l'Ebauchage Electrique Procédés Giacchino, Addition 37,520 (1st addition to 682,314 filed 9/26/29), 10/21/29.
Instrument for directly reading the diameter of the impression in the Brinell test. R. G. Guillery, 694,502, 7/31/29.
Electrolysis of zinc. I. G. Farbenindustrie Akt.-Ges., 694,234, 4/19/30.
Assembling electric furnace electrodes. Siemens Planiawerke Akt.-Ges., 694,-428, 4/25/30.
Process for producing metallic sodium and potassium. J. Ylla-Conte, 694,587, 4/26/30.
Shear for cutting rolled material in motion. A. G. Schloemann, 694,799, 5/1/30.
Improvements to alloys of iron, nickel and copper and process for making these alloys. The International Nickel Co., Inc., 694,929 & 694,930, 4/12/30.
New process for heat treating steels and equipment for working it. A. P. Mahoux, 695,045, 8/8/29.
Press for working and shaping sheet metal. Marquette Tool & Mfg. Co., 694,698 & 694,699, 4/30/30.
Electro-pneumatic or electro-hydraulic upsetting machine. C. Strock, 694,898, 5/3/30.
Improvements to processes and machines for working metal, starting with a hollow blank. Bridgeport Brass Co., 694,926, 4/9/30.
Improvements to automatic welding apparatus. Svenska A. B. Gasaccumulator, 694,931, 4/14/30.
Improvements to resistance-heated electric soldering irons. J. M. V. Abeil, 694,968, 5/3/30.
Alloy for protecting iron, steel, copper, etc., against corrosion. Des Torpilles de Saint-Tropex, 695,050, 8/9/29.
Improvements to electric welding machines. J. E. J. Languepin, 695,066, 8/13/29.
Process for making structural iron members which are to be highly stressed. Vereinigte Stahlwerke Akt.-Ges., Addition 37,550 (2nd addition to 565,661 filed 4/30/23), 11/5/29.
Process for treating leucite or aluminous silicates to obtain pure alumina. G. Gallo, 694,885, 5/2/30.
Electrolytic process for producing certain metalloids, metals and alloys. J. L. Andrieux, Addition 37,559 (2nd addition to 638,345 filed 12/1/26), 6/17/29.
Process for making bearings of antifriction alloys. A. E. Ricard, 695,240, 5/6/30.
Rapid process for cementing and hardening fine wire or thin sheet metal. R. Riffaud, 695,398, 5/10/30.
Steel or cast iron having slight tendency to rust. Vereinigte Stahlwerke Akt.-Ges., 695,398, 5/10/30.
Improvements to ingot strippers. E. J. George & C. T. Howland, 695,484, 5/12/30.
Improvements to cupolas and similar furnaces. The British Cast Iron Research Assoc., *et al.*, 695,555, 5/14/30.
Improvements in the extraction and refining of metals. E. Vidal, *et al.*, 695,623, 5/15/30.
Process for forming colored protective layers on the surfaces of aluminum alloy objects. A. Pacz, 695,155, 8/14/29.
Process for joining metal pipes by welding. E. Didier, 695,339, 5/8/30.
Process for making corrugated sheets. H. Syrowy, 695,346, 5/9/30.
Machine for upsetting sheet metal. H. Junkers, Addition 37,613 (2nd addition to 603,544 filed 7/30/25), 11/13/29.
Method and instrument for measuring the hardness of materials. The Shore Instrument & Mfg. Co., 695,533, 5/13/30.
Means for mounting and controlling the electrodes of an electric furnace or electrolytic cell. A. Franchini & P. Girod, 695,216, 8/27/29.
Electroforming process. Metals Protection Corp., 695,360, 5/9/30.
Process for producing alumina. W. J. Muller & H. Hiller, 695,586, 5/14/30.
Improvements to plate shears. E. Fouquet & C. Nageotte, 695,735, 5/16/30.
Rolling process. J. J. G. Sart, 695,656, 9/4/29.
Process for producing aluminum and its alloys. T. R. Haglund, 695,697, 5/15/30.
Aluminum alloy. O. Kamps, 695,838, 5/19/30.
Method of working regenerative furnaces, especially furnaces for melting metals. W. Alberts & P. Zimmermann, 695,850, 5/19/30.
Steel compositions and process of making. Taylor-Wharton Iron & Steel Co., 695,871, 5/20/30.
Feed device, especially for sintering pots. P. Bernhardt, 695,899, 5/20/30.
Machine for making condenser tubes of zinc furnaces, or similar objects. S. A. Metallurgique de Prayon, 696,040, 5/23/30.
Improvements in the production of alloys. Cie Française pour l'Exploitation des Procédés Thomson-Houston, 696,142, 5/27/30.
Process for reducing granular materials containing stannic oxide. "Berzelius" Metallhütten G. m. b. H., 696,146, 5/27/30.
Process for producing volatilizable metals. Metallges. Akt.-Ges., 696,151, 5/27/30.
New arc welding process. Soc. Générale de Constructions Electriques & Mécaniques (Als-Thom), 695,638, 8/20/29.
Process for improving the quality of welds, particularly electric welds. Forges & Ateliers de Construction de Jeumont, 695,662, 9/4/29.
Improved electric welding process and welding rods used therein. A. O. Smith Corp., 695,704, 5/15/30.
Improved process for making coated welding rods for arc welding. A. O. Smith Corp., 695,705, 5/15/30.
Automatic device for moving welding and cutting torches. P. Tesson, 695,818, 5/19/30.
Process for cleaning metallic surfaces. J. H. Gravell, 695,914, 5/21/30.
Improvements to piston molds and method of casting. H. J. Hater, 695,920, 5/21/30.
Improved process for reducing tubing. S. A. d'Escaut & Meuse, 695,934, 5/21/30.
Stamping process. Aluminium Walzwerke Singen Dr. Lauber Neher Co. G. m. b. H., 696,069, 5/24/30.
Electric furnace. Soc des Grand Travaux Electriques, 695,761, 5/16/30.
Process for forming oxidized layers on aluminum and its alloys. R. E. Muller, 696,073, 5/24/30.
Improvements to composite substances, particularly mixtures and alloys. Energy Research Co., 696,206, 5/28/30.

Process for producing magnesium. A. C. Jessup, 696,218, 5/28/30.
Process and means for obtaining refined molten metals from their crude ores. Doherty Research Co., 696,418, 4/2/30.
Improvements to processes and apparatus for heat treating sheet metal. The Duraloy Co., 696,432, 4/18/30.
Process for treating materials containing copper and nickel. The International Nickel Co., Inc., 696,456, 5/8/30.
Process for treating ores containing sulphides. Sulphide Corp., 696,520, 5/22/30.
Rustless cast steel. B. Vervoort, 696,551, 5/28/30.
Furnace for sintering pulverulent ores and metallurgical products. Vereinigte Stahlwerke Akt.-Ges., 696,562, 6/2/30.
Special steel for railroad trackage material, such as rails, etc. P. P. Marthourey, Addition 37,657 (1st addition to 679,357 filed 12/11/28), 11/26/29.
Process for hardening structural steels containing copper. Vereinigte Stahlwerke Akt.-Ges., Addition 37,661 (1st addition to 671,416 filed 3/13/29), 11/26/29.
Centrifugal casting machine. M. Karminski, 696,202, 5/28/29.
Improvements to soldering and brazing torches. S. A. Le Carbone, 696,275, 9/13/29.
Means for backing the roll shafts of pilger mills. E. Rober, 696,409, 2/4/30.
Chain making machine. Mme. Helle, 696,445, 4/30/30.
Reproducing mechanism for torch welding or cutting machines. C. Krebs, 696,499, 5/19/30.
Improved welding machine. Ford Motor Co., Ltd., 696,525, 5/23/30.
Improvements in the electric welding of metal tubing. H. F. McLoughlin, 696,526, 5/24/30.
Fusible electrodes for welding aluminum and its alloys. La Soudure Electrique Autogène, 696,592, 6/3/30.
Tube bending machine. A. J. Galland, 696,628, 6/4/30.
Electric furnace electrode. Soc. Electro-Metallurgique de Saint-Beron, 696,319, 5/30/30.
Thermostat for electric resistance furnaces. S. A. de Commentry, Fourchambault et Decazeville, 696,529, 5/24/30.
Process for coating metal objects with tungsten or molybdenum bronzes. Egyesult Izzolampa Es Villamossagi Reszvenytarsasag, 696,588, 6/3/30.
Improvements to tunnel furnaces. Woodall Duckham (1930), Ltd., 696,563, 6/2/30.
Method and means of using the heat of waste gases from a rotary furnace. Fellner & Ziegler Akt.-Ges., 696,602, 6/3/30.

German Patents

Subject of Invention, Patentee, Patent No. and Filing Date.

Rolling-mill cooling device with cooling elements at the rolls. Maschinenfabrik-Akt.-Ges. vorm Ehrhardt & Sehmer, 512,636, 8/16/29.
Roller bed with individual electric drive for the rollers. Fried. Krupp Grusonwerk Akt.-Ges., 512,123, 5/30/29.
Multiple wire-drawing machine. W. Nacken, 512,216 (Addition to 511,090), 4/14/28.
Method of rolling. Vereinigte Stahlwerke Akt.-Ges., 512,217, 7/19/29.
Draw-press. The Hamilton Press & Machinery, 512,124, 12/9/28.
Safety-lock for clutch bars, particularly for sheet metal working machines. M. Lang, 512,557, 8/9/29.
Device for feeding material to eccentric presses. H. Spörl, 512,126, 9/3/29.
Process for making profiled rings (tire rims). Budd Wheel Co., 512,558, 3/16/28; U. S. 3/15/27.
Machine for rolling pre-formed steel balls. J. Maier, 512,127, 2/23/28.
Process for decomposing aluminiferous materials, particularly bauxite, with reducing agents and pyrites. Vereinigte Aluminium-Werke Akt.-Ges., 512,564, 12/25/29.
Device for blowing gas into the tuyères of blast furnaces. Fried. Krupp Akt.-Ges., Friedrich-Alfred-Hütte, 512,574, 1/20/29.
Process for making high-test gray cast iron. Vereinigte Stahlwerke Akt.-Ges. and K. Emmel, 512,391, 12/10/24.
Mandrel to be inserted in molten metal in a crucible for the purpose of preventing formation of stresses on reheating. T. Metzger, 512,338, 12/9/28.
Method of working a conveying and discharge device for industrial furnaces. Benno Schilde Maschinenbau-Akt.-Ges., 512,491, 5/11/28; U. S. 12/8/27.
Process for making electric heating resistances by molding and firing a mixture of coal and metallic oxides. Electroterm Akt.-Ges., 512,264 (Addition to 481,796), 1/23/30.
Process for replenishing self-baking electric furnace electrodes. Siemens-Planiawerke Akt.-Ges. für Kohlefabrikate, 512,499, 1/22/27.
Device for arc welding, using a protective medium which is not gaseous at ordinary temperature. Siemens-Schuckertwerke Akt.-Ges., 512,500, 8/18/27.
Method and machine for charging sand into molds. H. Weber & K. Grocholl 512,269, 10/6/28.
Process for filling holes in metallic objects, particularly castings. Metallisator Berlin Akt.-Ges., 512,347, 2/21/30.
Machine for ejecting pipes from molds. S. A. des Hauts Fourneaux et Fonderies de Pont-à-Mousson, 512,348, 9/12/29, France 4/27/28.
Process for sintering dusty ores and metallurgical products in a shaft furnace, Vereinigte Stahlwerke Akt.-Ges., 512,171, 11/10/29.
Electrode plate for leading the current into anode material in lump form. Imperial Chemical Industries, Ltd., 512,277, 1/20/29; Great Britain 2/25/28.
Anode arrangement for the electrolytic refining of noble metals. Siemens & Halske Akt.-Ges., 512,172, 5/15/28.
Method of transferring heated material from a closed heating container into a cooling container which is movable relative to it. Akt.-Ges. Brown, Boveri & Cie., 512,173, 12/2/25.
Mill for rolling sections. F. Möller, 513,122, 1/3/30.
Machine for attaching fins to wrought iron tubing. Z. Rodakowski, 512,713, 8/2/29.
Damper for gas-fired furnaces, particularly blast heaters. Zimmermann & Jansen G. m. b. H., 513,109, 11/29/28.
Process for the direct production of metals, particularly iron. Allgemeine Elektricitäts Ges., 513,110, 9/22/26.
Ferrous alloy containing chromium and aluminum and process for heat treating the same to develop high permeability. W. H. Smith, *et al.*, 512,727, 4/29/28; Great Britain 4/20/27.
Process for annealing sheets in a vertical position in annealing boxes. R. Eickworth, 512,888, 12/22/26.
Ironless high-frequency furnace. Heraeus-Vacuumschmelze Akt.-Ges. 512,819, 8/9/27.
Process for soldering butt joints in copper cables. C. Cremer, 512,701, 11/26/26.
Machine for electrically welding thick-walled tubing. A. Pretzschner G. m. b. H., 513,135, 1/1/29.
Machine for welding tie plates to iron ties. Siemens-Schuckertwerke Akt.-Ges., 512,653 (addition to 507,150), 12/16/26.
Method of connecting arc-welding transformers. E. Schröder, 512,978, 6/2/28.
Jolt molding machine. Tabor Mfg. Co., 513,140 (Addition to 510,493), 5/4/29; U. S. 7/2/29.
Roller drive for centrifugal casting machines. W. H., Beatty, *et al.*, 513,141, 12/8/28.
Process for casting reinforced bearings. Eisen- & Stahlwerk Walter Peyinghaus, 513,053, 2/19/27.
Production of low-silicon, carbon-free metals and alloys, particularly manganese. J. Debuigne, 513,112, 9/1/23.
Recovery of copper from the lixivia of chloridizing-roasted pyrites. Reymersholm Gamla Industri A.B., 513,149, 10/3/26; Sweden 9/20/26.
Detinning tin-coated metal. P. Marth, 512,749, 10/18/28.
Chemically-resistant objects made of silver alloys. I. G Farbenindustrie Akt.-Ges., 512,986, 6/20/26.
Utilization of aluminum alloys containing magnesium and titanium. R. Müller, 513,016, 9/19/26.
Non-conducting border for cathodes used in electrodeposition of metals. Metallges. Akt.-Ges., 512,913, 11/8/27.
Increasing the electrical conductivity of commercial aluminum. Siemens & Halske Akt.-Ges., 513,017, 8/22/26.
Torsion machine, particularly for testing. A. J. Amsler, 512,915, 4/17/29.
Charge-supporting bars for muffle furnaces. Metall-Industrie J. Klefisch, 512,992, 4/23/29.
Muffle-furnace bottom. Same patentee, 512,993, 4/27/29.
Rolling mill. R. Kronenberg, 513,283 (Addition to 449,011), 6/21/29.
Pinion housing for three-high mills with frictionally-driven middle roll. F. Grah, 513,523, 2/27/30.
Mechanism for turning rolled material. J. P. Kieffer, 513,524, 1/3/30.
Arrangement of the dies of multiple wire-drawing machines. W. Nacken, 513,459, 9/14/29.
Tool for attaching helical ribs to a pipe. J. O. Huse, *et al.*, 513,460, 7/29/27; U. S. 8/6/26.
Process for producing pure iron. I. G. Farbenindustrie Akt.-Ges., 513,362, (Addition to 493,778), 1/14/28.
Modification of the apparatus for hardening the heads of rails to permit simultaneous hardening of several rails. Eisenwerk-Ges. Maximilianshütte, 513,212 (Addition to 503,369), 1/8/28.
Method of preventing penetration of carbon into parts of metallic objects during Case hardening. Vereinigte Schweiss- & Apparatebau-Werke G. m. b. H., 513,465, 7/25/29.
Process for making self-baking electrodes. Det Norske A/S for Elektrokemisk Industri, 513,226, 3/16/26; Norway 4/7/26.
Sand-projecting molding machine. W. Seidemann, 513,378, 8/31/29.
Sand-preparing machine. Badische Maschinenfabrik & Eisengiesserei 513,516, 10/25/28.
Mechanical purification of metals and non-metallic ingredients. Braunschweiger Hüttenwerk G. m. b. H., 513,273, 7/3/26.
Cell for electrolytic separation of metals. I. G. Farbenindustrie Akt.-Ges. 513,188, 2/22/27.
Process for cleaning metallic surfaces, particularly for the removal of oxide layers. J. Janz, 513,454, 5/25/28.
Soldered joint. Victoria-Werke Akt.-Ges., 513,406, 11/2/28.

Norwegian Patents

Subject of Invention, Patentee, Patent No. and Filing Date.

Process for making sections with uniform wall thickness by die-pressing. I. G. Farbenindustrie Akt.-Ges., 48,566, 8/22/29.
Chill mold. J. Züblin, 48,577, 9/21/27.
Centrifugal process and machine for making or lining pipes and the like. Hume Steel, Ltd. 48,591, 2/2/29.
Process for roasting pyrites. M. Abel, 48,606, 5/8/29.

Swedish Patents

Subject of Invention, Patentee, Patent No. and Filing Date.

Method of operating electric annealing furnaces. Akt.-Ges. Brown, Boveri & Cie., 70,696, 6/22/27, Priority 6/23/26.
Process for making carbon electrodes which are protected against burning in air, I. G. Farbenindustrie Akt.-Ges., 70,844, 11/27/28, priority 12/23/27.

Swiss Patents

Subject of Invention, Patentee, Patent No. and Filing Date.

Process for making a rust-preventive and acid-proof paint for metals and the like. W. Seeger, 141,887, 8/22/28; Germany 8/22/27.
Process for coating iron or steel objects. Soc. Continentale Parker, 141,898, 12/17/28.
Process and machine for making electrically-welded tubing. F. Sönnichsen *et al.*, 141,938, 7/4/29; Norway 8/11/28.
Hot-rollable bimetals and process for making the same. Metallges. Akt.-Ges. 141,943, 7/31/29.
Furnace for annealing metals under a protective hood. Siemens-Schuckertwerke Akt.-Ges., 141,944, 7/15/29; Germany 5/1/29.
Electric annealing furnace. Akt.-Ges. Brown, Boveri & Cie., 142,004, 9/17/24; Germany 9/24/28.
Electrically-conducting coating and process for making the same. Einstein's Electrochemical Process, Ltd., 142,176, 2/28/29.
Process for making copper-bearing cast iron or steel. F. Heusler, 142,213, 8/8/29; Germany 8/20/28.
Aluminum alloy. Metallges. Akt.-Ges., 142,214, 11/6/29; Germany 12/7/28.
Process and apparatus for melting easily fusible metals. C. Brackelsberg, 142,215, 11/1/29; Germany 8/20/29.
Process for making a flux for aluminum. W. Reuss, 142,216, 6/4/28; Germany 2/15/28.
Electric brazing and welding torch. G. Ruthardt, 142,217, 9/20/29.
Process for coating metals with aluminum or aluminum alloys. Vereinigte Silberhammerwerke Hetzel & Co., 142,221, 9/20/29; Germany 10/3/28.
Continuous furnace for annealing strip wire and the like. Siemens-Schuckertwerke Akt.-Ges., 142,222, 10/21/29; Germany 1/30/29.

MANUFACTURERS' LITERATURE REVIEWS

In this department we each month list the catalogs and other printed matter issued by manufacturers. Unless otherwise noted, any of the items listed may be secured free upon application to the issuing firm. Manufacturers who have not yet sent in their printed matter are invited to do so.

1 **"Shear Cut" Hobs.**—The engineers of the Illinois Tool Works have designed a hob with a shearing action which gives the same production advantages that a spiral gash or shear gives a milling cutter. Due to this shearing action it has been termed the "Shear Cut" Hob. General reconstruction as to the sizes of hobs, etc., are set forth in a leaflet published by the Illinois Tool Works, 2501 N. Keeler Ave., Chicago, Ill.

2 **Steel.**—The P. F. McDonald & Co., 17 King Terminal, Boston, Mass., have recently issued a leaflet which lists the various steels manufactured by them. Special attention is paid to their die, chisel and tool steels. Suggestions for heat treatment of these are given.

3 **Die Steel.**—Vanadium-Carbon-Die-Steel, VanDieCar, is fully described in a new folder sent out by the Ziv Steel & Wire Co., 2945 W. Harrison St., Chicago, Ill. The method for hardening and drawing this steel is given.

4 **Facts for Foundrymen.**—This convenient 48-page booklet is intended as a foundryman's handbook giving a useful description of various metals and alloys that may assist in the production of more perfect castings. Niagara Falls Smelting & Refining Corp., 2204 Elmwood Ave., Buffalo, N. Y.

5 **Drilling Manganese Steel.**—The Hercules Major Drill has proven itself pre-eminent in the field of manganese steel drilling. A leaflet published by Whitman & Barnes, Inc., Detroit, Mich., tells how to drill high manganese steel using Hercules Major drills. A list giving specifications for these drills is included. Another leaflet issued by the same company describes their Blue Diamond High Speed Drills.

6 **Speed Regulator.**—Catalog No. D-88 gives detailed information about the Reeves transmission and describes its applications in scores of industries. It will be convenient for reference on any problems involving accurate regulation. Reeves-Bond Sales Co., 39 S. Clinton St., Chicago, Ill.

7 **Alloy Steels in the Railroad Field.**—An interesting article with the above title written by Charles McKnight was presented before the A.S.M.E. and is reprinted by the International Nickel Co., Inc., 67 Wall St. New York, N. Y.

8 **Airplane Pulleys.**—Micarta control-wire pulleys for airplanes are discussed and described in a new publication, identified as D.M.F. 5300-A. issued by the Westinghouse Electric and Manufacturing Company, East Pittsburgh, Pa. This publication contains tabulations showing the style numbers, dimensions and list prices of the pulleys, and includes photographs and drawings of them.

9 **Reducing Furnaces.**—Ability of Strong, Carlisle & Hammond Engineers to meet the requirements of any industrial furnace user is well demonstrated in a new installation of two SC & H gas-fired furnaces used in the reduction of certain metals. These are described in a leaflet issued by the Strong, Carlisle & Hammond Co., Cleveland, Ohio.

10 **Condensate Pumps.**—Westinghouse single-stage condensate pumps have been developed to meet the demand for efficient reliable units with low installation and operating costs. Each pump is so designed that ready access may be had to all interior parts, and all parts that are subject to wear are easily renewed. These are fully described and illustrated in a folder sent out by the Westinghouse Electric Mfg. Co., Philadelphia Works, Philadelphia.

11 **Carburizing Containers.**—For the past 10 years the Driver-Harris Co. have been experimenting with "Nichrome" Sheet, in the form of carburizing containers and they are now in an advantageous position to meet the recent increased demand for sheet containers. They have compiled a brochure showing "Nichrome" sheet, cast "Nichrome" and other "Nichrome" installations. Driver-Harris Co., Harrison, N. J.

12 **Manganese Steel Equipment.**—A great variety of equipment parts manufactured by the American Manganese Steel Co., Chicago Heights, Ill. are illustrated in a folder recently sent out by the company. These are more fully described in the Amsco Catalog, which can be obtained from the company. In the October 1st issue of the Amsco bulletin there are interesting illustrations of oil well equipment in which Amsco sheaves are used.

13 **Acid Proof Pipe.**—A bulletin distributed by the American Manganese Steel Co., St. Louis, contains test reports of its acid-resisting pipe. This material can be economically used in various ways.

14 **Nonferrous Ingot Metals.**—A booklet sent out by the Tottenville Copper Co., Inc., New York, gives a list of the various standard formula ingots this company produces. Their chemical and physical properties, and applications are also given.

15 **Steel Castings.**—Transportation units acquire a high degree of safety from steel castings manufactured by the Lebanon Steel Foundry, Lebanon, Pa. according to a bulletin recently issued by the company.

16 **Protective Coatings.**—Two bulletins sent out recently by the Headley Emulsified Products Co., Philadelphia, describe its waterproofing compounds and its asphalt-base aluminum coating.

17 **Sheet Steels.**—The special sheet steels manufactured by the Superior Sheet Steel Co., Canton, Ohio, are put to varied uses. These are illustrated in a recent bulletin issued by the company.

18 **Electric Steel.**—Steels produced in an induction furnace are discussed in detail in a bulletin of the Heppenstall Co. of Pittsburgh, Pa.

19 **Steel Castings.**—Great care is used in the foundry of the Industrial Steel Casting Co. of Toledo, Ohio, to produce castings of high grade. The advantage of steel castings is discussed in their current bulletin.

20 **Steel Deoxidizer.**—The Vanadium Corp. of America, New York, manufactures a steel deoxidizer containing aluminum, silicon and iron. Its advantages and uses are described in a recent bulletin sent out by the company.

21 **Wire Tables.**—Useful tables showing the breaking strength of various types of copperwelded wire have been published by the Copperweld Steel Co., Glassport, Pa.

22 **Arc Welding.**—This booklet sent out by the Lincoln Electric Co., Cleveland, Ohio, gives much detailed information on the advantages of arc welding. It gives the results of tests conducted in the laboratory of the company.

23 **Heat Treatment.**—This attractive 75-page booklet discusses the heat treatment of steel, and after telling how electric heat treatment affects production costs it describes a number of standard electric furnaces manufactured by the General Electric Co., Schenectady, New York. Another small pamphlet (GEC 93) issued by the same company describes their welding electrodes. Several new leaflets describing the G. E. Conveyor Furnace, G. E. Air-Draw Furnace and Direct-Heat Electric Furnace have been sent out by this company. These last are for filing in the G. E. binder.

24 **Forging.**—A paper "Nickel-Alloy Steel Forging" by Charles McKnight, which was presented before the A.S.S.T., has been reprinted in the new leaflet published by the International Nickel Company, 67 Wall St., New York. This is punched for filing in their binder "Nickel Steel." This company has also collected a number of leaflets which they put together under the title: "Nickel Cast Iron." These are mostly reprints of articles pertaining to this subject which have appeared recently, with the addition of some original articles by members of the company. An interesting booklet gotten out by the same company is entitled: "The Use of Nickel in Non-Ferrous Castings." The data for this has been collected by the research department of the company.

25 **Alloy Steel.**—"Miraculoy," a new alloy having unusual tensile strength and hardness is discussed in a folder issued by the Sivyer Steel Casting Company, 37th Ave., and Mitchell St., Milwaukee, Wis.

26 **Pyrometers.**—Electrical pyrometers and thermometers for measuring all temperatures between −2500 and + 3000° C. or −4200 and +5500° F. are described in Bulletin 10 published by the Thwing Instrument Company, 3339-41 Lancaster Avenue, Philadelphia, Pa. The 3 general types, thermocouple pyrometers, radiation pyrometers and resistance thermometer. are taken up.

27 **Temperature Control.**—Catalog L 3 published by the Wilson Maeulen Company, 383 Concord Avenue, New York, discusses in detail pyrometers of recording, indicating and automatic control types. The catalog is fully illustrated.

28 **Metal Cleaning.**—Antoxylin is a new chemical fluid for use in preparing metals prior to the application of all kinds of primers, paints, lacquers, etc. This preparation removes the impurities from the surface of the steel and then forms a film which excludes all air, moisture, etc., leaving the surface ready for finishing. Bulletin No. A, issued by the Antoxylin Chemical Corporation, 42 Broadway, New York City.

29 **99.99 + % Zinc.**—This very interesting booklet issued by the St. Joseph Lead Company, 250 Park Avenue, New York, contains much detailed information about "Bunker Hill" 99.99+% zinc, for use in die-castings. Mr. Sam Tour, metallurgist, well known in the die-casting industry, has made experiments and reports which are included in this pamphlet.

30 **The Scovill Standard.**—The October issue of this magazine published by the Scovill Manufacturing Company, Waterbury, Connecticut, contains an interesting article on Air Transportation, in addition to an article on Light, Heat and Power, a discussion of public utilities.

31 **"Kromepatch."**—A 4-page folder compares this chrome ore base cement with other cements for use in furnace linings. This is distributed by the E. J. Lavino Company, Bullitt Building, Philadelphia.

32 **Set Screws.**—The Bristol Company, Waterbury, furnish set screws with 6 different styles of points, designed to perform various classes of setting work. These different styles are illustrated and the prices of the different sizes tabulated in a leaflet issued by this company.

33 **Carburizing Compound.**—The J. W. Kelly Co. of Cleveland, Ohio has recently taken over the distribution of the Beacon Brand products. Their carburizing compound, cleaners and oils for several uses are described in a booklet entitled: "Beacon Brand and the Industry," published by the J. W. Kelley Co.

34 **Rust Prevention.**—Several leaflets published by the Dearborn Chemical Company, 310 S. Michigan Avenue, Chicago, Ill., describe the use of No-OX-ID, in various ways. Another leaflet by the same company describes the use of Dearborn Cleaner in powder form.

35 **Control Pyrometer.**—Republic Control Pyrometer eliminates all metallic contacts, replacing them with a gas-filled mercury-switch. Republic Flow Meters Co., 2240 Diversey Parkway, Chicago, Ill.

36 **Shakeproof Lock Washer.**—4-page broadside which describes and illustrates a lock washer manufactured by the Shakeproof Lock Washer Company, 2501 North Keeler Avenue, Chicago, Ill.

37 **Steel Stamina.**—The summer issue of this publication contains an article on nitriding, and data comparing the 4 commercial methods of obtaining hardness values. Lindberg Steel Treating Co., 222-226 Union Park Court, Chicago, Ill.

CURRENT METALLURGICAL LITERATURE ABSTRACTS

These abstracts are not critical, but merely review developments. The classification number at the end of each abstract will be of assistance in mounting them on filing cards.

GENERAL (0)

Trends in Cast Alloy Steels. Staff article—interview with A. W. LORENZ (Bucyrus-Erie Co.), & DAVID C. ZUEGE, (Sivyer Steel Casting Co.) *Product Engineering*, Vol. 1, Dec. 1930, pages 560–561.

Total output of alloy steel castings is analyzed. Properties imparted by Mn, Cr, Ni, Mo, V, singly and in principal modern combinations, are summarized. MFB(0)

Principles of the Shaping and Annealing of Metals. (Stoffliche Grundlagen der spanlosen Verformung und Glühbehandlung von Metallen.) G. SACHS. *Metallwirtschaft*, Vol. 9, March 14, 1930, pages 238–242.

6 references. A review of cold and hot working, power, requirements, drawing, extruding, effect of residual strains due to working, heat treatment and recrystallization. CEM(0)

Evaluation of Raw Materials for the Iron and Steel Industry. ALFONS WAGNER. *Foundry Trade Journal*, Vol. 43, July 10, 1930, page 27.

Abstract translation of article in *Stahl und Eisen*. See *Metals & Alloys*, Vol. 1, Aug. 1930, page 688. VSP(0)

Apprenticeship, the Need of the Metal Trades. HAROLD S. FALK (Falk Corporation). *Machinery*, Vol. 36, June 1930, pages 771–774.

Discusses the lack of apprentice training in the industries and the possibility of development of such training. The writer believes that apprentice training is essential to the building of a strong personnel in the metal trades and to the growth and development of the industry. RHP(0)

Nickel Alloy Steel Forgings. CHARLES MCKNIGHT (International Nickel). *Transactions American Society for Steel Treating*, Vol. 18, Aug. 1930, pages 129–146.

Paper presented before the Semi-Annual meeting in New York February 7 and 8, 1930. Includes discussion. The author brings together the results of the experience of several manufacturers of large forgings of nickel and nickel alloy steels discussing their manufacture, effect of alloys, analyses used, heat treatment, properties and inspection. The discussion includes the machinability of such forgings. WLC(0)

PROPERTIES OF METALS (1)

Lithium—The Lightest Metal. H. S. SPENCE. *Canadian Mining Journal*, Vol. 51, Oct. 24, 1930, page 994.

An outline of the present stiuation regarding lithium ores in Canada. The Silver Leaf Mining Co. has opened a property about 10 miles northeast of Pointe-du-bois, where the principal minerals found are: lepidolite, spodumene, and montebrasie (a variety of amblygonite). WHB(1)

Beryllium as a Possible Structural Metal. C. B. SAWYER. *Journal Society Automotive Engineers*, Vol. 26, Jan. 1930, page 98.

Beryllium has the following peculiar combination of properties which justify the most serious engineering attention: very low density; high strength comparable to that of steel. Its one serious fault as a structural metal is that it lacks ductility. The composition of beryl is such that it resembles clay with part of its aluminum oxide replaced by beryllium oxide. (1)

The Magnetic Characteristics of Nickel. F. TYLER. *London, Edinburgh & Dublin Philosophical Magazine & Journal of Science*, Vol. 9, May 1930, pages 1026–1038.

Quantum and classical theory curves for the variation of the spontaneous magnetization with temperature below the Curie point are obtained and compared with the experimental results for nickel. Curves corresponding to large external fields are also considered. There seem to be irregularities in the variation in magnetization close to the Curie point. Discusses magnetic data for temperatures above the Curie point. Presents a possible explanation of the magnetic characteristics. There are several objections to this explanation, however, no definite conclusions can be drawn until the relation between conduction electrons and interaction electrons is more fully worked out. RHP(1)

A Note on Metallic Magnesium. W. R. D. JONES. *Journal of the Institute of Metals*, Vol. 43 (1930) pages 237–240.

See *Metals & Alloys*, Vol. 1, Aug. 1930, page 688. (1)

Experiments on the Apparent Deviation from Ohm's Law for Metals at High Current Densities. H. MONTEAGLE BARLOW. *London, Edinburgh & Dublin Philosophical Magazine & Journal of Science*, Vol. 9, May 1930, pages 1041–1055.

Several investigations have been made in this field all of which, except one by Bridgman indicate that very slight, if any deviations exist. Bridgman claims to have observed and measured a definite increase in the effective resistance of gold and silver films to currents of the order 10^6 amp/cm^2. Gives briefly Bridgman's methods and results. The author uses the same methods but with certain refinements to obtain a higher degree of accuracy. His methods are outlined and results given. The conclusions drawn seem to indicate that Bridgman secured some erroneous results and that Ohm's law holds for relatively high current densities. RHP(1)

The Fatigue of Metals—A Review of Progress from 1929 to 1930. H. F. MOORE. *American Metal Market*, Vol. 36, Nov. 6, 1930, pages 11-12.

See *Metals & Alloys*, Vol. 1, Jan. 1930, page 336. WHB(1)

The Properties of Pure Nickel. LOUIS JORDAN & WILLIAM H. SWANGER. *Bureau of Standards Journal of Research*, Vol. 5, Dec. 1930, pages 1291–1307.

Rather pure electrolytic nickel was further purified by annealing in hydrogen. A study was made of suitable refractory crucibles and of melting conditions to produce extremely pure compact metal. The ingots finally prepared were of a purity of 99.94%. New determinations of many of the physical properties of nickel have been made on the very pure metal thus made available. Data are given on density, crystal-lattice constant, melting point, electrical resistivity, magnetic properties, thermal e. m. f., thermal expansion, hardness, tensile strength and reflectivity. (1)

The Purification of Manganese by Distillation. JAMES B. FRIAUF (Carnegie Institute of Technology). *Transactions American Society for Steel Treating*, Vol. 18, Aug. 1930, pages 213–219.

Includes 9 references. Describes the induction furnace set up for the purification of metallic manganese under vacuum. Analysis showed carbon 0.004%, and silicon 0.002% with the spectroscope showing no iron and only traces of aluminum. WLC(1)

Aluminum, the Light Metals and Their Alloys. (Aluminium, Die Leichtmetalle und ihre Legierungen.) PAUL MELCHIOR. (AEG-Berlin). *Zeitschrift Verein deutscher Ingenieure*, Vol. 74, Sept. 13, 1930, pages 1267–1272.

The properties of the technical "light-metals," i. e., aluminum, magnesium and their alloys with other metals have been collected and tabulated in the "Aluminum Book" of the author. The most important properties for the designer are given, electric and thermal constants of the light rolling metals and cast alloys, tensile strength as function of the chemical composition and pre-treatment, admissible stresses and constructive utilization of the low specific gravity. Most of these properties depend on the purity of the metal and kind of alloy. Rolling metals are: (1) Pure aluminum; (2) Refined Al-alloys of high tensile strength; (3) Refined Al-alloys of high electric conductivity; (4) Aluminum alloys of especially high resistance against corrosion; (5) Electric. Cast alloys are: (*a*) aluminum alloys with additions mainly of Cu, Zn, Si; (*b*) refinable Al-cast alloys; (*c*) electron. Numerical figures of most of the before-mentioned properties are given and tabulated, and fields of applications named. All light-metals, even if containing iron in comparatively high amounts, are non-magnetizable. Ha(1)

The Influencing of Intensities in the Mercury Spectrum. (Zur Beeinflussung der Intensitäten in Quecksilberspektrum.) ERNST LUEBCKE. *Wissenschaftliche Veröffentlichungen aus dem Siemenskonzern*, Vol. 9, No. 2 (1930) pages 246–251.

If in a vacuum mercury arc the cathode space is cooled a change in color of the emitted light can be observed due to a strengthening of the initial single terms and a weakening of the initial triplette terms. The distribution of potential and temperature of room and electrons measured at the same time permits the conclusion that this optical phenomenon is caused by the increased velocity of the not-ordered electrons. Ha(1)

The Freezing Point of Nickel as a Fixed Point on the International Temperature Scale. H. T. WENSEL & WILLIAM F. ROESER. *Bureau of Standards Journal of Research*, Vol. 5, Dec. 1930, pages 1309–1318.

The freezing point of nickel was determined by measuring with an optical pyrometer the ratio of brightness of red light of wave length 0.6533 μ emitted by black bodies at the freezing points of nickel and gold, respectively. The nickel was frozen in magnesia crucibles *in vacuo*. The freezing point was found to be 1455° C. on the International Temperature Scale with an uncertainty of 1°, based on the value 1063° C. for the freezing point of gold and 1,432 cm. deg. for C_2. The temperature coefficient of resistance of the two separate ingots of nickel used was approximately 0.0067 in the interval 0° to 100° C. The chemical analyses indicated the purity of the nickel as 99.94%. The importance of the nickel point in optical pyrometry is discussed. The freezing point of pure nickel in magnesia crucibles was found to be very satisfactory as a fixed point in accurately extending the high-temperature scale beyond the platinum point. (1)

PROPERTIES OF NON-FERROUS ALLOYS (2)

Elastic and Tensile Characteristics of Some Light Alloys. (Caratteristiche di elasticità e resistenza di alcune leghe leggere.) G. COLONNETTI & G. M. PUGNO (Royal School of Engineering, Turin.) *La Metallurgia Italiana*, Vol. 22, Nov. 1930, pages 963–975.

The modulus of elasticity was determined on a 150 mm. (6″) test length for Lautal with an Ewing extensometer, and on the other alloys on a 50 mm. (2″) test length with a Martens extensometer reading to 0.0001 mm. The detailed figures for every reading are given, as well as plotted in curves. The stress-strain diagrams for Lautal were only slightly curved, but those for Avional and Anticorodal were noticeably curved. There is, therefore, a marked difference between the average moduli determined over the full range and over a small range of loading. In all tests there was a considerable hysteresis loop between the loading and unloading curves. Conclusions are are drawn as to the force of restitution compared to that of deformation. It is thought by the authors that the thermo-dynamic causes for the phenomena should be sought by profound further study. Since the illustrations show that the bars were held in ordinary wedge grips and apparently no duplicate bars were tested, it is a question whether the data are really as precise as the authors believe. Their summarized data follow:

No.	Name	Composition Al	Cu	Si	Mn	Mg	Condition	Tensile Properties Elas. Lmt. lbs./in.²	Ten. Str. lbs./in.²	Avg. Mod. Elas. lb./in.²	Elong. %	Red. Area %	90° bends over 7.5 mm. (0.3″) radius

New Products

Automatic Excess Temperature Cutout

The automatic excess temperature cutout of the Hevi Duty Electric Company can be applied to any type of furnace to guard the work or furnace from damage due to overheating.

It has been the practice to employ an excess temperature fuse or link in the furnace control system which was intended to melt in case the furnace exceeded safe temperatures. The shortcomings of this method brought about the development of the automatic excess temperature cutout.

The instrument responds to a thermocouple located in the furnace chamber which actuates a thermal cutout to control a relay which is a part of the furnace control system. Adjustable controls are provided so that the instrument can be set for any desired temperature. It can be calibrated for any thermocouple and used for protection purposes up to 3000° F. In case the furnace temperature rises to the set point, contact is made and the heating source interrupted. Warning is provided also, against failure of the thermocouple operating this instrument.

When the relay is actuated, the heating source is shut off, and a light indicates or an alarm bell may be rung to attract the attention of the operator.

◆ ◆ ◆

Wazau Brinell Hardness Tester

In the Wazau hardness tester the load is applied by a hand-driven screw (1) and measured by an elastic precision ring dynamometer (2) and dial (3) which is graduated in 10 kg. divisions. Three revolutions of the pointer represent 3000 kg.

The vertical opening of the press is 4″ and can be quickly adjusted to any smaller distance by inserting blocks (4) of different heights. The supporting table (7) is of the overhung type, in order to accommodate ring shaped pieces.

An innovation in this machine is the arrangement of the hollow bronze screw (5) which is rotated automatically when turning the main screw (1) under small loads. At higher loads, the screws disengage automatically, leaving screw (1) to do the final loading. By this construction, the diameter of screw (1) can be kept reasonably small, enabling the easy operation of the machine. The machine is sold in this country by the Southwark Foundry and Machine Company. It is 21″ × 19″ × 8″ without the handles and weighs 100 lbs.

Damping Tester for the Determination of Internal Friction of Materials

The Foeppl-Pertz damping machine sold by Southwark Foundry & Machine Company, Philadelphia, Pa., consists of a frame (1), hung from the ceiling on a wire (2) about 10 ft. long. This unusual way of mounting the machine is one of the special features which provide the high accuracy needed in determining

the small amounts of work absorbed by internal friction in the specimen (3). The test rod (3) is rigidly clamped at its bottom into the frame (1) by means of heavy screws and carries on its top an oscillating mass (4), which makes a reciprocating rotary movement about the axis of the specimen, twisting the same back and forth. A small pivot (5) avoids any lateral movements, so that the stresses in the specimen are purely torsional. The test itself is started by twisting the mass (4) to a desired amount and holding it in a twisted position by means of adjustable electromagnets (6). Upon breaking the electrical circuit of which the magnets' coils are a part, a free oscillation is produced. The stylograph (7) attached to the mass (4) records a damped free vibration diagram on the chart moved by the clockwork (8).

These curves are obtained in a few minutes and represent the damping characteristic of the material which can be replotted in the form of diagrams, showing the amount of work absorbed in relation to the rate of stress. The overall dimensions are 24″ × 12″ × 10″ and the weight is 160 lbs.

(Continued on Page 30)

The Aluminium-Brasses. R. GENDERS. *Journal of the Institute of Metals*, Vol. 43 (1930) pages 163–186.
Includes discussion. See *Metals & Alloys*, Vol. 1, Oct. 1930, page 791. (2)

Properties of Strontium-Tin Alloys. K. W. RAY. *Industrial & Engineering Chemistry*, Vol. 22, May 1930, pages 519–522.
Thermal diagram, photomicrographs, specific gravity, hardness, rate of corrosion of strontium-tin alloys up to 30% Sr were studied and the results are given. 7 references. MEH(2)

Bearing Metals and Bearings. W. M. CORSE. *Transactions American Society for Steel Treating*, Vol. 18, Aug. 1930, pages 179–203.
Paper presented before the Detroit Chapter of the Society, Nov. 1929. Discusses the properties of good bearing materials and a description of white metals, bronzes and graphite bearing metals. The use of various common tests, factors of design and lubrication are discussed. WLC(2)

Brass and Modern Brass Production. (Messing und Moderne Messingfabrikation.) K. GROTEWOLD. *Zeitschrift für Feinmechanik und Präzision*, Vol. 38, Oct. 17, 1930, pages 1–5.
A short review of the various kinds of brass, either pure copper-zinc alloy or with other metal additions especially for use in the optical industry as they are produced in the Brass Works, Hirsch, Eberswalde, Germany. Ha(2)

A New Silicon-Zinc Alloy. E. VADERS. *Engineer*, Vol. 150, Sept. 26, 1930, page 336.
Abstract of paper read before the Institute of Metals, Sept. 11, 1930. See *Metals & Alloys*, Vol. 1, Dec. 1930, page 898. LFM(2)

Silicon-Copper Alloys and Silicon-Manganese-Copper Alloys. E. VOCE. *Engineer*, Vol. 150, Sept. 26, 1930, pages 335–336.
Abstract of papers read before the Institute of Metals, Sept. 11, 1930. See *Metals & Alloys*, Vol. 1, Dec. 1930, page 899. LFM(2)

White Metals, Brasses and Bronzes. Part 5. E. PERRY. *Metal Industry*, N. Y., Vol. 28, May 1930, pages 225–226.
Special yellow brasses contain in addition to Cu and Zn, Al, Fe, Pb and Sn. Al increases strength of brass and acts as deoxidizer. In all brass mixtures Cu is melted first and Zn last. Mixtures high in Cu should be poured at high temp. while high in Zn at low temperature. Contains a table giving representative brass mixtures. VSP(2)

Manganese Bronzes. *Machinery* (London), Vol. 36, May 29, 1930, pages 261–262.
Describes physical properties and composition of Mn alloys for various purposes as well as Mn and Si bronzes; Mn and Al bronze; and Mn additions to brass. Includes tables giving data on physical tests on Mn bronze in chill cast condition; physical tests of Mn in cast alloys; and typical Mn bronze castings. (2)

Aluminum Sheet Production. ROBERT J. ANDERSON. *Metallurgia*, Vol. 2, Sept. 1930, pages 173–176; Oct. 1930, pages 211–214; Vol. 3, Nov. 1930, pages 4–8.
Bibliography of 12 references. Lists sizes, gages, tolerances, tempers and compositions of aluminum and alloy sheets commercially produced. JLG + GTM(2)

Properties of Lead-Bismuth, Lead-Tin, Type Metal and Fusible Alloys. J. G. THOMPSON. *Bureau of Standards Journal of Research*, Vol. 5, Nov. 1930, pages 1085–1107.
The tensile strength, hardness and elongation of a number of lead alloys have been determined and are presented herewith. Data on the solidification characteristics and on the resistance to compression of some of the alloys also are presented. The alloys studied are divided into 4 classes: (1) Binary alloys of lead and bismuth, (2) binary alloys of lead and tin, (3) type metals, with and without the addition of small amounts of bismuth, and (4) fusible alloys of bismuth, lead, tin and cadmium. The data are presented both in tabular form and in graphs. (2)

A New High-Strength Aluminum Alloy (Hyblum). ARCHIBALD BLACK. *Airway Age*, June 1930, page 784.
In recent years duralumin has won favor with aircraft designers. Now a new alloy, under the market name of Hyblum, has been invented. It weighs slightly less than duralumin and its cost is appreciably lower on account of the facility with which it can be rolled. Tests made upon Hyblum indicate, writes the author, that the material possesses qualities desirable in airplane construction. It has more ductility and resists corrosion from salt water better than the commercial grades of duralumin. (2)

An Air-Hardening Copper-Cobalt Alloy. CYRIL STANLEY SMITH. (American Brass Co.) *Mining & Metallurgy*, Vol. 11, April 1930, pages 213–215.
Experiments carried out by author on some Cu-rich Cu-Co alloys showed very marked air-hardening properties. Alloys used contained from 2 to 5% Co and hardened by quenching from above 850° C. If alloy containing from 1 to 5% Co is quenched rapidly from a high temperature at which it is pure α, it will be retained in this condition and remain a homogeneous solid solution at room temperature. Tabulates results of rate of cooling from 900° C. on hardness of a Cu-Co alloy, 3.58% Co. Formation of sub-scale seems to be due to diffusion of O through solid metal, resulting in formation of CoO. VSP(2)

PROPERTIES OF FERROUS ALLOYS (3)

A New Case-Hardening Steel. *Automobile Engineer*, Vol. 20, June 1930, page 204.
Description of a free cutting, case-hardening steel produced by the British Rolling Mills, Ltd., Tipton, Staffs and known as Brymill C. H. 2. Claimed to machine well at high speeds and yet is not brittle and is suitable for case-hardening. RHP(3)

Rustless Chromium-Manganese Steels Have Deep-Drawing Qualities. FREDERICK M. BECKET. (Electro Metallurgical Co.) *Iron Age*, Vol. 125, May 15, 1930, pages 1468–1470.
Includes discussion. Takes up chiefly Cr-Mn steels with 10 to 30% Cr, 3 to 30% Mn, 0.05 to 2% C, 0.02 to 3% Si, 0.10 to 0.5% Ni, max. P 0.025% and S 0.01%. Ingots varying from 2 × 2½ × 6 in. to 6 × 6 × 18 in. and 8 × 8 × 31 in. Steels containing more than 16% Cr are markedly changed by increasing additions of Mn. About 6% Mn changes physical properties of this type of steel. Steel of low C content, as Mn increases have greater elongation and area reduction. Experimental work on deep drawing showed that for a given Mn content the low C steels are superior. The high Cr-Mn steels (over 20% Cr) possess greater resistance to attack by a larger number of chemical substances. For hot rolling purposes temperatures between 1200° and 900° C. were found satisfactory. Cr-Mn steels will withstand greater amount of cold work than Cr steels. For pickling a solution of 1–2% HF and 5–10% HNO_3 used between 50° and 70° C. is suitable. Successful deep drawing has been performed on low C, 17 to 18% Cr steels, containing 7% Mn. Copper addition to Cr-Mn steels enhances their properties. VSP(3)

A New and Ingenious Direct Steel and Metallic Process. *South African Mining & Engineering Journal*, Vol. 41, Part 1, April 19, 1930, page 198.
Pulverized ore and coal are repeatedly showered through hot reducing gases while descending by gravity through an inclined rotary kiln. The product is discharged to an electric furnace where it is showered through the arc. Physical tests on the resulting steel are given. AHE(3)

Recent Investigations in Cast Steel. (Neuere Untersuchungen an Stahlguss.) UDE. *Zeitschrift Verein deutscher Ingenieure*, Vol. 74, Oct. 4, 1930, pages 1399–1401.
Review on some tests of notch-toughness and tensile strength of cast steel at higher temperatures, up to 500° C., and different heat treatments. Curves and 5 references are given. Ha(3)

Alloy Steel Castings. J. GALIBOURG. *Technique Moderne*, Vol. 21, Dec. 1, 1929, pages 754–755.
Abstract of a paper presented at the Oct. 1929 meeting of the 8th Foundry Congress in Paris. (3)

Nickel-Copper-Chrome Cast Iron. (Ueber Nickel-Kupfer-Chrome-Gusseisen.) M. WAEHLERT & H. OSTERMANN. *Chemische Fabrik*, Sept. 24, 1930, pages 377–378; Oct. 1, 1930, pages 386–388; Oct. 8, 1930, pages 402–404.
Paper presented before the "Dechema" in Frankfurt a.M. contains 3 references. Ni-Cu-Cr cast iron or "Nimol" is made by adding about 20% monel metal scrap and 2 to 4% Cr to cast iron, in some cases as high as 20% Cr. The Ni:Cu ratio is 2:1. Nimol is austenitic, non-magnetic, machines as well as cast iron and resists corrosion very much better than cast iron. Comparative tests were made on 15 compositions of unalloyed, low alloy and high alloy cast iron on various Si and C contents. Brinell hardness of Nimol is lower than cast iron. The 13% Ni iron consists of austenite and martensite. With rising Ni content the solubility of Cu in cast iron increases. Summary of corrosion tests:

Relative loss in weight per unit of surface and time

	Nimol	Unalloyed Iron	Cast Brass	Bronze 90 Cu –10 Sn
5% H_2SO_4 at 20° C.	1	475	1.12	1.08
5% H_2SO_4 + 5% H_2O_2 at 20° C.	1	25.4	1.18	1.22
10% H_2SO_4 at 95–100° C.	1	1.95	.15	.15
60° H_2SO_4 at 95–100° C.	1	1.95	—	.08
5% HCl	1	185	13	24
25% acetic acid	1	400	2.75	2.22
Sea water	1	5	.1	2.15
20% NaCl spray	1	2.9	.27	.08

Annealing at 650° C. makes Nimol magnetic and martensitic, except Mixture No. 13, containing 5% Ni and 6% Cu. At 850° C. the unalloyed irons change to ferrite and the surface oxidizes. After annealing at 925° C. Nimol hardly oxidizes, and has very little growth, while unalloyed cast iron oxidizes badly. Mixture No. 13 still remains austenitic and its hardness does not change. Unalloyed irons soften in annealing while Nimol hardens at the lower and then softens at the higher temperatures. Tested at elevated temperatures the tensile strength of 20% Nimol falls off evenly. Nimol can be poured at 1300–1350° C. It welds easily by autogenous and electric process. It is especially useful as a corrosion and heat resisting alloy and is cheaper than brass and bronze. CEM(3)

Gray Iron Possesses Valuable Engineering Properties. Part VI. *Foundry*, Vol. 58, July 1, 1930, pages 94–97.
The most commonly used test for foundry Fe is the transverse strength test. Ultimate fiber stress for gray Fe is shown by modulus of rupture which is calculated from transverse test values. Wide use is made of arbitration test bars of fixed dimension for comparative testing. Minimum test values for various grades are:

	Breaking load lbs.	Deflection inches
Gray iron, light	1500	0.20
Gray iron, medium	1750	0.20
Gray iron, heavy	2000	0.20
Soil pipe and fittings	1500	0.20
High test gray iron	2500	0.24
British grade A	1950	0.15
British grade C	1600	0.12

Employment of moduli of rupture calculations appears the only logical means of making comparisons of various Fe in various shapes and sizes of test bars. In true gray Fe the intrinsic strength of metal in a series of bars decreases as the cooling rate becomes slower. Slow cooling promotes more complete graphitization and coarser grain, consequently weaker metal. The stronger Fe has higher moduli of elasticity in transverse as well as in tension. Gives number of graphs and tables. VSP(3)

Data on Manganese Structural Steels with Chromium Additions. A. B. KINZEL & W. B. MILLER. *Transactions American Society for Steel Treating*, Vol. 18, July 1930, pages 55–69.
A paper presented before the semi-annual meeting of the Society in New York, Feb. 7–8, 1930. Includes discussion. A series of Cr-Mn steels of 0.08–0.50% C, 0.6–1.8% Mn with additions of 0.3–1.1% Cr were studied showing a beneficial effect of Cr in increasing the ultimate strength without loss of ductility. The results obtained show such steel to have possibilities in the general structural field, in the as rolled or normalized condition. A practical application to the construction of a welded pressure vessel is discussed. In discussion, the use of such a composition for seamless tubing is touched upon by A. V. DeForest (Spang Chalfant Co.). Mr. W. J. Merten mentions the difficulties in heat treating heavy sections of such steel and the effect of Cr on the grain refinement. WLC(3)

The Physical Properties of Pure Chrome-Steels and Tungsten-Steels. (Die physikalischen Eigenschaften von reinen Chrom- und Wolframstählen.) F. STÄBLEIN. *Zeitschrift Verein deutscher Ingenieure*, Vol. 74, April 26, 1930, page 541.
Tests with a chrome-steel of 24% Cr and a tungsten-steel of 28% W showed the following after annealing several hours at 800° C.: the density follows closely the one determined by the rule of mixing, i. e., it is reduced for each 1% of Cr by 0.0083, increased for each 1% of W by 0.048. The specific resistance is increased for each 1% Cr by 0.062, by each 1% W by 0.017 Ohm/mm.^{2} up to 2% Cr or 7% W. For higher percentages somewhat different values are obtained. Heat conduction of pure iron is reduced by almost half by the addition of 5% Cr and reaches a minimum at 17% Cr of 0.05 cal./cm. sec. degree. For about 14 to 30% W the heat conductivity is about 0.09 cal./cm. sec. degree. W produces a very high remanence. The thermal expansion did not give very simple relations. See *Metals & Alloys*, Vol. 1, Jan. 1930, page 337. Ha(3)

Alloy Steels for Locomotive Construction. W. ARNOLD JOHNSON. *Proceedings Institution of Mechanical Engineers*, No. 5, 1929, pages 1087–1097.
Abridged from a paper read before the Graduates Section, Northwestern Branch, in Manchester, Oct. 11, 1928. Even after the best heat-treatment, those carbon steels which can be suitably worked and manufactured, can only be relied upon to give a tensile strength of about 55 tons/in.^{2}. Carbon steel of this tensile strength usually has low impact resistance. Alloy steels may be treated to give a tensile strength of 40–110 tons/in.^{2} and still give satisfactory impact values. The effect of vanadium in steel on the dynamic strength or resistance to fatigue is even greater than on its static properties. Discusses chromium-vanadium steel, "Vibrac" steel, which is a nickel-chrome-molybdenum steel, German steel of 0.1–0.15%C and 0.67–1.5% Si, and manganese steel. Corrosion of boilers, strength of connecting rods and other locomotive parts and the materials best suited to the place are discussed. RHP(3)

New Use for High Speed Friction Saws

By associating methods in industry, many important problems are solved. It was through such association that a high speed friction saw was put in service for cutting off casting risers.

A representative of the Harrison Company visited a plant recently, where a Ryerson Friction Saw was cutting through heavy structurals. The ease and speed with which the cuts were made led him to believe that casting risers could also be cut off by this process. Several tests were made and his convictions proved correct, for this company has not only increased production through the use of The Ryerson Friction Saw, but it has also saved considerable expense by eliminating all grinding on many jobs.

The cost of grinding wheels is an important item and when the torch burning process is used this cost cannot be avoided. About $^1/_4$ inch of the riser remains to be ground because if the torch were allowed to cut flush with the casting, part of the casting would be burned. In most cases where a high speed friction saw is used a flush cut is accomplished.

The illustration shows the high speed friction saw installed at the Harrison plant.

New Metal Microscope

The construction of this microscope, marketed by the Clay-Adams Company, is based on the Le Chatelier principle. It combines the principle of the inverted metallurgical microscope with the ease and convenience in handling of the usual type without in any way affecting the optical advantages of the former.

Its optical features are the same which are found on large metallographic benches with the exception that the totally reflecting prism used for visual examination is fixed so that the same ocular serves for both examination and photography. To accomplish this the illuminating system and the microscope itself, which are connected in one rigid body, are made to rotate in the vertical plane so that after location of a desired spot the image obtained can be projected in any given direction either onto the table or a screen or photographic plate. The light source is a special 6 volt lamp. The optical system is good, both in resolving power and strength of light. A properly exposed negative at 2000 magnifications calls for about 30 seconds exposure time. Projected on a screen until the field is four feet diameter the image is perfectly bright and what is even more important, the image is perfectly flat without any distortion at the edges whatever. The microscope is very simple to operate.

Magnification 100 × Magnification 2000 ×
Micrographs of same sample of cast iron reduced to $^1/_3$ of the original.

Once adjusted the illuminating system does not require any attention and final focusing is reduced to a few seconds time. The objective remains stationary while the stage, to which the specimen is fastened with a spring clamp, is moved both by the coarse and fine adjustment screws.

◆ ◆ ◆

Metallographic Polishing Machine

The new Aminco automatic metallographic polishing machine has a polishing head covered with a suitable polishing cloth. This head is mounted on vertical spindles, running in ball bearings, and is driven by a belt from a motor.

Resting on the polishing disk may be seen 3 specimens in their brass ring holders. These holders float on the polishing cloth and change their positions slightly as the contour of the cloth changes. The specimens are held lightly against the cloth by spring rods which bear on the exact centers of the specimen holders. At the top of each specimen spindle is a rigidly attached gear, which meshes with an eccentric gear. This eccentric gear gives the motion to the specimens which so largely contributes to the perfect work done by the machine. It is accomplished as follows:

The eccentric gear is driven through a speed reducer and as it rotates it causes the 3 specimen holder gears also to rotate. Being meshed with an eccentric gear, the 3 specimen holder gears not only rotate on their own axes, but they continually oscillate toward and away from the center of the polishing disk. Thus the specimen has the following motion:

It is free to move vertically within limits. It rotates on its own axis. It is slowly moved from the outer edge to the center of the polishing disk and the result of this motion is a perfectly polished specimen.

The new Aminco automatic metallographic polishing machine eliminates the "personal equation" and produces a high grade of work. It will very quickly save many times its cost in any metallurgical laboratory.

This machine will polish 3 different specimens at one time. The specimens need not even be of the same metal, providing they fall into such a classification that they can be polished with the same material, and on the same cloth. This machine is manufactured by the American Instrument Co., Washington, D. C. and is modeled on the one designed at the Bureau of Standards and described in METALS & ALLOYS, Vol. 1, Nov. 1929, pages 226–230.

The Corrosion Resistance of Al-Dur-Bra. *Metal Industry* (London), Vol. 37, July 18, 1930, pages 59–61.

Al-Dur-Bra is an Al brass cast by the Durville process composed of 76% Cu, 22% Zn and 2% Al. It is a homogeneous solid solution—the α solution—of the ternary system Cu–Zn–Al. Mechanical properties are superior to brasses of 70:30 type. Due to its ductility it is easily worked, hot or cold. Its corrosion resistance is due to the fact that during annealing or hot working, it oxidizes or scales very little. Gives various applications. Its manufacture is covered by British patent No. 308,647. VSP(4)

High-Pressure and High-Temperature Steam for Locomotives. C. F. Hirshfeld. *Preprint, American Society of Mechanical Engineers*, Dec. 1–5, 1930, 7 pages.

Certain experiences and observations regarding the behavior of metals and the boiler circulation under extreme conditions are given, and these are followed by speculations regarding the possible lines of development of locomotives. (4)

High-Performance Gasoline Aircraft Engine—Its Problems of Fuel, Oil and Materials of Cylinder Construction. S. D. Heron. *Transactions, American Society of Mechanical Engineers, Aeronautical Engineering*, Vol. 2, Oct.-Dec., 1930, pages 233–253.

Section 4 of this article is entitled: Corrosion and Attack due to Fuel in Aircraft Engines. In this section the author discusses cylinder corrosion, valve corrosion and attack, exhaust disposal system, valve-seat insert attack, valve gear and spark plugs. (4)

Wear Oxidation, a New Component of Wear. Max Fink. *Transactions, American Society for Steel Treating*, Vol. 18, Aug. 1930, pages 204–212.

The summary of a thesis for Dr.-Ing. degree at Technische Hochschule Berlin-Charlottenburg, Germany. Includes 7 references. The oxidation accompanying wear as previously observed is discussed. Various wear testing machines are described. Tests on an Amsler wear testing machine excluding oxygen from the specimens resulted in no loss of weight. The 3 essential components of wear are (1) mechanical removal of particles, (2) cold hardening, (3) wear oxidation. WLC(4)

Corrosion and Protective Films. A. C. Hanson (Rock Island Arsenal Laboratory). *Industrial & Engineering Chemistry*, Vol. 22, May 1930, page 554.

As a result of two microscopic observations of the action of water containing respectively oxygen and carbon dioxide, on polished steel, it is thought that the first action is given by the equation $Fe + 2H^+ (ionic) + 2(OH)^- = Fe^{++} (ionic) + 2(OH)^- + H_2$. A film of ferrous hydroxide protects the metal. Carbon dioxide then reacts with this film, forming soluble ferrous acid carbonate, which is later precipitated as ferric hydroxide after dissolved oxygen has acted upon the ferrous salt. MEH(4)

Report of the Commission on Testing Metals and Alloys at Elevated Temperatures (Comptes-Rendus des travaux de la commission des essais à chaud des metaux et alliages). J. Galibourg. *Revue de Metallurgie*, Vol. 27, Aug. 1930, pages 439–442.

French Association for testing materials proposed a few years ago a tentative organization for investigation of the properties of metals at elevated temperatures. Its constitution is given. JDG(4)

The Influence of Copper on the Rusting Reaction of Copper Steels in Atmosphere and in Different Waters. (Ueber den Einfluss des Kupfers auf den Rostvorgang gekupferten Stahles an der Atomsphäre und in verschiedenen Wässern.) C. Carius & E. H. Schulz. *Mitteilungen aus dem Forschungs-Institut der Vereinigte Stahlwerke Aktiengesellschaft Dortmund*, Vol. 1, No. 7, 1929, pages 177–199. 20 references.

Copper steel when in water solutions forms a copper oxide film which prevents further corrosion. See *Metals & Alloys*, Vol. 1, March 1930, page 426. GTM(4)

Metallurgy and Power Industry. J. B. Romer. *Metals & Alloys*, Vol. 1, Dec. 1930, pages 868–870.

Boiler materials must be capable of withstanding high stresses, high temperatures and extremely corrosive conditions. Super-heater equipment must withstand a loss of strength at high temperatures. Creep tests permit a measurement of this property. Austenitic chrome nickel alloy yields excellent service for superheater construction. The material is also widely applicable in the oil industry. No. 1100 metal is useful for boiler parts such as hangers which require huge corrosion resistant properties. ESC(4)

The Problem of Corrosion of Ferrous Metals. V. Sallard. *Technique Moderne*, Vol. 21, Nov. 1929, pages 673–681.

A general review of the causes of corrosion and of corrosion and heat resistant steels and alloys. Among the materials considered are 3% nickel steel, Invar, nickel-chromium-iron alloys (Ni 8.0, Cr 17.0). Corrosion resistant cast iron (0.85% Ni) is also briefly discussed. (4)

The Open-Air Corrosion of Copper. Part II. W. H. J. Vernon & S. Whitby. *Engineer*, Vol. 150, Sept. 26, 1930, page 335.

Abstract of paper read before the Institute of Metals, Sept. 11, 1930. See *Metals & Alloys*, Vol. 1, Nov. 1930, page 843. LFM(4)

Influence of Cyclic Stress on Corrosion. D. J. McAdams, Jr. (U. S. Naval Eng. Exp. Station). *Technical Publication* No. 329, *American Institute of Mining & Metallurgical Engineers* (1930) 42 pages.

Endurance samples were corroded in water sprays while undergoing various alternating stresses, and their apparent endurance limit then determined. The alloys tested were carbon steels, alloy steels, monel metal, brass, duralumin and an Al-Mn alloy. The results are completely reported in the form of curves. The damage done is estimated from the difference in endurance limit between the corroded and uncorroded samples. Even very low alternating stresses increase the damage by corrosion. For steels and Al alloys stresses as low as 2000 lbs./in.^{2} have an appreciable effect. Corrosion resistant alloys are damaged if the stress-corrosion time is sufficiently long. Contains 13 references. JLG(4)

Corrosion and Metal Protection in Boiler Practice. R. Stumper. *Metals & Alloys*, Dec. 1930, page 895–896.

A translation. See *Metals & Alloys*, Vol. 1, Dec. 1930, page 902. ESC(4)

The Effect of Brines on Metals. (Die Einwirkung von Kühlsolen auf Metalle.) T. Liepus & H. Osterburg. *Metallwirtschaft*, Vol. 9, Oct. 31, 1930, pages 904–906.

The usual brines consist of NaCl, $MgCl_2$, $CaCl_2$ solutions, or mixtures of these. The sediment which accumulates in these solutions is due to impurities. The attack of brines on metals consists of both electrolytic action and direct corrosion. The action of 5 solutions made from chemically pure salts and of one commercial product on Fe, Cu, Zn, Sn and Al was studied and some of the results are described and shown by curves. CEM(4)

Castings that Withstand Heat and Corrosion. W. F. Furman. (Duraloy Co.) *Iron Age*, Vol. 125, May 1, 1930, pages 1277–1280, 1359.

Ni-Cr coatings for use at high temperatures were first introduced in 1914. A typical analysis was 60% Ni and 12% Cr, the remainder mostly Fe. Castings in which Ni predominates are used for temperatures of from 2100° to 2200°F. Casting problems are many. Melting is done usually in arc-type electric furnaces. Correct pouring temperatures are important. The fluid metal solidifies much faster than Fe or steel. High Cr-Fe alloys are much used in corrosion resisting field. VSP(4)

RAMET

YOU have never used a cutting metal like RAMET (Tantalum Carbide)—it's something *entirely new!* And in performance, RAMET is setting an entirely new pace.

RAMET has advantages found in no other tool metal. For instance, its low thermal conductivity *keeps tools cool*—even when chips are red hot!

Try RAMET on your job—whether it be "unmachinable" steel, or fast production work where seconds count.

Full information upon request.

FANSTEEL PRODUCTS CO., INC.
NORTH CHICAGO, ILL.

RAMET
is the Registered Trade Mark of the original Tantalum Carbide, developed and manufactured only by Fansteel Products Company, Inc.

Bending Machine for Static and Repeated Reversed Loads

A knowledge of the endurance properties of all machine parts subjected to repeated stresses, is very important. Consequently endurance or fatigue tests become more and more essential. An ideal fatigue machine should permit the different "short time" determinations of the fatigue limit to be made. This limit is defined as that stress that can be withstood for an indefinite number of stress cycles without fracture of the specimen. The Foeppl-Heydekampf machine sold by the Southwark Foundry and Machine Company, Philadelphia, Pa. will make the above tests using a test piece of simple shape.

The frame of the machine (4) is a light alloy casting into the lower part of which is built a switch panel containing all necessary operating and controlling instruments. The bottom of the specimen (1) is rigidly clamped to the frame (4) and the top is connected with an oscillating mass (2) of considerable length. Usually the tests are run with 2 specimens at a time. The machine may, however, be used equally well for a single specimen. Two thin flat springs (3) are mounted in a similar way between frame (4) and oscillating mass (2), but they are not intended to break, being thinner than the specimens. The springs (3), the specimens (1), and the mass (2) form a mechanical swinging system, which is excited by 2 pairs of electromagnets (6a) and (6b), alternately giving impulses to the mass (2). The magnets are switched on and off by a special lever contact device, not visible in the illustration. The switch lever is moved by the mass (2), due to friction, so that the number of impulses agrees with the natural frequency of the oscillating system. The exciting magnetic forces change their direction in the end position of the swing. Once slightly touched by hand, the system starts and keeps on swinging "in resonance" and requires very low power (not over 0.3 kw.). The amplitude of the oscillation is varied by changing the current in the electromagnets (6) by adjusting the rheostat (7).

The oscillation is a rotary reciprocating movement of the mass about an axis through the middle of the specimen. The angular amplitude can be read from special visual reading devices (5) attached to the ends of the mass (2). Both devices give the same reading, checking each other. The stress in the specimens is proportional to the amplitude within the range of Hooke's law. It can be directly figured from the readings on the scale (5). If Hooke's law is exceeded, the exact determination of the stress must be made by an additional static loading arrangement furnished with the machine. The pulleys (9) and some other weighing and measuring equipment not shown in the figure permit finding the actual stress strain relation, thus eliminating the usual error, due to figuring the stress according to Hooke's law. This static weighing device also eliminates the errors based on the assumption that the clamps are rigid, since the amount of yield in the grips is measured in the static test.

The stress is constant over the full gage length of the specimen. The acceleration forces during the oscillation are pure moments. The center of gravity of all moving parts is in a stationary position, so that a pair of accelerating forces is always generated. The stress distribution over the length is as uniform as the one in tensile specimens and the simple shape of the latter without reduced sections or tapers is readily applicable for fatigue tests on this machine. The failures are, therefore, not restricted to a certain part of the specimen, but occur where the weakest point of the material happens to be, thus clearly revealing any lack of uniformity of the material tested. The uniform stress distribution is also applied in the static bending test.

The number of cycles is counted by an electrical counter (8) driven by a small synchronous motor in series with the pulsating current line feeding the electromagnets. As a matter of fact, the number of electric impulses is counted, which, however, is equal to the number of oscillations or stress cycles, due to the resonance principle applied. An automatic adjustable contact mechanism stops the machine after a failure.

The specimens do not rotate and have an unusually large part of their total volume subjected to the testing stress. The machine is, therefore, particularly convenient for any of the proposed "short time" tests, e. g., rise of temperature method or electrical resistance method. It also permits with more than the ordinary facility the study of the mechanical hysteresis effect to which property the names "damping capacity" or "dynamic ductility" have also been applied. The machine weighs 180 lbs. and is 22″ × 30″ × 39″.

Ramet—A New Cutting Material

Ramet is a new cutting material developed by the Fansteel Products Co., Inc., Chicago, Ill.

As this material is produced at present, metallic tantalum, in a powdered state, is converted to carbide. The carbide is ground to extreme fineness in a mill, addition of a certain amount of nickel being accomplished at this time. The ground powder is then pressed into the shape of finished blanks and heat treated.

The blanks are brazed to steel shanks, then the tools ground to the desired finished shape.

Tantalum carbide is not easily "wet" with other metals. While this necessitates a special operation before the material can be brazed, it is of great advantage to the ultimate user, especially when machining steel, as hot chips will not alloy with the tool. Therefore no pitting or abrading takes place.

The special operation for brazing Ramet consists of a special heat treatment in a controlled atmosphere, followed by nickel plating. In this condition the material can be brazed easily with pure copper or any of the common brazing alloys.

An interesting characteristic of Ramet is its high melting point, which is approximately 4400° C. Metals of the tantalum-columbian-vanadium group apparently produce carbides with melting points higher than those of the parent metals; while tungsten carbide melts at 2700° C., far below the melting point of tungsten metal.

The ultimate tensile strength of Ramet is 250,000–300,000 lbs./in.^{2} This factor is watched very carefully, and a sample of each lot of Ramet is tested by the laboratory.

Another outstanding characteristic, and perhaps the most useful from a tool standpoint, is low thermal conductivity, which results in both the tool and the work remaining remarkably cool, even when turning red hot chips. Comparative tests have been made where an alloy tool was permitted to run until the tip became red hot and the shank began to turn blue. Without changing the feed or speed, a Ramet tool was substituted, and allowed to operate for the same length of time. Upon stopping the machine, the Ramet tool could be handled with bare hands. This is explained by the fact that when a tool is sharp, practically the only heat generated is within the chip, the only heat reaching the tool or work being that which the tool conducts away from the chip.

This low thermal conductivity is of advantage to users because it keeps tools, machines and work cool. It is of advantage to tool makers because it practically eliminates the difficulty of tips loosening because of softened brazing. Experiments have been made successfully with tools brazed with zinc, which held perfectly. In fact, in all the tests which have been made with Ramet tools, there is not yet a single case of failure due to softened brazing.

Tests seem to indicate a great deal of success for Ramet in the machining of steel, cast iron, bronze, aluminum, duralumin and synthetic plastics.

◆ ◆ ◆

The need for avoidance of embedded particles of iron or iron oxide on polished austenitic corrosion-resistant steels and rustless irons has led to the introduction of polishing pastes in which rouge or other materials containing iron oxide are carefully avoided. One of these, called Alumilite Paste has been developed by the E. Reed Burns Mfg. Corp., Brooklyn. It is said to be non-magnetic and is made solely of artificial abrasives of different grain sizes, combined with the correct amount of lubrication to meet proper polishing wheel speeds.

It is generally used on a sewed rag wheel following the last dry "set-up" abrasive wheel in order to produce the "bottom" so necessary to subsequent high mirror finishes.

It may also be used on a Tampico Bristle Brush to produce a brush finish.

◆ ◆ ◆

The Institute of Metals has just issued the first number–dated January 1931–of its new monthly Journal containing original articles, Institute news and abstracts of the world's metallurgical literature–96 pages in all. Hitherto the Journal has appeared in the form of half-yearly volumes divided into two Sections: "Proceedings" and "Abstracts." Henceforth the volumes issued each June and December will contain only "Proceedings," and the "Abstracts" will appear monthly–to be re-issued in volume form at the end of each year.

Cadmium versus Zinc Plating as Rust Preventives. W. S. PATTERSON. *Chemical Age*, Vol. 23, Aug. 2, 1930, Metallurgical Section, pages 7–8.

A condensation of a paper, "The Resistance of Electrodeposits to Corrosion, with Special Reference to Cadmium and Zinc." before the Electroplaters' and Depositors' Technical Society. Deposits of cadmium and zinc on 0.18% carbon steel were made from the following solutions:

Zinc Solution		*Cadmium Solution*	
Zinc sulphate	300 g.	Cadmium oxide	24 g.
Sodium chloride	13 g.	Sodium cyanide	66 g.
Boric acid	20 g.	Water	1 l.
Aluminum sulphate	26 g.		
Dextrine	13 g.		
Water	1 l.		

The thickness of the coatings were 0.65 mil. for cadmium and 0.70 mil. for zinc. They were then exposed (1) in an indoor unpolluted atmosphere, (2) swimming pool atmosphere containing chlorine, and (3) outdoor atmosphere.

(1) Mean weight increments, milligrams

	90 days	250 days
Zinc plated	1.1	2.7
Cadmium plated	1.8	2.0

(2) Mean weight increments, grams/in.²

	96 days	175 days	272 days
Zinc plated	0.59	0.81	1.5
Cadmium plated	0.59	1.1	2.8

(3) Mean loss in weight mg./in.²

	93 days	185 days	267 days
Zinc plated	2.4	14.8	19.6
Cadmium plated	9.7	43.9	72.7

A check on (3) follows:

Loss in weight, mg./in.²

	76 days
Zinc plated	8.2
Cadmium plated	21.4
Pure zinc	6.5
Pure cadmium	17.7

The author states that cadmium plating is satisfactory for indoor exposure but that zinc is to be preferred for outdoor exposure. The cause of the more severe attack of the cadmium plated material outdoors he considers to be the formation of soluble corrosion products with the cadmium coating as opposed to the formation of insoluble corrosion products with the zinc coating. VVK(4)

Corrosion of Nitrided Steels. LEON GUILLET & MARCEL BALLAY. *Iron Age*, Vol. 125, May 22, 1930, page 1531.

In a report to the Paris Academie des Sciences, Dec. 1929, the authors discussed corrosion resistance of steels case hardened by ordinary methods and by nitriding. See *Metals & Alloys*, Vol. 1, Oct. 1930, page 792. VSP(4)

Protective Electroplating on Aluminum Alloys. *Metallurgist*, July 1930, pages 103–104.

An extended abstract of a paper before the Electroplaters' and Depositors' Technical Society on "The Protection of Aluminium and Its Alloys by the Deposition of Zinc," by Dr. H. C. Cocks. The following metals were plated: commercial aluminum, commercial British duralumin, the sand-cast aluminum alloys L5, L11, L24 and D.T.D.25, mild steel, copper and brass. A large number of the test pieces were subjected to corrosion tests, the entire investigation extending over 2 years. Both sulphate and cyanide baths were investigated. It was found that practically all the deposits from the sulphate baths gave very good protection to aluminum and aluminum alloys. The protection afforded by the cyanide baths, although good, was not equal to that from the sulphate baths. The ammonical zinc cyanide bath showed no appreciable superiority over the sodium zinc cyanide sodium zincate bath. The bath recommended for aluminum and its alloys is zinc sulphate (crystal) 145 g./liter, sodium acetate (crystal) 35 g./liter and gum arabic 1 g./liter. A current density of 30 amp./ft.² should be used with the solution at pH 4.0. VVK(4)

Thickness of the Oxide Film which Produces Temper Colour on Iron. MASAO KURODA. *Scientific Papers, Institute of Physical & Chemical Research*, Vol. 14, Sept. 20, 1930, pages 145–152.

A piece of mild steel which had been heated to about 400° C., the surface tarnished to dark blue, was polished so slightly that the steel surface does not appear. The color of that part became a yellowish brown which corresponds to the temper color at a lower temperature. According to the depth of the groove produced by the polishing, the temper color was changed from the former to the latter. The depth was measured by making a light beam interfere in the space between that plane and an optically flat surface of glass, and the value of 40.5$\mu\mu$ was obtained. On the other hand, a series of temper colors was made by heating pieces of mild steel to different temperatures. The temper colors were subjected to photometric measurements and the wave lengths of the ray having the maximum intensity in the beams of dark blue and yellowish brown were 450$\mu\mu$ and 630$\mu\mu$, respectively. The refractive index for the film (n = 1.70) was calculated from these wave lengths and the depth of groove. This value practically coincides with that of iron oxide, showing that the interference theory agrees with the results of the experiment. TS(4)

The Automatic Maintenance of Solid-Liquid Equilibrium in a Metal. PAUL A. ANDERSON. *Review of Scientific Instruments*, Vol. 1, Dec. 1930, pages 764–767.
Article describes a method for automatically maintaining a bath of zinc in two-phase equilibrium through the increase in specific resistance attending isothermal fusion. (5a)

The Constitution of the Alloys of Iron with Silicon. JOHN L. HAUGHTON & MAURICE L. BECKER. *Iron & Coal Trades Review*, Vol. 120, May 9, 1930, pages 759–760; *Foundry Trade Journal*, Vol. 42, May 22, 1930, pages 379–380.
Abridged from a paper before the British Iron and Steel Institute, May 1930. See *Metals & Alloys*, Vol. 1, Oct. 1930, page 794. VSP + RHP(5a)

The Solubility of Gold in Mercury. II. ARTHUR A. SUNIER & CHESTER M. WHITE. *Journal American Chemical Society*, Vol. 52, May 1930, pages 1842–1850.
Amalgams as dilute as 0.3% have been prepared and analyzed, by a method described, with a precision approaching one part in a thousand. The solubility found is 0.1306 atomic % at 20°, which is about 2 oz. per 100 lbs. of Hg. MEH(5a)

Graphite in Cast Iron ARCHIBALD ALLISON. *Foundry Trade Journal*, Vol. 42, June 5, 1930, pages 417–418.
Physical properties of cast Fe are largely governed by the quantity and form of graphite it contains. Coarse graphite produced in pig Fe by smelting does not completely dissolve, but remains as an emulsion in molten metal, and in solidification forms nuclei for the formation of coarse graphite flakes. This is based upon the presence of kish. Graphite in pig Fe of very open fracture appears as coarse flakes in a matrix of ferrite. Precipitation of graphite is produced by sulphide crystals acting as nuclei. A radial structure in the nodule itself indicates that in the annealing process dissociation of carbide and precipitation of graphite originated in center proceeding outward. VSP(5a)

The Structures of the High Chromium Stainless Steels and Irons. E. C. BAIN (U. S. Steel Corp). *Advance Copy, American Iron & Steel Institute*, Oct. 1930, 26 pages; *Blast Furnace & Steel Plant*, Vol. 18, Nov. 1930, pages 1690–1697; *Fuels & Furnaces*, Vol. 8, Nov. 1930, pages 1531–1535.
Only solid solution Cr, and not chromium carbide, is effective in producing stainlessness. It has been suggested that ferritic Fe-Cr alloys need 15% Cr plus 16 times the C content, to be safely rust-resistant in the annealed condition. C must be held low, or by rapid quenching be held in the martensitic state, or, by addition of another element, as Ni, the steel may be kept austenitic at room temperature. By some of these means the Cr may be almost all held in solid solution so that it is effective. The metallography of these steels, therefore, refers largely to the details of the behavior of the chromium carbide. Equilibrium diagrams for carbonless Fe-Cr, Fe-Ni and Ni-Cr are given, followed by diagrams showing the behavior and constitution of alloys of 14% and 18% Cr with varying carbon content, 18% Cr with varying Ni, and 18% Cr, 8% Ni with varying C. The stability of the carbide, its behavior on heat-treatment and the effect upon corrosion-resistance and embrittlement, are followed through in all these compositions. The hardening of the austenitic alloys by cold work is discussed. The paper is a very concise survey of a complicated subject and will be especially valuable to those wishing a clear general picture of the subject. HWG(5a)

Stability of Cementite and the Various Forms of Carbon. (Om cementitens och de olika kolmodificationernas stabilitetsförhållanden.) G. Phragmen. *Jernkontorets Annaler*, Vol. 114, Aug. 1930, pages 431–442.
Critical review of the literature, the conclusion being that the evidence indicates that cementite becomes stable at higher temperatures. 24 references. HCD(5a)

On the Nature of the Transformations of β-Phase in the Copper-Tin Alloys. 1st Report. HIROSHI IMAI & ICHIJI OBINATA. *Memoirs of the Ryojun College of Engineering*, Vol. III, Aug. 1930, pages 117–135.
Eleven alloys of Cu–Sn system containing 20–33% tin were prepared and the electric resistance-temperature curves and the differential thermal curves were taken with annealed and quenched specimens. The effect of the cooling rate on the structure of quenched specimens was also studied. From these results the authors obtained the conclusions that the eutectoid change of the β-phase proceeds in the 3 steps according to the scheme, $\beta \longrightarrow \beta' \longrightarrow \beta'' \longrightarrow \alpha + \delta$. The quenched specimens show the marked changes at 200°, 250° and 350° C. on heating curves. The first is due to the change $\beta \longrightarrow \beta'$, the second, to that of $\beta' \longrightarrow \beta''$, and the third, to that of $\beta'' \longrightarrow \alpha + \delta$. This view was further confirmed by the change of the electric resistance of specimens during holding at several temperatures. The martensitic structure which is observable in quenched alloys with less than 25% tin is the mixture of β- and β'-phase, owing to the incomplete transformation of the change $\beta \longrightarrow \beta'$. The change taking place at 590° in the β-phase is not due to the change of phase but to that of atomic energy as the A_2 transformation in iron. TM(5a)

The Solubility of Silver in Copper. (Ueber die Löslichkeit von Silber in Kupfer.) F. MÖLLER. *Metallwirtschaft*, Vol. 9, Oct. 24, 1930, pages 879–885.
The solidus line of Cu-Ag alloys at the Cu end was determined by electrical resistance measurements at various temperatures. The greatest solubility of Ag in Cu is 7%. The shape of the resistance-temperature curves is different for different % Ag. Equilibrium weights agree better when determined in cooling than by the same rate in heating. The author's results are compared with those of Hirose, Johansson and Linde and Weinbaum. A procedure for the X-ray study of Cu-Ag alloys is outlined. CEM(5a)

A Note on the Constitution of Cadmium-Zinc Alloys. D. STOCKDALE. *Engineer*, Vol. 150, Sept. 26, 1930, page 337.
Abstract of paper read before the Institute of Metals, Sept. 11, 1930. See *Metals & Alloys*, Vol. 1, Nov. 1930, page 844. LFM(5a)

On the heterogeneous Structure of Martensite. (Ueber die sogenannte Heterogenität des Martensits.) E. MAURER & G. RIEDRICH. *Archiv für Eisenhüttenwesen*, Vol. 4, Aug. 1930, pages 95–98; *Stahl und Eisen*, Vol. 50, Oct. 9, 1930, pages 1431.
The investigation clears up the question as to whether the carbon in quenched steels is uniformly distributed or not. The opinion of a non-uniform distribution is based on the fact that a non-uniform distribution of cementite is found after drawing the hardened steel between 600° and 650° F. Since these findings could be due to concentration changes during drawing, microscopic examinations of hardened hypo- and hyper-eutectoid steels were carried on. In order to obtain clear evidence of possible changes in the distribution of cementite in drawing, certain spots of the hardening structure were examined after drawing at various temperatures. These investigations on a 1.7% C steel and a 0.58% C steel prove that the distribution of cementite is uniform at low drawing temperatures, but differences in the distribution are observed after drawing at high temperatures, which firmly assures that there is a uniform distribution of carbon in the quenched samples. In order to explain the hardening structure of hypo-eutectoid steels, steels with 0.05, 0.12, 0.20, 0.45, 0.58, 0.75 and 0.86% C were studied Two distinct structural constituents could be observed in the steels from 0.45% to 0.86% C after etching with nitric acid, dark colored needles and spots in a bright etching matrix of fine needles. The dark constituent is drawn martensite; the bright constituent non-drawn martensite. The originating of the dark constituent is rendered more difficult by a quicker quench and a higher manganese content. GN(5a)

A Study of the Iron-Chromium-Carbon Constitutional Diagram. V. N. KRIVOBOK (Carnegie Institute of Technology) & M. A. GROSSMAN (Republic Steel Corp.) *Transactions American Society Steel Treating*, Vol. 18, July 1930, pages 1–48.
Paper presented before the 11th Annual Convention in Cleveland, Sept. 9–13, 1929. Includes discussion and 7 references. Previous studies have covered Cr content up to 18% and the present paper deals with the changes in the microstructure of alloys of higher Cr 20–35% and C 0.10–0.60%. The findings of previous work showing a γ-iron loop and the effect of C content on the austenite range are discussed in relation to the observations made on the alloy. Three sets of alloys of 22%, 28% and 33% Cr were studied respectively with C varying between 0.10% and 0.60% and tables of their microconstituents are given. These results are plotted into a ternary diagram. The areas where iron occurs alone, where it occurs with carbide and with austenite are shown. The opposite effects of C and Cr on the promotion or suppression of the γ-range are shown to be the same in these higher alloys as in the lower one previously studied. The paper contains 37 micrographs of the structures observed. An appendix covering a thermal analysis of certain of the alloys by the author is added. WCL(5a)

Structure & X-ray Analysis (5b)

X-Ray Apparatus Used in Portable Setup. *Iron Trade Review*, Vol. 86, Feb. 6, 1930, pages 73–76, 80.
See "X-Raying Large Steel Castings," by Ancel St. John & Herbert R. Isenburger, in *Metals & Alloys*, Vol. 1, July 1930, page 628. MS(5b)

The Application Possibilities of X-Ray Stereogrammetry for the Location of Defects in Testing of Materials. (Die Anwendungsmöglichkeit der Röntgenstereogrammetrie zur Fehlerortsbestimmung bei Materialuntersuchung.) H. WENDT. *Bildmessung und Luftbildwesen*, Vol. 5, Aug. 1930, page 140.
By giving a proper shape to the anode surface Götze succeeded in obtaining an almost point-like source of the rays in the X-ray tube. Several such tubes are described and methods for evaluation of the pictures discussed. Ha(5b)

X-Ray Prevents Foundry Losses. WILBUR S. WERNER. (Kelly-Koett Co.) *Iron Age*, Vol. 125, May 1, 1930, pages 1290–1291; May 15, pages 1466–1467.
Radiographic method is preferred for most metal examinations. First, the film presents more minute details; second, the heavier metals such as Fe, Cu, Sn and their alloys, a lengthy exposure; third, film gives a permanent record. Present limiting thickness of common metals commercially tested: $3^1/_2$ in. of Fe, $2^1/_2$ in. of brass or Cu, 8 or 10 in. of Al or equivalent of any other metal. Steel alloys offer individual problems depending upon their composition. X-rays have assisted in perfection of art of welding. Welded parts are now used where they were considered inapplicable. Fluoroscopic method is confined chiefly to light metals and organic substances, and finding defects in manufactured articles. Ionization testing is not in common use because of its limitations. One of the greatest fields for X-ray inspection is in the examination of fine structure, determination of grain size, crystal structure and orientation, chemical composition and existence of strains. Valuable aid in heat treatment. Gives typical layout for a complete X-ray laboratory. VSP(5b)

Lattice Distortion as a Factor in the Hardening of Metals. W. L. FINK & K. R. VAN HORN. *Engineer*, Vol. 150, Sept. 19, 1930, page 319.
Abstract of paper read before the Institute of Metals, Sept. 10, 1930. See *Metals & Alloys*, Vol. 1, Nov. 1930, page 845. LFM(5b)

Photo-Ionization of Caesium Vapor by Absorption between the Series Lines. C. BOECKNER & F. L. MOHLER. *Bureau of Standards Journal of Research*, Vol. 5, Oct. 1930, pages 831–842.
Measurements by the space-charge method were made on photo-ionization resulting from a small continuous absorption between series lines. (5b)

Recrystallization of Electrolytic Copper after Hot Rolling. W. TAFEL. *Metals & Alloys*, Vol. 1, Jan. 1930, pages 347–349.
Translation from *Zeitschrift für Metallkunde*, Aug. 1929, page 265–267. See abstract in *Metals & Alloys*, Vol. 1, Jan. 1930, page 340. (5b)

The Technique of Radiography and Gamma Rays. CHARLES S. BARRETT, ROYAL A. GEZELIUS & ROBERT F. MEHL. *Metals & Alloys*, Vol. 1, Dec. 1930, pages 872–879.
Gamma rays can be used in the place of X-rays. The apparatus is simpler and the penetrating power is greater which multiplies the possibility of application. Materials which fluoresce under the action of γ-rays can be made into effective intensifying screens. Calcium tungstate is satisfactory. It is customary to use duplicate films separated by a lead screen. Observations are described which determine the curve of depth in inches of iron plotted against time of exposure. Curves are given for 2 arrangements of screens and one density from a distance of 18". Other screens or densities move the curve along the abscissa. For exposure at d inches the time is multiplied by $d^2/18$. Gamma-ray photographs show less contrast than X-ray photographs. The ratio of the intensity of the unabsorbed rays to that of the rays that have passed through the casting is much greater for X-rays than for γ-rays. Also the angular distribution of the intensity of the scattered rays is a cause of less halation with γ-rays. Data are given regarding these factors which permits calculation of the fogged area under given conditions. ESC(5b)

The Development of Modern X-Ray Generating Apparatus. W. D. Coolidge (General Electric Co.). *General Electric Review*, Vol. 33, Nov. 1930, pages 608–614; Dec. 1930, pages 723–726.

An abstract of a paper delivered as the "Caldwell Lecture" before the American Roentgen Ray Society at West Baden Springs, Sept. 24, 1930. Its purpose was to emphasize some of the fundamental principles involved, so as to show why X-ray generating apparatus has its present limitations and to indicate in a few cases how the capabilities of the apparatus may be increased in the future. Various types of X-ray tubes and the preparation of the metallic tungsten filament are illustrated. WHB(5b)

X-Ray Inspection of Castings. *Journal Society Automotive Engineers*, Vol. 25, Nov. 1929, page 551.

A discussion of the value of X-ray analysis of castings. X-ray inspection is found to be used successfully in the examination of cast steel, bronze and aluminum, as well as in some other cases. (5b)

An Instrument for High Voltage X-Ray Spectrography and Radiography. F. Sillers, Jr. (Follansbee Bros. Co.). *Transactions American Society for Steel Treating*, Vol. 18, Aug. 1930, pages 220–234.

Contains 5 references. The paper describes the author's X-ray outfit using voltages of 200 kv. to take simultaneously 4 X-ray spectrograms, of comparable intensities, from samples of silicon sheet steel. By rotating the X-ray tube 90° on its axis the outfit may be used for radiography. The author discusses the use of this instrument for the inspection of electrical sheet steel of high silicon content. WLC(5b)

Study of the Grain Structure of Martensite. K. Heindlhofer & E. C. Bain (U. S. Steel Corp.). *Transactions American Society for Steel Treating*, Vol. 18, July 1930, pages 70–125.

A paper presented before the semi-annual meeting of the Society in New York, Feb. 7–8, 1930. Includes discussion and 9 references. New data on the crystal structure of martensite obtained by X-ray methods and the use of the petrographic microscope are presented. The authors conclude that the "Unit" or grain size of martensite is not small, as formerly held from the diffuse lines of the X-ray spectrum, but large; and that the diffuse lines are due to a random irregularity of the "solid solution type." A twisting or bending type of distortion between the planes of as much as 4° is noted. The hardness of martensite appears to be largely due to the solid solution irregularity and to a smaller extent to the twisting of the planes. In discussion, Dr. H. H. Lester (Watertown Arsenal) confirms the author's view of the grain size of martensite and the predominance of the solid solution effect. The body of the paper treats in considerable detail the technique involved in careful X-ray measurements and the use of the petrographic microscope in the authors' research. WLC(5b)

Note on the Use of Gamma Rays for Examining Welds. R. F. Mehl (Naval Research Laboratory), G. Doan (Lehigh University), & C. S. Barrett (Naval Research Laboratory). *Journal American Welding Society*, Vol. 9, Sept. 1930, pages 104–106.

Describes method used for examining heavy castings and welds for internal defects. Radium apparatus consists of capsule about size of cartridge containing source of rays. Its small size allows it to be used on top of partly constructed buildings or even under water. Welds can be radiographed in places inaccessible to usual apparatus. The bulb of radium emanation is supported in front of weld with photographic film fastened behind weld. Flaws in weld show up on developed film just so in ordinary X-ray radiographs. Gamma rays have power of penetrating much greater thicknesses than X-rays. It is possible to take radiographs through 1 ft. of steel. High penetrating power causes defects to show up with less contrast than with X-ray but good pictures of irregular thicknesses are easier to obtain. Not expensive method because radium can be rented from hospitals. Gives 2 radiographs of welds showing defects. LFM(5b)

An X-Ray Investigation of the Lead-Antimony Alloys. D. Solomon & W. Morris Jones. *London, Edinburgh & Dublin Philosophical Magazine & Journal of Science*, Vol. 10, Sept. 1930, pages 470–475.

8 references. Crystal structures were examined by the X-ray powder method. Photographs were taken of Sb, Sb 70% and Pb 30%, Sb 20% and Pb 80%, and of Pb. The results are tabulated in 4 tables which show the quality of the copper radiation, a copper target was used in the experiment, second the Miller indices of the reflecting planes, third the intensities of the lines on the photograph, fourth the plane spacings obtained from measurements on the film, and fifth the calculated spacings for the structure found. X-ray analysis does not indicate a solid solution at either the Pb or the Sb end of the diagram. There are no definite compounds in the Pb-Sb system of alloys, and if Pb is soluble in Sb or Sb in Pb the degree of solubility of either metal in the other is very small at room temperature. The work of Dean, Broniewski and Sliwowski is briefly reviewed. This work agrees with that of Dean but not with other 2 who claim formation of a solid solution. RHP(5b)

The Electron Theory of Metals in the Light of the Wave-Mechanical Statistics. (**Zur Elektronentheorie der Metalle nach der wellenmechanischen Statistik.**) A. Sommerfeld. *Zeitschrift Verein deutscher Ingenieure*, Vol. 74, May 10, 1930, pages 585–588.

Many questions regarding physical properties of metals could not find a proper explanation without leading to contradictions in the classical theory. Drude explains a new theory of metals which is based on wave-mechanics and the "Pauli" prohibition and "Fermi" statistics. The former states that each quantum-state can exist only once in the whole system of a metal atom, and according to the Fermi-statistics the electron is not only to be considered as a corpuscle, as in the classical theory, but also as a wave-state. These new ideas have had excellent results as now specific heat, electric-resistance, and the emission of electrons from a metal, even at low temperatures, can be fully explained in conformance with the observed facts. The Pauli-prohibition has found the finest confirmation in the theory of the spectral phenomena and in the structure of the atoms in the periodic system. The electric resistance is proportional to the free length of path, that is, the average length between 2 collisions of an electron with the metal ions, and as the free length is proportional to the absolute temperature, the resistance behaves in this manner. The new theory shows that the old Maxwellian views are right above a certain temperature while below that down to absolute zero the curve of the velocity of electrons assumes a constant value. The average energy of an electron is not dependent on temperature. The double nature of the electron as corpuscle and as wave as now received, has been of eminent consequence in modern physics. Ha(5b)

X-Ray Examination of the Modifications of Manganese. (**Röntgenographische Untersuchungen der Manganmodifikationen.**) Einar Oehman. *Metallwirtschaft*, Vol. 9, Oct. 3, 1930, pages 825–827.

Contains 17 references. Three modifications of pure manganese have been found by X-ray examination. α is stable from ordinary temperature to 742°C., β from 742° to 1191°, and above 1191° C. γ exists. The rate of transformation from one modification to another is retarded by Al and Fe impurities in Mn, therefore, technical Mn is usually a mixture of $\alpha + \beta$, and never contains any γ. The elementary length of α Mn is 8.894 A.U., β 6.300 A.U. The interference lines of α do not coincide with those of β. γ has not yet been obtained by quenching pure Mn from high temperatures. The lattice dimensions of γ can be determined by interpolation from several Mn–Cu alloys. γ exists only in electrolytic Mn. It is face centered tetragonal while α and β are cubical. CEM(5b)

The Industrial Use of X-Ray Interference Methods. (**Die industrielle Anwendung der Röntgen-Interferenzmethoden.**) Alfred Reis. *Metallwirtschaft*, Vol. 9, May 30, 1930, pages 468–470.

A discussion of the advantages of the powder method of X-ray examination, the necessary conditions for its use, description of the process. Use of X-ray examination for control work, for purchased materials and products of manufacture. Micro examination for structure versus macro examination for flaws and defects. CEM(5b)

Lattice Disturbances on Gliding Surfaces, from an X-Ray Examination of Rock-Salt. (**Ueber Gitterstörungen an Gleitflächen, nach einer röntgenographischen Untersuchung aus Steinsalz.**) Wolfgang Berg. *Wissenschaftliche Veröffentlichungen aus den Siemenskonzern*, Vol. 9, No. 2 (1930) pages 119–143.

The different properties of crystals can be divided into two classes: integral properties which bring the whole crystal into action, and differential properties which depend on the quality of the crystal at different places, where consequently the defects of the crystal come into play. To the former belong, thermal conductivity, specific heat, elasticity modulus, properties which are independent of the defects of a crystal while some mechanical properties, tensile and compression strength, ion-conductivity, dielectric-strength are differential properties. To the latter belongs also the fact of the existence of certain preferred gliding surfaces. To explain these properties the defects have to be taken into account. The author develops an apparatus for obtaining a photograph by a simple reflection of a limited X-ray beam on a crystal. For rock-salt this picture shows regularly arranged light and darker stripes. The behavior of the stripes under different test conditions permits a conclusion as to the kind of deformation of the lattice at the gliding surface. The observation of the strips offers a very sensitive method for the determination of gliding surfaces and gliding directions in mono-crystals; the same good results can be expected also in metal crystals. Ha(5b)

The X-Ray Examination of Atomic Structure. (**Die Untersuchung der Atomenordnung mittels Röntgenstrahlen.**) W. Lawrence Bragg. *Metallwirtschaft*, Vol. 9, May 30, 1930, pages 461–465.

Contains 6 references. A review. The principle of X-ray examination is the same as microscopic examination, waves are used to illustrate structure. In micro examination a picture results, in X-ray study calculations are necessary to obtain results. Examples are given. X-rays should be regarded as a new source of illumination for microscopy, not as a new science. The relative position of atoms can be studied with X-rays. CEM(5b)

The Structure of the Spectrum of Singly Ionized Zirconium. C. C. Kiess & Harriet K. Kiess. *Bureau of Standards Journal of Research*, Vol. 5, Dec. 1930, pages 1205–1239.

Seventy-five percent of the lines observed in the spark spectrum of zirconium have been classified as combinations between terms of the quartet and doublet systems of Zr II. The terms which have been found are in all cases those required theoretically for an atom with three outer electrons. All the terms, except one, which can possibly arise from configurations of the electrons when they occupy 4d, 6s and 5p orbits have been found. Of the terms possible when one of the electrons removes to a 5d or 6s orbit only a few have been found, of which some form Rydberg series with the low terms. In all, 10 pairs of series-forming terms have been detected with either ^3F, ^1G, or ^1D of Zr III as limit. The results given by these different series for the distance between a $^4F_{1\,1/2}$, the lowest term of Zr II, and a^3F_2, the lowest term of Zr III, are very consistent, the mean value being 113, 175 cm^{-1}, corresponding to an ionization potential of 13.97 volts for the ion Zr^+. The irregular doublet law shows a close parallelism between the term structures of the neutral Yt atom and the singly ionized Zr atom. The list of Zr II lines appearing in the sun is extended and includes lines which have not been observed in laboratory sources but may be calculated from permissible combinations. (5b)

The Soft X-Rays of Manganese. F. C. Chalklin. *London, Edinburgh & Dublin Philosophical Magazine & Journal of Science*, Vol. 9, May 1930, pages 847–857.

Previous experiments have shown that for each of the elements iron, cobalt, nickel and copper there exists in the soft X-ray region, a considerable number of critical potentials. To account for these Prof. O. W. Richardson and the author have suggested a scheme involving the assumption that the critical potentials are due to transitions from a number of initial levels to a Rydberg series of virtual levels. The present experiment determines the critical potentials of manganese by 2 distinct variations of the photo-electric method. Discusses the apparatus and methods of procedure, and the results obtained from each method. The critical potential scheme advanced by Richardson and Chalklin does not account for the discontinuities found for manganese above 280 volts, and for iron, nickel, cobalt and copper there are unpredicted effects in this region. If the scheme is to be comprehensive it will require extension but the data available at present does not justify such extension. RHP(5b)

Measurement of Lattice Derangements with X-Rays. (**Messung von Gitterstöhrungen mit Röntgenstrahlen.**) J. Hengstenberg. *Metallwirtschaft*, Vol. 9, May 30, 1930, pages 465–468.

Gives 8 references. An X-ray study was made of annealed and rolled metals. The effect of strengthening a metal by working, alloying and heat treating on the lattice change is discussed, the influence of lattice change on the intensity of X-ray reflections and the results of intensity measurements are given. Single crystals are examined. CEM(5b)

An X-Ray Investigation of the Copper-Magnesium Alloys. Geoffrey Grime & W. Morris-Jones (University College, Swansea). *London, Edinburgh & Dublin Philosophical Magazine & Journal of Science*, Vol. 7, June 1929, pages 1113–1134.

Eight alloys were examined by the X-ray powder method. Their compositions were determined by an electrolytic method and their densities by the suspension method. The equilibrium diagram of Sahmen was confirmed in its main features. Two new regions of solid solution were detected; 1. The α-phase–as solution of magnesium in the copper lattice up to approximately 3% magnesium. 2. The β-phase–a range of solution extending on either side of the composition represented by the formula Cu_2Mg. This range is estimated to be confined to 2 or 3% on either side of the Cu_2Mg solid solution could not be detected at the maximum end of the diagram. The lattice constants of copper and magnesium were determined. RHP(5b)

PHYSICAL, MECHANICAL & MAGNETIC TESTING (6)

Inspecting Bar Stock by Magnetic Analysis. R. R. Moore (Wright Aeronautical Corp.). *Machinery*, Vol. 36, May 1930, pages 672–673.

Abstract of an article appearing in *The Tradewind*. See *Metals & Alloys*, Vol. 1, July 1930, page 629. RHP(6)

An Investigation of the Phenomena of Strengthening of Steel and Its Behavior under Repeated Overstresses. A. Thum & W. J. Wiss. *Transactions American Society for Steel Treating*, Vol. 18, July 1930, pages 49–54.

The paper is a summary of a thesis for Dr. Ing. degree at Technical University of Darmstadt, Germany. The effect of previous stressing on the endurance properties are discussed. By gradually increasing the load on a specimen during an endurance test its endurance limit may be increased about 20%. See *Metals & Alloys*, Vol. 1, Dec. 1930, page 908. WLC(6)

Method and Apparatus for Determination of Ductility and Tensile Strength of Sheet Metals. (Methode et apparail d'essai donnant le coefficient d'extension et la charge de rupture des produits metallurgiques en feuilles.) CH. JOVIGNOT. *Revue de Metallurgie*, Vol. 27, Aug. 1930, pages 443–448.

Inaccuracies of reading in Erichsen type of ductility testers are caused largely by friction of the ball and lack of sharpness in the determination of the end point. In the present apparatus, the ball is replaced by hydraulic pressure applied directly to the sheet held in a die of practically standard design. The apparatus entirely eliminates the drawbacks of friction, sharply defines the end point, gives a direct reading of the depth of the cup, always gives comparable results, indicates the homogeneity of the sample and its readings can be easily extrapolated into figures of tensile strength. Description of the apparatus and conversion graphs into tensile strength are given. JDG(6)

Young's Modulus Determined with Small Stresses. D. K. FROMAN. *Physical Review*, Vol. 35, Feb. 1, 1930, pages 264–268.

A report from Ryerson Physical Laboratory of the University of Chicago on the interferometer method of determining extensions of metallic rods of brass, steel, Cu, Al, and Ni under stresses considerably less than those used in commercial testing. Young's modulus was found to increase very rapidly as stress increased from zero, reach the maximum at comparatively small stress, and then to decrease almost exponentially to ordinary value. (6)

Atmospheric Action in Relation to Fatigue in Lead. BERNARD P. HAIGH & BRINLEY JONES. *Journal of the Institute of Metals*, Vol. 43 (1930) pages 271–295.

Includes discussion. See *Metals & Alloys*, Vol. 1, Oct. 1930, page 795. (6)

The Physical Properties of Basic Bessemer and Open Hearth Steels. (Die mechanischen Eigenschaften von Thomas und Siemens Martin Stählen.) K. DAEVES. *Stahl und Eisen*, Vol. 50, Sept. 25, 1930, pages 1353–1356.

It was found by evaluating a very large number of tests on the physical properties of Thomas and open hearth steels that the Thomas steel has a higher elongation and reduction of area than open hearth steel, of same tensile strength. In evaluating the results of rail steels with from 36–100 kg./mm.^{2} tensile strength for instance, the elongation of the Thomas steels was 2% and the reduction of area 4% higher than for open hearth steels. No reliable information can be given yet as to the metallurgical causes of the difference of physical properties. GN(6)

The Fatigue of Metals. *Machinery* (London), Vol. 36, June 12, 1930, pages 335–338.

A discussion of accelerated fatigue tests and the relation between endurance limit and physical properties. The mechanism of fatigue, corrosion fatigue, stress-cycle curves and notch effects are also considered. (6)

Large Material Testing Machines. (Grossprüfmaschinen.) *Zeitschrift Verein deutscher Ingenieure*, Vol. 74, Oct. 4, 1930, page 1399.

Short description of a 100-ton compression testing machine built by Maschinenfabrik Augsburg-Nürnberg. Accuracy of ±1% is guaranteed. Ha(6)

Suggested Methods of Reporting on Nitrided Steel Case. GEORGE M. EATON. *Transactions American Society for Steel Treating*, Vol. 17, June 1930, pages 765–783.

Paper presented before the Semi-annual meeting of the Society in New York, Feb. 7–8, 1930. In the body of the paper, the author suggests the need for uniform methods of reporting nitrided case characteristics, the use of a logarithmic scale of hardness and a plain scale of depth, and a merit factor for wear. Appendices cover the possibilities of the scleroscope for inspection, wear testing, straightening vs. case ductility, and hardness vs. wear resistance. WLC(6)

Strength of Welded Shelf-Angle Connections. JAMES H. EDWARDS, H. L. WHITTEMORE & A. H. STANG. *Bureau of Standards Journal of Research*, Vol. 5, Oct. 1930, pages 781–792.

The specimens were tested to destruction in the 10,000,000-pound testing machine of the National Bureau of Standards. (6)

Transverse Tests of H-Section Column Splices. JAMES H. EDWARDS (American Bridge Company), H. L. WHITTEMORE (Bureau of Standards) & A. H. STANG (Bureau of Standards). *Journal American Welding Society*, Vol. 9, June 1930, pages 7–28.

Reprinted from *Bureau of Standards Journal of Research*, Vol. 4, March 1930. See *Metals & Alloys*, Vol. 1, July 1930, page 629. LFM(6)

Stress Distribution in Welded Steel Pedestals. JAMES H. EDWARDS, H. L. WHITTEMORE & A. H. STANG. *Bureau of Standards Journal of Research*, Vol. 5, Oct. 1930, pages 803–811.

Two welded steel pedestals were tested in compression and a study of the stress distribution was made. (6)

The Damping of Materials at Alternating Normal Stresses and at Alternating Compression Stresses. (Die Dämpfung der Werkstoffe bei wechselnden Normalspannungen und bei wechselnden Schubspannungen.) O. FOEPPL. *Zeitschrift Verein deutscher Ingenieure*, Vol. 74, Oct. 4, 1930, pages 1391–1394.

The conceptions of damping ϑ and relative damping ψ are explained and the importance of these quantities for the determination of quality of a material is pointed out. The magnitude of damping can be determined at alternating stresses for one element. The damping has been measured on the one side as a function of the normal stress, and on the other as a function of the compression stress. The two curves almost coincide for most of the examined materials if the damping occurring at normal stresses is plotted as a function of the compression stress occurring at 45° to the direction of main stress. The curves for steel, copper, and brass show only very little difference while those for Electron show, however, a much larger, unexplainable difference between torsion and bending. 11 references. Engine Parts and Metallurgy. (Maschinenteile und Werkstoffkunde.) E. HEIDEBROCK. *Zeitschrift Verein deutscher Ingenieure*, Vol. 74, Sept. 13, 1930, pages 1259–1265.

In the meeting of the committee on machine elements, the influence of experience and research in metallurgy on design was discussed which is reviewed in the paper. The following questions were discussed: the present-day state of metallurgy and its influence on the shape of rigid joints, fatigue tests, strength calculations, shaping of large forgings, parts for high-pressure hot-steam, high speed reciprocating engines, belts, slide-couplings, friction coefficients in bearings at low velocities. The paper can not very well be abstracted in short, it is illustrated by many figures and tables and 14 references. Ha(6)

Hardness by "Cloudburst." EDWARD G. HERBERT. *American Machinist*, Vol. 72, June 5, 1930, pages 917–920.

In the cloudburst a shower of hard steel balls is allowed to fall on the work from a predetermined height. 750,000 steel balls of about 3 mm. are dropped per minute. It tests the whole surface of the work. The parts of less than the specified hardness are identated. Internal surfaces may be tested by use of a deflector. This method will also detect brittleness. See *Metals & Alloys*, Vol. 1, Sept. 1929, page 121. RHP(6)

Stress Strain Relationships in Spring Steels. G. A. HANKINS. *Engineer*, Vol. 150, Aug. 15, 1930, pages 178–179. 7 references.

Communication from the Spring Committee of the Department of Scientific and Industrial Research. Short general discussion of stress-strain relationships in spring steels under conditions which are often assumed to be elastic. Gives experimental results on changes in elastic moduli after excessive over-straining of the material. LFM(6)

The Effects of Two Years' Atmospheric Exposure on Breaking Load of Hard-Drawn Non-Ferrous Wires. J. C. HUDSON. *Engineer*, Vol. 150, Sept. 26, 1930, page 335; *Engineering*, Vol. 130, Oct. 17, 1930, pages 507–508.

Abstract of paper read before the Institute of Metals, Sept. 11, 1930. See *Metals & Alloys*, Vol. 1, Dec. 1930, page 909. LFM(6)

Creep Limit under Alternating Tension and Compression. (Der Fliessbeginn bei wechselnder Zug-Druckbeanspruchung.) W. KUNTZE & G. SACHS. *Metallwirtschaft*, Vol. 9, Jan. 24, 1930, pages 85–891.

Contains 3 references. Stress-strain diagrams of metals were determined on cylindrical test pieces, using an alternating tensile and compressive load, which was gradually increased. The difference between the first and subsequent curves is called Bauschinger effect. The Bauschiner effect starts suddenly at a point independent of the conventional elastic limit and yield point and its relation to the elastic limit is different for different materials. It is called the alternating elastic limit. With cold worked metals this limit is lowered at the second reversal in load with low load amplitude and then reappears at the typical point for that metal. CEM(6)

Determination of the Hot Yield Point of Steel. (Zur Bestimmung der Warmstreckgrenze von Stahl.) F. KÖRBER & A. POMP. *Mitteilungen Kaiser Wilhelm Institut für Eisenforschung*, Vol. 12, Report No. 155 (1930) pages 165–169; *Stahl und Eisen*, Vol. 50, Oct. 9, 1930, pages 1443–1444.

The investigation determined the hot yield point of an open hearth steel of the following composition: 0.046% C, 0.18% Si, 0.33% Mn, 0.020% P and 0.028% S by studying (1) the influence of the time during which the load is applied on the value of the hot yield point, (2) the influence of the number of the load steps on the value of the hot yield point and (3) the influence of the time which passes after the removal of the load applied on the value of the hot yield point. The load which is necessary for obtaining a permanent elongation of 0.2% of the test length of a bar is defined as hot yield point. The velocity of the load increase amounted to 0.5 kg./mm.^{2} per second. The load was kept constant at the various load steps (3 to 6) for the following times: 10, 30, 60, 300, 600 and 1800 seconds. The temperatures used were; 300°, 400°, 450°, 500°, 550° and 600° C. The results are: (1) A lowering of the hot yield point occurs at all temperatures with increasing load time. The slope of the curves is most pronounced within the time range between 10 and 300 seconds. In increasing the time during which the load is applied above 300 seconds no essential further decrease of the hot yield point is observed. Comparing the values of the hot yield point for 10 and 1800 seconds, a decrease of 13.6% was found at 300°, 11.3% at 400°, 22.8% at 450°, 37.5% at 500°, 28.0% at 550° and 34.3% at 600° C. These observations, which point out the large influence of the factor at issue on the determination of the hot yield point, explain the discrepancies in the literature referring to this subject. (2) The influence of the number of load steps was studied at 300° and 500° C. The number of the load steps amounted from 2 to 4 and from 12 to 15, respectively. The load time amounted to 10 and 500 seconds, respectively. It results that the number of the load steps is practically without influence on the value of the hot yield point. (3) The waiting time after removing load applied has no bearing on hot yield point. GN(6)

Present-Day Experimental Knowledge and Theories of Fatigue Phenomena in Metals. Report of Research Committee on Fatigue of Metals. H. F. MOORE, Chairman. *Preprint for* Vol. 30, Part I, 1930. *Proceedings American Society for Testing Materials*, 52 pages. 117 references.

The status of present knowledge on the determination of endurance limit, types of machines and of specimens, accelerated tests, correlation of endurance limits with other physical properties, effect of range of stress and kind of stress, metallographic features, fracture under repeated stress, mechanical hysteresis, detection of incipient fatigue failures, effect of alloying and heat-treatment, overstressing, understressing, cold working, stress concentration, corrosion-fatigue, and the significance of fatigue test results, are discussed by H. F. Moore, R. R. Moore, J. R. Townsend, J. B. Kommers, H. S. Rawdon, R. L. Templin, H. W. Gillett, T. McLean Jasper and R. E. Peterson. While individual views are given on each topic, the various sections have been checked over by the whole committee. The result is a very concise summary of available information on endurance of metals, but too concise to be effectively abstracted. Professor Moore's closure on significance of fatigue testing is especially important as it emphasizes the fact that fatigue failure is only one of various modes of failure of metals, and that if the life depends on some other factor than the effect of repeated stress, fatigue testing cannot be expected properly to evaluate the usefulness of the metal for such service. HWG(6)

Magnetic Welding of Butt Welds. T. R. WATTS (Westinghouse Elec. & Mfg. Co.). *Journal American Welding Society*, Sept. 1930, Vol. 9, pages 49–68. 6 references.

For magnetographic inspection of welds, the electromagnet used for getting flux through welded structure is placed on under side of the welded plate bridging the weld. Very fine iron powder is sifted upon piece of paper laid on weld. Cracks, blow-holes, poor fusion or similar faults offer higher magnet resistance to the flux, and are indicated by dense collection of fine iron particles directly over fault. A more quantitative weld test is measurement of magnetic potential drop across the weld and for the same distance in the parent metal. Same flux goes through weld and adjacent parent metal hence magnetic potential drop between any 2 points is proportional to reluctance between those 2 points, indicating quality of the weld. Describes simple type of weld test meter which is small and rugged. Results are easily and quickly interpreted by reference to calibration curves. Investigations indicate that magnetic test methods detect serious faults and give more accurate measure of weld quality than other known methods practicable for shop use. LFM(6)

Yield Point of Structural Steel (Report of Research Committee on). M. O. WITHEY, Chairman, *Preprint for* Vol. 30, Part I (1930). *Proceedings American Society for Testing Materials*, 26 pages.

In a coöperative study, the yield point of specimens cut from structural shapes of 16 different sizes and shapes, ranging from $^3/_8$" plate to 26" girder beam and made from steel of 0.14 to 0.29% C, 0.37 to 0.73% Mn, was found to range from 29,000 to 39,000 lbs./in.^{2} depending on variations in rolling and cooling conditions, on finishing temperature, on size of section and position of the specimen in the section. The ratio of yield point by drop of beam to tensile strength ranged from 0.50 to 0.65, hence it cannot be estimated with sufficient accuracy from the tensile values. There was considerable discrepancy between mill tests and the more carefully conducted coöperative tests. A single specimen will not adequately represent the average properties of heavy girder beams and H-column shapes and 3 specimens from intermediate flange, root and web should be taken. If only one is taken, it should come from the intermediate flange. The most representative single specimen is from an intermediate location in plates and angles and from the center of the web in channels and I-beams. HWG(6)

The Notch Toughness of a Few Aluminum Alloys Especially at Low Temperatures. (Ueber die Kerbzähigkeit einiger Aluminium legierungen insbesondere bei tiefen Temperaturen.) W. A. GÜLDNER. *Zeitschrift für Metallkunde*, Vol. 22, Aug. 1930, pages 257–260.

The alloys studied were: Lautal (4.62 Cu, 0.45 Fe, 0.29 Mg, 0.56 Mn, 0.74 Si) of which in one series the rolled alloy was heated to 500° and water quenched, and in another series heated to 500° quenched in water and annealed at 120–130°; Duralumin (3.95 Cu, 0.5 Fe, 0.05 Mg, 0.56 Mn, 0.12 Si); "German alloy," sand and die cast, (2.4 Cu, 11.22 Zn, 0.59 Fe, 0.14 Si); "American alloy," sand and die cast, (8.75 Cu and 0.47 Fe). Especial attention was given to the effect of the velocity of test from zero (static test) upward. The notch impact values were found to depend upon this velocity, increasing linearly with velocity except for the static values which were low. The percentage increase is characteristic of the property of the material tested. It changes with previous mechanical treatments but not with thermal. The static values are less than the dynamic and show no considerable influence of mechanical or thermal treatment. The notch impact value was found to be independent of the weight of the hammer; it increases with increased weight of the hammer only when this increased weight induces an increased velocity. The notch impact values of the Al alloys were found to be very small. The work is being continued. (6)

The Resistance of Steels to Abrasion by Sand. SAMUEL J. ROSENBERG. *Bureau of Standards Journal of Research*, Vol. 5, September 1930, page 553–574.

A study has been made of the adaptability of 3 types of apparatus, namely, the ball-mill, the sand blast and the Brinell machine, to the testing of the resistance of metals to abrasion. A detailed description of all apparatus used is given. The ball-mill was generally unsatisfactory; the sand blast gave consistent results but did not differentiate between the materials tested, apparently because of the fact that the abrading conditions were not sufficiently severe; but the Brinell machine proved to be generally satisfactory. The Brinell test showed that the resistance to wear of normalized, annealed, hardened or tempered carbon steels increases with their hardness. Increasing the temperature of annealing resulted in a slight increase in resistance to wear, the increase being more marked in a low-C than in a high-C steel. Abrasion in this type of test is caused by the gradual breaking up of the individual grains and not by the removal of separate grains in their entirety and this action is accompanied by local strain hardening. (6)

The Testing of Sheet Metal. *Metallurgist*, Sept. 1930, pages 139–141.

The testing of sheet metal by the ordinary tensile test is very difficult due to the tendency to tear rather than to produce a true tensile rupture. Ductility which is especially important in sheet materials is generally determined by bending tests which are open to the objection that either the piece is subjected to tensile stress at the time of bending or the repeated bendings do not take place at the same place. The cupping test which has been devised to overcome these difficulties is itself open to objection because of the large amount of friction between the plunger and the sheet introducing complicating features and the fact that, since the point of cracking is determined by visual inspection, an expert operator is required. Machines replacing the plunger by liquid have, therefore, been devised. These attempt to eliminate the friction between plunger and sample and the indication of failure is given by the escape of liquid and a sudden fall in pressure. Such a machine reported by Ch. Jovignot in the August number of the *Revue de Metallurgie* is described. The details of the machine as given are inadequate.

On the Influence of Small Deformations on the Physical Properties of Chains and Chain Materials. (Ueber den Einfluss geringer Verformungsgrade auf die Festigkeitseigenschaften von Ketten und Kettenbaustoffen.) W. PÜNGEL. *Stahl und Eisen*, Vol. 50, Sept. 11, 1930, pages 1297–1301.

Contains 3 references. Report of the Research Institute of the Vereinigten Stahlwerke, Dortmund, Germany. The results of an investigation on the influence of small deformation of chain steels on its sensibility for aging are as follows: A premanent deformation of 2–4% of the length of a chain link occurs when wrought iron chains as well as steel chains are stretched at 12 kg./mm.², according to the normal test procedure. This permanent deformation is due to the unfavorable section modulus in the bend of the chain link for bending stresses. The sensibility for aging is essentially increased for basic steel after small deformations from 1–4%. This holds for both the stretched and tempered (aged) state of the materials. Annealing is necessary. Annealing temperatures of 950–1000° C. are most suitable. An annealing at 700° C. tends to show up recrystallization even for these small deformations. Annealing at 1100° C. endangers the materials due to burning. Chains should always be annealed after the performance of the prescribed stretch test. Since the actual stresses of 5–7 kg./mm.² during the use of chains lead to permanent deformations, aging and brittleness occur after a certain time of use. It is advisable, therefore, to anneal used chains once a year at 900° C. Recommendations are furthermore made as to the development of more favorable shapes of chain links. GN(6)

The Testing of Materials in France. *Metallurgist*, June 1930, pages 84–85.

A critical review of a paper by M. P. Nicolau on "Some Recent Advances in Methods of Controlling Metallurgical Products" appearing in the Feb. issue of the *Bulletin de la Société d'Encouragement pour l'Industrie Nationale* which is interesting because of its comparison of French thought with that of other countries. Apparently the French are entirely oblivious of work accomplished or conclusions obtained in any country except their own. The entire question of fatigue and corrosion fatigue is completely ignored and cases that are evidently those of true fatigue failure are ascribed to "fissuration" initiated either by a pre-existing crack or flaw or brought about by failure of the material to stand shock. Other cases are cited and the need of dissemination of American, British and German work into French thought to the mutual advantage of both is emphasized. VVK(6)

Cold Working and Young's Modulus. *Metallurgist*, Aug. 1930, pages 115–116.

Some recent work on Young's modulus by Mr. Tadashi Kawai in *Science Reports of the Tokohu Imperial University, Japan*, Series I., Vol. 19, no. 2 is abstracted somewhat in detail. See *Metals & Alloys*, Vol. 1, Nov. 1930, page 847. VVK(6)

Fatigue and Impact Tests for Welds. CHAS. H. JENNINGS (Westinghouse Electric & Mfg. Co.). *Journal American Welding Society*, Vol. 9, Sept. 1930, pages 90–104. 13 references.

Reviews results obtained by various investigators on fatigue test for butt and fillet welds and impact tests of welds. Tests made by author were confined to arc welds and deposited arc weld metal. Annealing temperatures up to 1550°F. do not appreciably affect the impact strength of the welds. For annealing temperatures of 1550° and 1700° F. the impact strength is greatly reduced. These tests definitely show change in properties of the material that would not be shown by ordinary static tensile tests. Stresses need for tentative standard for dynamic tests, particularly fatigue tests because of extensive use of welds in dynamic structures. Gives tables, diagrams and photographs. LFM(6)

New Fatigue Machines with Swinging Test Bar. (Neuere Dauerbiegemaschinen mit schwingendem Probestab.) G. V. HEYDEKAMPF. *Metallwirtschaft*, Vol. 9, April 11, 1930, pages 321–326.

Contains 10 references. A new fatigue testing machine using a swinging test bar with either fixed or variable load is described, as distinct from the usual type with rotating test bar and constant load. It duplicates the action of automobile springs and airplane parts. Details of the apparatus and test bar are given. CEM(6)

Destructive and Non-Destructive Tests of Welds. A. B. KINZEL & J. K. DAWSON (Union Carbide & Carbon Res. Lab., Inc.). *Mining & Metallurgy*, Vol. 11, June 1930, pages 308–313.

Describes the various destructive and non-destructive tests that are in use and methods of carrying them out. Tensile testing of welds consists of producing failure in the specimen by applying a measured load. The latest bend test developed is known as the quantitative free bend test. The performance of the material in bending is measured by the amount of stretch in the outer fibers at the instant of failure. Fatigue and Izod tests are rarely applied in routine testing of welds. Another test used in research but not suitable for routine application consists of a hardness exploration of weld and adjacent base metal. Usually carried out with a Rockwell cone tester. The first non-destructive test applied to welds was the hydrostatic test. X-ray and stethoscopic testing are the most practical for non-destructive testing. See *Metals & Alloys*, Vol. 1, March 1930, page 427. VSP(6)

The Influence of Cross-Sectional Holes on the Endurance Limit. (Der Einfluss von Querbohrungen auf die Biegungsschwingungsfestigkeit.) HILMAR DÖRING. *Metallwirtschaft*, Vol. 9, Sept. 19, 1930, pages 781–786.

Contains 5 references. Holes 7.2 mm. diam. drilled transversely through bars 24 mm. diam. lower the endurance limit from 59 to 72%. 2 or 4 holes were drilled through the test pieces at various distances from the middle. Punched holes are slightly better than drilled holes, but the formation of ridges must be avoided. Grinding the holes is no improvement on account of the danger of cracking. CEM(6)

Progress in the Theory of Ferro-magnetism. (Fortschritte in der Theorie des Ferromagnetismus.) W. HEISENBERG. *Metallwirtschaft*, Vol. 9, Oct. 10, 1930, pages 843–844.

A review and discussion of 9 references covering the progress during the last 15 years. CEM(6)

Tensile Properties of Rail and Other Steels of Elevated Temperatures. J. R. FREEMAN & G. W. QUICK. Condensed by Richard Rimbach. *Metals & Alloys*, June 1930, pages 556–558; *Iron & Coal Trades Review*, Vol. 120, June 13, 1930, pages 947–948.

An extended abstract. Special study was made of rail steels and some other steels in the approximate temperature range of 400–700° C. It is shown that ductility decreases with increase in temperature over a portion of this range. This range is termed the "secondary brittle" range to distinguish it from the "blue brittle" range occurring at 200–300° C and the "hot short" range which is usually associated with the A_3 transformation and high sulphur content. The degree of secondary brittleness varies markedly between individual heats and the temperature of maximum effect also varies. It is shown that this phenomenon is not confined to individual rails or ingots but apparently is a property of the heat as a whole. The cause of the phenomena has not been determined. A hypothesis as to the formation of shatter cracks in rails, based on the phenomenon of secondary brittleness and temperature distribution during cooling, is presented. See *Metals & Alloys*, Vol. 1, June 1930, page 565. ESC + RHP(6)

Bending Tests of Metal Monocoque Fuselage Construction. R. W. MOSSMAN & R. G. ROBINSON. *N.A.C.A. Technical Note* No. 357, Nov. 1930, 40 pages.

The monocoque fuselage is a thin shell with a modified elliptical section. It may be designed with or without a reinforced skin. Airplane designers are seriously studying this type of construction as it has very good aerodynamic properties. The stresses in the skin for various materials have not been determined except for special designs. The authors proposed to develop a rational formula for non-reinforced structures and tested 3 cylinders 36″ in length bv 36″ in diameter and a wall thickness of 0.014″, 0.022″ and 0.032″, respectively. The cylinders were made of heat treated duralumin. There was no longitudinal reinforcement. There was one flanged U ring at the middle and an angle riveted at each end to give lateral support. The cylinders were supported, for testing, at one end by bolting through the angle to a backboard. They were loaded as cantilevers and failed by buckling on the compression side. The stresses calculated from the standard beam formula $p = \frac{Mc}{I}$ were 2150, 3890 and 5570 lbs./in.² for the wall thicknesses of 0.014″, 0.022″ and 0.032″, respectively. The authors also calculated the stresses by using a modification of Bazier's formula which gives the allowable stress in terms of the ratio $\frac{\text{Diameter of Cylinder.}}{\text{Wall Thickness}}$. This formula is maximum stress $= \frac{6600000}{D/t}$. These values were 2567, 4034 and 5867 lbs./in.², respectively for the 3 cylinders. The authors are in favor of adopting the latter formula for design as they believe it to be more applicable to structures which are unstable elastically.

These tests must be considered preliminary to more extensive investigations as the maximum stresses can be greatly increased by the use of longitudinal stiffeners without a proportionate increase in weight, and their effect must be determined empirically. JBJ(6)

Metal Covering of Airplanes. J. MATHAR. *N.A.C.A. Technical Memorandum* No. 592, Nov. 1930, 20 pages.

Mathar's article (original in Jahrbuch 1929 der Wissenschaftlichen Gesellschaft für Luftfahrt) is a very brief résumé of a series of experiments on the effect of shear loading on thin plate (0.008″ thickness) with a relatively large ratio of $\frac{\text{Length}}{\text{Height}}$ and with and without stiffeners. The Memorandum contains a theoretical discussion by Prof. H. Wagner on the relationship between stresses and deformation on buckled plate with variations in the spacing of the stiffeners. The paper is limited in scope and it is doubtful if the data could be applied to a practical design problem. JBJ(6)

ELECTRO-CHEMISTRY (7)

Electroplating (7a)

The Plating of Rolled Zinc and Zinc Base Die Castings. E. A. ANDERSON & C. E. REINHARD. *Metal Industry* (London), Vol. 37, July 25, 1930, pages 85–86, 88; Aug. 1, 1930, page 110; *Brass World*, Vol. 26, Feb. 1930, pages 39–41.

Lays stress on certain modifications of well known practice which simplify the production of plated coatings of Zn and emphasize the importance of cleaning. Gives formulae for Ni, Ag, Cd, etc. plating. The out-door exposure test is probably the only valid test of endurance of plated coating in service. VSP(7a)

The Cavity Scale for Measuring Throwing Power. L. C. PAN. *Metal Industry* (N. Y.), Vol. 28, June 1930, pages 271–274.

The cavity scale takes into consideration the electro-magnetic effect, gas film interference, cathode polarization, solution resistance and primary current distribution ratio. Applicable to all types of plating solutions. The scale is made from a metal bar with cavities of various depth representing recesses in articles commonly handled in plating shop. Gives mode of operation and its advantages. Includes historical review of throwing power measurement. VSP(7a)

Protective Value of Some Electrodeposited Coatings. L. DAVIES & A. WRIGHT. *Journal Institute of Metals*, Vol. 43 (1930), pages 247–269.

Includes discussion. See *Metals & Alloys*, Vol. 1, Oct. 1930, page 797. (7a)

Practical Difficulties Associated with Electrodeposition of Chromium. J. W. CUTHBERTSON. *Metallurgia*, Vol. 2, Oct. 1930, pages 208–209; *Metal Industry* (London), Vol. 37, Oct. 31, 1930, pages 421–423; *Chemical Trade Journal*, Vol. 87, Oct. 17, 1930, pages 371–372; *Chemical Age*, Vol. 23, Nov. 1, 1930, *Metallurgical Section*, pages 25–26; *Brass World*, Vol. 26, Dec. 1930, pages 325-326.

Directions for avoiding some difficulties frequently encountered. Contains 2 references. JLG + WHB(7a)

Throwing Power in Chromium Plating. H. L. FARBER. *Metal Industry* (London), Vol. 36, April 4, 1930, pages 389–390.

A summary of report on the research at the Bureau of Standards. See *Metals & Alloys*, Vol. 1, April 1930, page 474. VSP(7a)

Chromium Plating. E. J. DOBBS. *Metal Industry* (London), Vol. 36, April 18, 1930, pages 435–436; *Heat Treating & Forging*, Vol. 16, Aug. 1930, pages 995–997, 999.

Paper read before Sheffield Trades Technical Societies, April 4, 1930. Present Cr solutions are made up from H_2CrO_4, together with certain conducting salts. For bright deposits H_2SO_4 is usually added. Pb anodes are used. Recommends a thick coating of Ni with a thin coat of Cr. Thickness of Ni sub-coating depends on nature of base metal. Adherence of plating. Anodes and vats are considered. VSP(7a)

Electroplating Research Progress. *Metal Industry* (N. Y.), Vol. 28, May 1930, pages 230–231.

A report of the Electroplating Conference held at Rochester, N. Y., March 22, 1930 under the auspices of American Electroplaters' Society and U. S. Bureau of Standards. First session was devoted to industrial plating of automobile and aircraft parts, hardware and silverware. The second session was devoted to reports from research laboratories. The third session to research fund and plans. VSP(7a)

Determination of the Thickness of Chromium Plate. *Metal Industry* (London), Vol. 36, June 6, 1930, page 604.

The General Testing Laboratories, Inc., Detroit devised a method whereby thickness of Cr deposits may be determined. Describes test briefly. VSP(7a)

Nickel Plating for Mass Production. *Brass World*, Vol. 26, Oct. 1930, pages 261–263.

An abstract of a paper read before the Electroplaters' and Depositors' Technical Society by N. R. Laban. The work was roughly classified as low-current density—up to 25 amps./ft.^{2}; medium, 25–50 amps./ft.^{2}; and high—above 50 amps./ft.^{2} High current density affords a more satisfactory deposit as regards mechanical properties as well as greater output. Advantages and disadvantages of the anodic cleaner and the importance of efficient swilling and draining are pointed out. WHB(7a)

Chrome Plating. *Industrial Chemist*, Vol. 6, May 1930, page 193.

A brief note on the dangers involved in chrome plating with suggested precautions. MPB(7a)

The Electrodeposition of Zinc on Aluminum and Its Alloys. H. C. COCKS. *Metal Industry* (London), Vol. 36, April 4, 1930, pages 385–386, 388.

Condensed from a paper read before the Electroplaters' and Depositors' Technical Society, Mar. 26, 1930. Based on results of investigations on the influence of a number of addition agents on the cathode potential and on nature of deposit. Deposits which afforded a good protection from corrosion to Al and Al alloys were obtained from $ZnSO_4$ and $Zn(CN)_2$ baths. Preparation of metal for plating. Result obtained with $ZnSO_4$ solution at pH value within range of 3.0 to 6.0 showed that in general, best results can be had when pH of solution is 4.0. By using moving cathodes a higher current density can be used without freeing of deposits and it tends to sweep off adhering bubbles of air or H and thus diminish formation of gas-pits. Experiments showed that satisfactory deposits of Zn on Al can be obtained from several solutions. All deposits from sulphate baths gave good protection for Al alloys but ammoniacal Zn $(CN)_2$ baths have not. Gum arabic in sulphate baths is recommended. VSP(7a)

New Methods of Electroplating. (Neue Methoden in der Galvanotechnik.) W. PFANHAUSER. *Metallwirtschaft*, Vol. 9, June 13, 1930, pages 506–508.

A review of the progress during the last few years. Better results are now obtained with shorter plating time, for instance in Cu and Ni plating, and with more concentrated electrolytes. The use of higher cathode current densities, agitation of the solution, smaller baths, relation of anode to cathode surface and the use of colorimeters for quick analysis are discussed. The advent of Cd and Cr plating, salt spray test, cleaning of metals prior to plating and continuous automatic plating processes described. CEM(7a)

Electrometallurgy (7b)

Ontario Refining Company—Electrolytic Copper Plant at Copper Cliff Has Novel Features. E. D. LONEY. *Canadian Mining Journal*, Vol. 51, Mar. 28, 1930, pages 294–296.

The building construction, the tank house and power supply, and the precious metal refinery are outlined and the novel features of the plan pointed out, i. e., plant design is such that it can be easily expanded to take care of double the initial capacity, and the copper has a straight line flow from the blister storage building to the wirebar storage building, where refined copper will be loaded into cars for shipment. Permanent operating crews will probably be employed about midsummer of 1930. WHB(7b)

Silver-Producing Mines of British Columbia. L. V. EARDLEY-WILMOT. *Canadian Mining Journal*, Vol. 51, Feb. 7, 1930, pages 134–135.

Almost all of the silver produced in British Columbia is obtained from silver minerals associated with lead and zinc minerals or less frequently with copper or gold. Most of the ores and concentrates are treated in the Consolidated Mining & Smelting Company's plant at Trail where about 8,000,000 oz. of pure silver bullion are refined annually. WHB(7b)

A New Electrolytic Zinc. F. S. ELFRED, JR. (Evans-Wallower Zinc Co.) *Metal Industry* (N. Y.), Vol. 28, May 1930, pages 223–224.

Read before the Chicago Meeting of the American Die Casting Institute Jan. 1930. Discusses briefly the history and methods of extraction of Zn. The latest method of Zn production is known as Tainton Electrolytic Zn process. Gives a detailed description of the process. VSP(7b)

Electrolytic Iron. (Il Ferro Elettrolitico.) R. B. DAPNIS. *La Metallurgia Italiana*, Vol. 22, Sept.-Oct. 1930, pages 855–869.

General résumé of the subject, with 20 references. Nine photographs are shown of an electrolytic iron plant, designed to produce 800 tons of finished tubing and sheet per year, located at Pont Saint Martin, Italy. This plant utilized the Bouchayer process, similar to that previously installed at Grenoble, France, using cast anodes, but was expected to try out the Eustis and Perrin process for the leaching of pyrrotite or pyrites cinder with $FeCl_3$ and electrolysis of the resulting $FeCl_2$. The plant, however, only ran 6 months, and the company was liquidated. The energy consumption per kilogram of iron produced was 4.5 kwh. It was concluded that the electrolytic iron industry involved no especial technical difficulties, but in peace time has no economic reason for existence. The experience gained is thought to be of value for Italian war-preparedness, since Italy lacks domestic copper for cartridge cases, driving bands for projectiles, etc. for which annealed electrolytic iron might be substituted. HWG(7b)

Electrolytic Production of Metals. (Le developpement et la production electrolytique des metaux.) *Journal du Four Electrique*, Vol. 39, July 1930, pages 256–258.

A survey of electrolytic production of metals taken from the data of T. H. Donahue. JDG(7b)

Preparation of Metal Powders by Electrolysis of Fused Salts. I. Ductile Uranium. F. H. DRIGGS & W. C. LILLIENDAHL (Westinghouse Lamp Co.). *Industrial & Engineering Chemistry*, Vol. 22, May 1930, pages 515–519; *Metal Industry* (N. Y.), Vol. 28, May 1930, page 226.

Presented before the Division of Industrial and Engineering Chemistry at the Atlanta Meeting of the American Chemical Society, Apr. 1930. Bibliography of 17 references. Uranium metal powder was prepared by electrolysis of potassium uranous fluoride in fused calcium and sodium chlorides. The powder was fused to a coherent mass in an evacuated high-frequency induction furnace. Chemical analysis of the metal showed C 0.06%, Fe 0.05% and Si 0.01% as the only impurities. Chemical and physical properties of uranium are listed. MEH + VSP(7b)

Electrolytic Copper Refining. FRANK R. CORWIN & CARLETON S. HARLOFF. *Metal Industry* (London), Vol. 36, June 13, 1930, page 632.

Abstract of paper read before the American Electrochemical Society. See *Metals & Alloys*, Vol. 1, Oct. 1930, page 797. VSP(7b)

METALLIC COATINGS OTHER THAN ELECTROPLATING (8)

Flux Spots and Tin Oxide Blots. WALLACE G. IMHOFF. *Metal Industry* (N. Y.), Vol. 28, July 1930, page 333.

Flux spots on retinned milk and ice cream cans are caused by failure to thoroughly clean the cans, and also to flux which is dirty and contains foreign matter. Tin oxide blots suggest that flux is not in good condition. Pure zinc chloride should be used as flux. Tin bath should be well boiled before starting operations. After cans are removed from pickle, they are to be dipped in liquid tinning flux. Tin pot should be kept clean of tin-dross. VSP(8)

Protection of Iron and Steel by Metal Spraying. *World Power* (London), Vol. 13, Jan. 1930, pages 65–66.

The metallization of iron and steel consists of spraying with aluminum or a similar coating with a view to protection from attack by oxygen at rather high temperatures. The method of metal coating is discussed. (8)

The Destructive Action of Molten Zinc, at and Above Zincing (Galvanizing) Temperatures, upon Metals and Alloys. XI. The Action upon Non-Metallic Materials—General Summary. WALLACE G. IMHOFF. *American Metal Market*, Vol. 37, Oct. 21, 1930, page 11.

A thermometer casing was coated with vitreous enamels and tested in the galvanizing bath. From a commercial standpoint vitreous enamels gave the highest resistance to the action of molten zinc under galvanizing conditions. A complete summary is made in 23 subdivisions, and it is concluded that nothing has been found so far that will entirely withstand the corrosive action of molten zinc at galvanizing temperatures. WHB(8)

Cadmium as a Protection Against Corrosion. A. SIEMENS. *Metal Industry*, (London), Vol. 36, May 2, 1930, pages 481–483.

Translated from *Zeitschrift für Elektrochemie*, Vol. 36, page 110. Cd is used as protective coating for automobiles, aeroplanes, electrical and photographic materials, domestic articles, steel springs, etc. Coating can be produced by dipping material in liquid Cd at 360–380°C. or by application of liquid Cd at 350° C. by means of steel brush. Spraying the liquid metal is also used. Most widely used method is the electrolytic deposition of Cd, from its potassium cyanide complex salt solution. To deposit Cd in a very dense non-porous and bright form, colloids are often added to bath, such as wood fiber, shellac, casein, etc. Cd baths have very good throwing power. Cu is easily coated with Cd, while pure Al requires preliminary treatment. Cd alloys may be prepared electrolytically as protective coatings. VSP(8)

On the Diffusion of Cobalt, Nickel and Chromium into Iron in the Solid State. (Ueber die Diffusion von Eisen mit Kobalt, Nickel und Chrom in festem Zustande.) W. VAN DRUNEN. *Dissertation, Technische Hochschule Stuttgart* (1928), 34 pages.

The introduction of certain elements into the surface of metals and alloys plays an increasingly important role in metallurgy and resulted in processes of commercial significance. In the present quantitative experiments the author throws light upon the relationship between temperature, depth of penetration and concentration of the following systems: Fe-Co, Fe-Ni and Fe-Cr-Ni, by heating cylindrical rods of electrolytic iron in Co, Ni, Co + Ni powder at various temperatures in an atmosphere of hydrogen. The computation of the diffusion coefficients, however did not yield useful data values. The diffusion formula of Fick referring to aqueous solutions does not hold for the crystalline solid state. Corrosion resistant layers could be secured on the surface of Fe corresponding to the composition of standard Cr-Ni steels. EF(8)

The Determination of the Coating of Galvanized Sheet Steel. CHARLES O. GEYER & BENJAMIN E. COHN. *Chemist-Analyst*, Vol. 19, Sept. 1930, pages 4–5.

Two new methods are described. The weighed and measured sample is placed in a beaker in contact with a piece of zinc and covered with 1:10 H_2SO_4 or 1:5 HCl. After 5–10 min. the acid is poured off and the sample washed. Contact with Zn prevents acid attack on the steel. The second method consists of protecting the steel with an organic inhibitor such as "B.B. Inhibitor" or "Red Seal Inhibitor." The sample is immersed in warm acid containing the inhibitor until no more gas is evolved. The protection is not quite complete. CEM(8)

INDUSTRIAL USES & APPLICATIONS (9)

Making High-Pressure Steel Drums in Germany. *Iron Age*, Vol. 126, July 24, 1930, pages 232–233.

Describes construction of high-pressure drums for chemical and other industries by the August Thyssen Hütte Gewerkschaft, a subsidiary of Vereinigte Stahlwerke, A. G. Düsseldorf. The steel is of 50,000 to 64,000 lbs./in.^{2} tensile strength and is best treated during fabrication of drums. They are tested at 350 atmsopheres. Tendency to resist corrosion is claimed as drums are not machined. Ordinary open-hearth steel is used. Made in thicknesses up to 9 mm. and 1700 mm. outside diameter. VSP(9)

Uses of Zinc. *Industrial & Engineering Chemistry*, Vol. 22, May 1930, page 548.

A note citing some of many uses to which this metal is put. MEH(9)

Journal Bearing Practice. FRANCIS HODGKINSON. *Proceedings Institution of Mechanical Engineers*, No. 5, 1929, pages 843–859. Discussion, pages 860–881.

Deals almost entirely with the problem of lubricating the bearing but gives specification for the type of bearing used and properties of metal. RHP(9)

Chromium-Copper Structural Steels. J. A. JONES. *Iron & Coal Trades Review*, Vol. 120, May 2, 1930, pages 718–719.
Abridged from a paper before the Iron and Steel Institute, May 1930. See *Metals & Alloys*, Vol. 1, Oct. 1930, page 799. RHP(9)

Aluminum Alloys for Aircraft-Engine Piston and Cylinder Heads. A. J. LYON. *Transactions American Society Mechanical Engineers, Aeronautical Engineering*, Vol. 2, Oct.-Dec. 1930, pages 257–269; *American Machinist, European Edition*, Vol. 72, July 26, 1930, page 996.
The paper contains results of a great amount of valuable research on aluminum alloys for aircraft-engine piston and cylinder heads that has not heretofore been covered, and the findings should be valuable to all aircraft engine designers. Two alloys have heretofore been recommended, but the Material Division at Wright Field has developed a series of new alloys, and the paper describes the method of manufacture, the effect of numerous alloying constituents on their properties, the strength at elevated temperature, their stability, and the methods of heat treatment, with comparison with the present standard alloys. (9)

Industry's Metals Enter the House. E. C. BADEAU. *Brass World*, Vol. 26, Feb. 1930, pages 31–32; *Sheet Metal Worker*, Vol. 21, Sept. 5, 1930, pages 531–541.
Monel metal is being used more and more in household appliances, particularly for kitchen equipment, fire-places, mantle pieces, radiator covers, lighting fixtures, etc. WHB(9)

Wear and Tolerances on Gages. E. J. BRYANT. *S.A.E. Journal*, Nov. 1930, pages 553–556.
Alloy steel which can be hardened uniformly is recommended as material for gages. Chromium-plating is criticized because it is not bonded to the base material, and tungsten carbide is recommended for some gages in which the wear is extreme. (9)

Iron and Steel for Underground Supports. J. S. CARSON. *Iron & Coal Trades Review*, Vol. 120, June 127, 1930, page 1030.
Abstract of a paper before the Mining Institute of Scotland, Edinburgh, June 21, 1930. Discusses the subject from the mining standpoint. Steel would be cheaper, take less space in shallow seams, last longer, be safer and permit more regular output of coal due to infrequency of falls. RHP(9)

Possibilities of Malleable Iron Castings. W. J. MOLINEUX. *Metallurgia*, Vol. 2, May 1930, pages 7–8.
Small malleable iron castings of intricate design can be cheaply produced. Such castings have the properties of mild steel and are suitable for many engineering uses. Competitive materials are forgings, steel castings and non-ferrous castings. If use of malleable iron is to be extended the quality of castings must be maintained and the costs reduced. Modifications in the annealing process offer the most promise in reducing costs. The short annealing method developed in America and used by the Canadian General Electric Co. is briefly described. JLG(9)

Light Car Engine Pistons. Some Points to Bear in Mind. BASIL BARHAM. *Metal Industry* (London), Vol. 37, July 18, 1930, page 52.
Use of Al for pistons brought about new problems. Al expands more than cast Fe. Al pistons when cold easily fit cylinders, but swell and bind as soon as engine begins to work. Al pistons are made much smaller than cast Fe, consequently at low temperatures, there is a tendency to knock. Piston slap has been cured by use of thicker oil, but in warm weather and on lengthy runs oil has tendency to thin. The matter is up to the designer and manufacturer. VSP(9)

Metal Furniture Output Expanding to Meet Wider Popular Appeal. LOUISE BONNEY. *Iron Age*, Vol. 126, July 10, 1930, pages 75–77.
Development of new alloys in Al and steel has opened new fields to the metal worker. Metal furniture is of outstanding interest since it offers mass production possibilities. Al, rustless steel, monel metal and steel or brass, Cr plated or enameled, are used for furniture. High cost of production will be lowered. Greatest success will come to metal which offers most resistance to the elements. Several companies are now in the field. VSP(9)

Lengthening Rails by Butt Welding. L. C. RYAN (Oxweld Railroad Service Co.). *Journal American Welding Society*, Vol. 9, Sept. 1930, pages 133–141.
Describes process developed for eliminating joints by means of butt welding. Wear of rail ends by battering is eliminated increasing life of rail. Rail creeping is also done away with resulting in great economy. A continuous rail would provide perfect conductor for signal currents without use of the bond. LFM(9)

Constructing Fuselages for Airplanes. E. F. LAKE. *Machinery*, Vol. 36, May 1930, pages 702–708.
Fuselages must be light but strong to support the rest of the plane equipment and to withstand vibration. All joints are welded. An alloy steel fuselage weighing 237 lbs. is equal in strength to a carbon steel of 400 lbs. Chrome-molybdenum is the alloy used by the Buhl Aircraft Co. Duralumin is not as good as steel for this work. RHP(9)

Sheath Wire. F. E. FINDLAYSON (General Electric Co.). *American Machinist*, Vol. 71, Sept. 12, 1929, pages 445–448.
Sheath wire units consist in general, of five parts, the sheath, the coiled resistor, the "cold" terminals, and the insulation. Their maximum temperature is about 1000°F. The units are made by winding a helix of nickel-chromium resistance wire of proper size and length, and attaching the "cold" terminals which are heavy nickel wire. This resistor is inserted in a tube of material suited to act as a sheath. This is filled with finely powdered magnesium oxide and then is reduced in diameter by swaging. This process compresses the magnesium oxide till it is very hard. In this state it is a fairly good conductor of heat but is still an electrical insulator. Discusses the industrial applications. RHP(9)

The Use of Noble Metals for Chemical Apparatus and Laboratory Ware. (Edelmetalle für chemische Apparate und Laboratoriumsgeräte.) J. SPANNER & L. NOWACK. *Metallwirtschaft*, Vol. 9, June 13, 1930, pages 510–512.
The effect of chemicals on Pt, Ir, Pd, Au and Ag are discussed. The use of Pt in the laboratory. Pure Pt is too soft, it can be alloyed with Ir, Rh, Pd, Os or Ru. Pt substitutes consist of Au-Pd alloys or Au + 10 to 15% Pt. Pt is used for electrodes, electrical contacts, in the silk industry and in chemical plants where the purity of the product is essential. Alloys of Ag with Cd and Zn have recently been used. Ag Alloys are used as solder. CEM(9)

Sheet Steel and Strip Steel for Automobile Bodies. JOSEPH WINLOCK & GEORGE L. KELLEY (E. G. Budd Mfg. Co.). *Transactions American Society for Steel Treating*, Vol. 18, Aug. 1930, pages 147–178.
A paper presented before the Semi-annual meeting in New York, Feb. 7–8, 1930. Includes discussion and 44 references. A steel of less than 0.14% C, 0.60% Mn, 0.045% S and P is specified for this work. Alloys have only been used in exceptional cases. Rigidity is obtained by designing the stamping to have high section modulus. The inherent defects in such steel from the melting and rolling and annealing operations are mentioned including ingot segregation, "laminations," and large grain size. Methods of manufacture are briefly discussed. Hot working, cold working of sheets, "stretcher strains" from forming operations and annealing methods are discussed at length. Critical grain growth and decarburization in annealing are discussed. See *Metals & Alloys*, Vol. 1, Aug. 1930, page 691. WLC(9)

Steel Forgings in Design. LAWFORD H. FRY. *Machine Design*, Vol. 2. Sept. 1930, pages 38–41; Oct. 1930, pages 27–31; Nov. 1930, pages 38–40.
Part I briefly discusses basic and acid open hearth processes of steel production and solidification of ingots. Part II deals with the production and heat treatment of forgings. Part III discusses physical properties of steel forgings, also some data on characteristics of a number of alloys. (9)

Manufacture and Application of "Y" and "RR" Alloys. W. C. DEVEREUX. *Nickel Bulletin*, Vol. 3, Sept. 1930, pages 286–293; *American Machinist* (European Edition), Vol. 73, Sept. 27, 1930, pages 77–78.
The manufacture and application of these aluminum alloys are dealt with. See *Metals & Alloys*, Vol. 1, July 1930, page 626. (9)

Aluminum for Threaded Parts. J. D. PORTER. (Aluminum Company of America.) *American Machinist*, Vol. 72, May 8, 1930, page 762.
To prevent seizing of threaded aluminum parts there are 3 methods available. If looseness is not objectionable, a small amount of play may suffice. If a tight fit is necessary, an "anti-seize" compound in the form of paste will be required. This will have to be replaced at each re-assembly. Electroplating of zinc on one of the threaded surfaces will minimize the trouble to an even greater extent and does not require replacement at each separation. RHP(9)

Employing Monel Metal for Machine Parts. E. C. BADEAU. (International Nickel Co.) *Machine Design*, Vol. 2, Oct. 1930, pages 36–38.
The use of Monel metal for machine parts is briefly discussed. Tables give physical and mechanical properties. (9)

Industrial Magnetic Materials for Steady Fields. A. M. ARMOUR. *Electrician*, Vol. 105, Sept. 12, 1930, pages 304–307.
A study of iron and its alloys, heat treatment, output of permanent magnets and cobalt steel castings. Magnetic materials used in industry are classed as: (1) those working under alternating or cyclic changes of magnetization; and (2) those which experience mainly steady conditions of magnetization. This paper deals solely with the latter class. Low-carbon (0.15% C) steel castings are used for stationary parts of dynamo electrical machinery, 0.30% C steel is used for spiders and pole end pieces, and cast iron is used where cost is more important than mechanical strength. Steel forging in the rotating field systems of turbo-alternators, and mild steel for bars and rods. Nickel-iron alloys and special alloys such as monel metal, and Heusler's alloy (14% copper) are used for special purposes. Non-magnetic alloys are used chiefly in alternating fields where their lower permeability give a smaller energy loss than magnetic materials. Cobalt steels of 35% cobalt content are replacing tungsten steel magnets. Steels containing 9% and 15% cobalt, respectively, are sometimes used. Cobalt steel materials require a greater magnetizing force than tungsten steels to obtain maximum magnetic properties. WHB(9)

Wires, Strands and Ropes in the Construction of Aeroplanes. (Drähte, Litzen und Seile im Flugzeugbau.) MARTIN ABRAHAM. *Luftfahrtforschung R. Oldenbourg Verlag*, Vol. 7, May 6, 1930, pages 73–136. Price 13.20 RM.
First, the conception, kind of application and standardization, so far accomplished for wires, strands, and ropes for the particular use in aeroplane construction are explained; the strength of the 3 forms of material are discussed and the different kind of joints and connectors are described in detail. Further elongation and elasticity, torsion under load is treated and testing methods and results described. Tension and its measurement, life of the 3 forms, statistics of accidents, arrangement of guide rolls, and in conclusion, corrosion and surface protection are discussed and some remarks added to replace these elements by other construction elements, for which in particular steel bands are recommended. The whole paper is richly illustrated and very instructive; numerous references are given and a very useful table of comparison of German, English, French and American Standards added. Ha(9)

High-Power Thermal Engines and Materials. (Grossleistungs Wärmekraftmaschinen und Werkstoffe.) A. THUM. *Zeitschrift Verein deutscher Ingenieure*, Vol. 74, June 14, 1930, pages 798–804.
Paper read at the Second World Power Conference in Berlin. In order not to sacrifice safety of operation with modern engines of high power and highest pressures by failures of the material, the usual constructive design based on static values of strength and ample margin of safety no longer suffices. The true reasons for engine failures and fractures must be found and examined. Among these failures are notch-actions which considerably reduce the fatigue strength with alternating and impact stresses; further aging phenomena, faulty material, too low heat-strength, interior stresses and heat stresses. For heat power engines, high-grade pearlite castings must be used, rust-proof steels for nozzles of steam turbines, aging-proof steels for the construction of large boilers. Suitable materials have also been found for explosion engines by systematic research and the danger due to interior and heat stresses could be reduced considerably. Systematic research made it possible to obtain steam turbines to-day with one shaft for 50,000 KW at 3000 RPM and more than 100,000 KW at 1500 RPM; one has succeeded in using safely pressures of 200 at. and steam temperatures of 500° C. Diesel engines can be built for 12,000 KW at more than 200 RPM. Ha(9)

Specialized Manufacture of Parts Aids Small Airplane Builder. *Iron Trade Review*, Vol. 86, Feb. 13, 1930, pages 45–48.
Metal airplane parts such as wing ribs, compression members, ailerons, tail surfaces, bulkheads, and spars are being built by specialized manufacturing methods for small producer. Aerotrus Products Corp., Los Angeles, for example, uses a special high- or low-carbon sheet steel of thin gage, rolled into U-channel sections, in combination with a special trussing design and a new brazing method. A special bronze that melts at exactly the right temperature of the torch and metal being joined is used. Maximum brazing temperature is 1000° F. Government tests have showed the joints to develop the full strength of the metal even after being subjected to 2850 vibrations per min. for 48 hrs. Edward G. Budd Mfg. Co. has developed a wing-rib design, made up of steel Channel section, spot-welded. It has found a non-corrosive steel, of 200,000 lbs./in.^{2} tensile strength, which can be die-formed and electrically welded without selective corrosion or weakness. MS(9)

Advocates Electric Welding of Boilers. *Electrical World*, Vol. 96, Oct. 11, 1930, pages 694–696.
The Babcock & Wilcox Company recommends electric welding of boilers, based on the results of several hundred tests. Characteristics of welds were determined by X-ray and electromagnetic methods. The fusion welding process developed by the B. & W. Co. involves the use of a specially coated low-carbon steel electrode, special automatic and hand equipment for welding and special tests procedure for testing the completed weld. Two non-destroying tests are made. In one the X-ray photographic plant designed by the St. John X-Ray Service Corp. is used and in the other an electromagnetic flaw detector equipment developed in the B. & W. shops by the Sperry Development Co. Characteristics of the B. & W. fusion weld are tabulated and several photographs and photomicrographs shown. WHB(9)

Electrical Uses of Anodic Oxidation. *Metallurgist*, Aug. 1930, page 128.
The June issue of the house organ of the Vereinigte Aluminium Werke reports a new use of anodically oxidized aluminum. The aluminum oxide film formed by anodic oxidation appears to be an exceptionally good electrical insulator. Aluminum wire thus coated can, therefore, be used for carrying high voltages, for the winding of transformer coils and even for the coils of motors and dynamos. VVK(9)

HEAT TREATMENT (10)

Heat Treatment of Steel. (Tratmento termico del acero.) G. SOTO. (Fábrica Nacional de Trubia.) *Anales de la Sociedad Espanola de Fisica y Quimica*, Vol. 28, June 1930, Review Section, pages 129–152.

A general lecture on the fundamentals of heat-treatment, containing examples, data and micrographs from the metallurgical work at the Spanish Gun Factory. Data on Mo in NiCr steels show its effect on the critical points and depth-hardening. HWG(10)

Annealing & Normalizing (10b)

Single-Sheet of Thin-Pack Normalising or Heat Treatment versus Box-annealing of Sheets. R. WHITFIELD. *Sheet Metal Industries*, Vol. 4, July 1930, pages 185–190; Aug. 1930, pages 273–276; *Iron & Coal Trades Reviews*, Vol. 120, May 2, 1930, pages 714–716.

See *Metals & Alloys*, Vol. 1, Oct. 1930, page 800. RHP+AWM (10b)

Malleable Cast Iron. Part 4. J. V. MURRAY. *Metallurgia*, Vol. 2, Oct. 1930, pages 215–217.

Description of the annealing process for producing "whiteheart" malleable castings. JLG(10b)

Recent Developments in Normalizing Sheet Steel. EDWARD S. LAWRENCE (Duraloy Co.). *Transactions American Society Steel Treating*, Vol. 17, June 1930, pages 784–797; *Blast Furnace & Steel Plant*, Vol. 18, Sept. 1930, pages 1455–1460; *Fuels & Furnaces*, Vol. 8, Feb. 1930, pages 191–194; *Heat Treating & Forging*, Vol. 16, Feb. 1930, pages 201–204.

Paper presented before the Semi-Annual Meeting of American Society for Steel Treating, New York City, Feb. 1930. Includes discussion. The paper discusses in general and chronological order several improvements in continuous sheet normalizing furnaces. The advantages of normalizing over box annealing are discussed and lie in shorter time, less fixed charges for equipment, and improved and more uniform quality. The requirements of the automotive industry for sheets of better quality for more intricate stampings have been met by this process. The old blue annealing furnaces have been adapted and improved by the use of better refractories, sectional construction, hearth insulation and the introduction of a conveyor system which has been subject to continuous improvements, making a workable continuous normalizing furnace for sheet steel. Accumulations of scale on the hearth have been greatly reduced by the use of alloy carrier sheets. Further elimination of scale accumulation without the use of carrier sheets is the object of further work which the author reports will soon be ready for publication. The heating cycle has been established to the satisfaction of the metallurgist and its mechanical features improved. A cooling zone has been added to the furnace and its mechanical features worked out to give any desired rate of cooling. The author states that this controlled cooling in the cooling zone will ultimately work out the complete elimination of any necessity for box annealing. In discussion, the author states that further improvements in the conveyors are in process of being worked out and that the economy of treating sheets in 3 hours instead of 3 days will come into its own with perfection of the cooling zone. MS+WLC(10b)

Structure Changes in Annealing Soft Steel. (Gefügeänderungen beim Glühen von weichem Stahl.) W. HEIKE & W. BRENSCHEIDT. *Archiv für Eisenhüttenwesen*, Vol. 4, Aug. 1930, pages 99–103; *Stahl und Eisen*, Vol. 50, Sept. 25, 1930, pages 1362–1363.

In annealing carbon steels in oxidizing atmosphere, the formation of large column-like crystals which grow from the edge to the center is frequently observed. In order to bring about this typical crystallization, the following conditions are necessary: Presence of C, presence of stresses and annealing in an atmosphere which picks up C. The column crystals appear only after having subjected the steel to slight deformations and a subsequent annealing for 3 to 5 hours at temperatures below the α-γ transformation point. The crystals grow larger after having continued the annealing at somewhat higher temperatures for 12–24 hours. As light deformation of not more than 1% is sufficient to start this crystallization at the mentioned heat treatment. A deformation of 3% is most favorable to bring about the effect whereas it disappears at a 6% deformation. The second part of the paper deals with the tendency of P to displace C and the influence which degree of deformation, temperature and annealing temperature exercise. In annealing between A_1 and A_3, C is displaced in the spots high in P, thus leading to a crystal growth after an annealing over a longer period which is due to the diffusion of P. GN(10b)

Case Hardening & Nitrogen Hardening (10c)

Nitriding Investigations. R. SERGESON. *Journal Society Automotive Engineers*, Vol. 26, Jan. 1930, pages 110–111.

Résumé of developments of nitralloy and the nitriding process. The results obtained by nitriding are compared with those obtained by carburizing, with consideration of the effects of various temperatures during the nitriding process. Furnaces, methods, and results are discussed. Nitriding is found to increase the strength of steel. (10c)

Structure of Steels Case Hardened in the Cyanide Salt Bath. (Gefüge im Zyanidsalzbad eingestzten Stahles.) W. HENNIGER & H JURICH. *Stahl und Eisen*, Vol. 50, Sept. 18, 1930, pages 1334–1335.

Whereas former investigations on case hardening of steel in a cyanide salt bath could not prove the presence of nitrogen in the form of nitride needles or a nitrogen eutectoid, the authors were successful in revealing the presence of nitrogen in a low carbon steel which had been cyanide for 5 hours, by etching with a hot sodium picrate solution. GN(10c)

Annealing or Softening of Nitrided Steels by Chemical Decomposition of the Nitride. WILLIAM J. MERTEN. *Transactions American Society for Steel Treating*, Vol. 17, May 1930, pages 638–645.

Paper presented to the Semi-annual meeting of the Society in New York, Feb. 7–8, 1930. Includes discussion. A method of softening nitrided parts for remachining using a salt bath of equal parts of KCl and NaCl at temperatures about 1500° F. is given. The author suggests that the nitrides of the case are decomposed by the molten alkali chlorides to form a gaseous chloride of nitrogen. Micrographs are shown. Denitrided parts may be satisfactorily renitrided. The occurrence of denitriding when parts are exposed to gases of halide compounds in service is discussed. In discussion, the author states that the distortion in renitriding is no greater than in original nitriding. WLC(10c)

On the Carburization and Decarburization of Carbon Steels. TAKEJIRO MURAKAMI & HARUJIRO SEKIGUCHI. *Tetsu to Hagane*, Vol. 16, Oct. 25, 1930, pages 1015–1040.

On heating steels containing 4 different carbon contents, 0.29%, 0.70%, 1.02% and 1.29%, at 800°, 900° or 1000° C. with different packing materials, the conditions of carburization or decarburization of carbon steels were studied by the change of weight and of the microstructure of specimens, before and after the heating. When the carbon content in steels exceeds about 0.5%, the decarburization takes place at 800° on heating with charcoal powder, though it is not decarburized, if the temperature is higher than 900° or carbonate is mixed in the charcoal. If air penetrates through the packing material during heating, the decarburization is conspicuous. The carburization is markedly energized by adding Na_2CO_3 or $BaCO_3$. When the carbon content in steel is more than that corresponding to the A_{cm} point, the rate of carburization is very sluggish, even when a powerful carburizing agent is used. The presence of a small amount of moisture in the charcoal powder tends to promote the carburization, while the size of the powder seems to have practically no effect provided it is fine within a certain limit. TM(10c)

Quenching (10d)

The Quenching of Steel. *Metallurgist*, July 1930, pages 100–102.

An extended abstract of French's work on the quenching of steel published in the June Transactions of the American Society for Steel Treating. See *Metals & Alloys*, Vol. 1, Jan. 1930, page 344. VVK(10d)

Aging (10f)

The Artificial Aging of Duralumin and Super-Duralumin. K. L. MEISSNER. *Engineer*, Vol. 150, Sept. 19, 1930, page 319.

Abstract of paper read before the Institute of Metals, Sept. 10, 1930. See *Metals & Alloys*, Vol. 1, Nov. 1930, page 850. LFM(10f)

Question of Age Hardening Based on Experiences with Iron Alloys. (Zur Frage der Vergütung auf Grund der Erfahrungen mit Eisenlegierungen.) W. KÖSTER. *Zeitschrift Verein deutscher Ingenieure*, Vol. 74, Aug. 2, 1930, pages 1100–1101.

Paper read before Deutsche Gesellschaft für Metallkunde, dealing with a historial review, and a discussion as to which properties can be improved by a suitable heat-treatment. The etching effect and some chemical phenomena which are not quite elucidated are discussed Ha(10f)

Age-Hardening. MARIE L. V. GAYLER. *Metallurgist*, June 1930, pages 91–93.

If a supersaturated solid solution is formed in an alloy when it is quenched from a high temperature, and if the alloy is left at room temperature, or possibly at some higher temperature, then age-hardening may occur. The most important theory for this phenomenon is the "precipitation" theory. This theory attributes age-hardening to the precipitation, in a highly dispersed state, of particles from a supersaturated solid solution. The objections to this theory have been (1) lack of microscopical evidence of the presence of precipitated particles, and (2) the fact that age-hardening at room temperature is accompanied by an increase in electrical resistance, while aging at higher temperatures is accompanied by a decrease in electrical resistance; which, it is claimed, suggests that a process of solution takes place at room temperature, but precipitation at higher temperatures. The first objection has been removed by definite microscopic evidence of particles of the compound $CuAl_2$, which has been precipitated during the aging of a copper-aluminum alloy. X-ray investigation indicates that the crystal lattice is being severely distorted during the process of age-hardening, and that great stresses are being set up within the crystals. This is accompanied by an increase in electrical resistance. It is suggested that precipitation from the supersaturated solid solution takes place in two stages; (1) the rejection of the atoms of the dissolved metal from the lattice of the solid solution, accompanied by the possible formation of molecules, and (2) a "coagulation" of these rejected atoms or molecules, resulting in the formation of minute crystallites of a second phase. X-ray investigations on various alloys, examples of which are given, and changes in hardness and electrical conductivity supports this theory. The author concludes that the facts which have been established regarding the changes which take place during age-hardening are strong confirmation that hardening it due to the precipitation of highly dispersed particles. JOINING OF METALS & ALLOYS (11)

Brazing (11a)

Brazing Spelters. NEVILLE DEANE. *Metal Industry* (London), Vol. 36, May 23, 1930, page 559.

Gives method and mixtures used. VSP(11a)

Welding & Cutting (11c)

Training Course for Aircraft Welders. R. W. BOGGS (Union Carbide Co.) & S. C. CLARK (Linde Air Products Co.). *Journal American Welding Society*, Vol. 9, June 1930, pages 62–76.

Outlines training course for aircraft welders based on established principles of procedure control. Figures are given showing the shop work layout for each lesson. LFM(11c)

Welded Steel Structures. EDWARD DARCE LACY. *Metallurgia*, Vol. 2, Oct. 1930, pages 201–202.

Gives reasons why a welded structure is preferable to a riveted structure. JLG(11c)

Shrink-Stresses and Their Care in Arc-Welding. (Schrumpspannungen und deren Beachtung beim Lichtbogenschweissen.) LOTTMANN. *Zeitschrift Verein deutscher Ingenieure*, Vol. 74, Sept. 20, 1930, pages 1340–1345; *Elektroschweissung*, Nov. 1930, pages 205–214.

The causes of production and the conditions for the magnitude of shrinking in arc-welding are described and practical shrinking values are given in the form of a curve which can be used for working on large pieces of from 5–12 mm. thickness. The danger is pointed out of clamping a piece tightly when welding and the direction of tensile and compression stresses as a function of the rigidity of the piece, of direction and sectionalizing of welding is explained. In conclusion, practical directions are given for the selection of tools and how to proceed in order to limit shrinking stresses. Ha(11c)

A Fourteen-Story Office Building Field Arc-Welded in Boston, Mass. FRANK P. MCKIBBEN (General Electric Co.). *General Electric Review*, Vol. 33, Dec. 1930, pages 699–705.

The design, the erection, field welding, the qualification of welders, the inspection, and other data are discussed. WHB(11c)

Electric Welding by the Carbon Arc. J. C. LINCOLN. *Journal American Institute Electrical Engineers*, Vol. 49, Feb. 1930, pages 110–113.

The author discusses the butt welding of steel sheets by the C arc process. Autogenous welding is divided into 2 main classes; gas and electric. Electric arc welding is divided into 2 classes: metallic and C arc. Gas and metallic arc welding in general require beveling of plates for butt weld while C arc welding does not. The controlling variables in C arc welding are (1) amperes in the arc, (2) voltage across the arc, (3) magnetic field about the arc, (4) atmosphere about the arc, (5) speed of feed and (6) filling-in material. Discussion is given of the effect of each of these variables of the resulting weld with special reference to the action of a magnetic field parallel to the direction of the arc upon the current in the arc and the effect of the atmosphere about the arc on the ductility of the resulting weld. (11c)

Welding Combined with Foundry Practice. W. H. NAMACK & H. M. HOBART. *General Electric Review*, Vol. 33, Dec. 1930, pages 674–676.

Electric welding is employed with much advantage in: (1) ship building construction, (2) steel bridge construction, (3) pipe line construction, (4) construction of various kinds of machinery such as machine tools, electric motors, generators, transformers and switch gear, and (5) construction of pressure vessels. The article purports to call attention to the industrial value of combining the accumulated experience in the foundry and welding arts, and of usefully applying this united experience to the development of the foundry art to a high degree. WHB(11c)

The Welding of Copper. *Industrial Chemist*, Vol. 6, May 1930, page 198.

A satisfactory method for welding copper has been developed which differs slightly in technique from that used on ferrous materials, and employs a copper alloy filler rod and an appropriate flux. It is necessary to use a special copper which is not attacked by the gases of the acetylene flame. The special materials are supplied by Imperial Chemical Industries Ltd., who have developed the process. MPB(11c)

Fusion Welding of Aluminum. *American Machinist*, Vol. 72, June 5, 1930, page 927.

Very brief, condensed summary of part of the present knowledge of fluxes, rods and methods of procedure in fusion welding of aluminum. RHP(11c)

Extracts Report on Strength of Welded Joints in Tubular Members for Aircraft. H. L. WHITTEMORE & W. C. BRUEGGEMAN (U. S. Bureau of Standards). *Journal American Welding Society*, Vol. 9, Sept. 1930, pages 107–132. 21 references.

Report No. 348 of the National Advisory Committee for Aeronautics. See *Metals & Alloys*, Vol. 1, Dec. 1930, page 914. LFM(11c)

Electrically Welded Cranes and Their Official Certification. (Elektrisch geschweisste Krahne und ihre behördliche Genehmigung.) E. ROSENBERG. *Zeitschrift Verein deutscher Ingenieure*, Vol. 74, Sept. 20, 1930, pages 1345–1348.

Paper read at the Convention in Vienna of the Verein deutscher Ingenieure. Eight electrically welded bridge cranes and 2 rotating cranes are described and illustrated by many photographs which have been built by several Austrian builders. Ha(11c)

Metallic Electrodes for Cast-Iron Arc Welding. SHUN-ICHI SATOH (Mitsubishi Research Lab.). *American Institute Mining & Metallurgical Engineers, Transactions Iron & Steel Division* (1929) pages 144–165.

Includes discussion. Gray or white iron can be deposited by using an electrode consisting of wrought iron coated with a mixture of SiC and graphite. The coating should preferably consist of SiC and C with 1% barium carbonate bound with water glass. Contains 17 references. JLG(11c)

Building Up Battered Ends of Rails. W. H. KIRKBRIDE (Southern Pacific Co.). *Journal American Welding Society*, Vol. 9, Sept. 1930, pages 69–77.

Either the oxyacetylene method or the electric arc method can be used for welding rail ends. Difficulties encountered by oxyacetylene process are eliminated by electric arc method. The rail and joint bars are not heated and welders do not need such elaborate training. Welding is done with high C welding rods which deposits material with C content similar to that of original rail. Oxyacetylene process is still used by Southern Pacific Company but only for scattered jobs. Inspections have shown that battered joint properly welded by electric arc process, using 0.90–1.10 C coated welding rods, do not batter as rapidly as original rail, due to the higher C contents of the rod. LFM(11c)

Job Shop Welding. H. L. FETTER (Rochester Welding Works). *Journal American Welding Society*, Vol. 9, June 1930, pages 59–61.

Outlines various fields in which welding has been found useful. In up-to-date welding shops it is possible to weld successfully alloy steels, stainless steels, acid-resisting iron, aluminum, monel metal, stellite and copper and bronze mixtures of every nature. LFM(11c)

Fusion Welding of Aluminum. *American Machinist*, Vol. 72, May 29, 1930, page 885.

Gives diagrams of the various types of flames of both oxy-acetylene and oxy-hydrogen. Briefly discusses the use of the torch and gives tables to aid the beginner in selecting the proper size of tip. Oxy-hydrogen when it will supply sufficient heat will produce a cleaner weld. The Oxy-acetylene will give higher temperatures and is, therefore, more widely useful. RHP(11c)

Methods of Testing Welds. GEORGE B. MOYNAHAN. *Metals & Alloys*. Vol. 1, July 1930, pages 607–612; *Metallurgist*, Sept. 1930, pages 143–144.

Detailed description of methods of preparing specimens and technique of (1) tensile tests for strength, (2) bend tests for strength, (3) pressure test for soundness, (4) hydrostatic pressure test, (5) pressure qualification test, (6) inspection tests of etched specimens, (7) reheating tests, bend test for ductility and (8) special tests. More thorough testing of welding is recommended. ESC+VVK(11c)

Resistance Welding of Steel Joists. FRANK BURTON. *Journal American Welding Society*, Vol. 9, Sept. 1930, pages 78–87.

For resistance welding there should be available from 200–300 kilowatts of current for each inch² of surface to be welded, and the pressure should be between 8,000 and 10,000 lbs./in.² of weld. Time may be varied between $^1/_5$ and $1^1/_2$ seconds. Just before current is applied pieces to be welded are forced together at pressure of 2000 lbs./in.² which is quickly raised to 8000–10,000 lbs./in.² after current is applied. Result is perfect fusion of metal at junction which is free from slag or oxide. Plain butt weld is ideal resistance weld. Strength of such welds in tension is 93 or more percent of strength of the original bar. Gives results of tests made upon various types of welded steel joists. In making resistance welds, a slight coating of rust or other foreign matter appears to be essential to the process as it causes localizing of heat at the point of contact. Good welds can be made with steel containing 0.05–0.06% S. Recent tests indicate that sound and reliable butt welds may be made in steels up to 0.65% C. Mn content of 0.40–0.60 is satisfactory for steel of C content 0.15–0.25%. In low C steel, the weld metal is fine grained sorbite. In steel of higher C content, a small amount of poorly developed troostite is found explaining the greater hardness of the weld metal over the original stock. LFM(11c)

The Influence of Current Conditions in Electric Arc-Welding of Soft Steel. (Einfluss der Schweissstrombedingungen bei der elektrischen Lichtbogenschweissung von weichem Flussstahl.) Experiments on Melting Conditions, Tensile Strength Tests, Testing of Welding Defects with X-Rays. N. LEFRING. *Forschungsarbeiten auf dem Gebiete des Ingenieurwesens, Verein deutscher Ingenieure*, No. 332 (1930) 53 pages, 67 references.

Next to the skill of the welder and the character of the materials, that is, the kind of electrode and the metal of the product, the most important factor for the quality of the joint by electric arc-welding is the proper adaptation of current conditions, intensity and kind of current and for direct current also the current direction. The present investigation was primarily directed toward determining the relation between current conditions and fusing process in welding steel, and further in ascertaining in which way the quality of the weld is influenced by current conditions. From numerous tests with alternating current and direct current with either polarity of the electrode it could be stated that the fusing capacity of the electric arc does not change materially with the voltage of the arc, that is, length of the arc, but depends mainly on the current intensity. A fusing number K could be derived in g./amp./min. which was for alternating current 0.177, for direct current with minus electrode 0.161. with plus electrode 0.227. From these values, a basis could be found for the calculation of time required for welding. The quality of the welded seams was tested by determining tensile strength, impact strength, and X-ray pictures were taken from different angles; all these tests are reproduced in numerous tables, diagrams and photographs. A reference to literature on the same subject (mostly German) concludes the exhaustive treatise. Ha(11c)

Electric Welding. JAMES CALDWELL. *Electrician*, Vol. 104, Feb. 21, 1930, page 229.

A brief review pointing out the superiority to riveting, the large saving in cost, and the application to shipbuilding. Discussion brought out the need of a reliable field test for a welded joint. WHB(11c)

Talks on Silver Solders

Chapter I. Characteristics.

As America's leading producer of Silver Solders we are glad to give the readers of METALS & ALLOYS up-to-date information on these important brazing alloys.

"Handy" Silver Solders are supplied in twelve standard guaranteed compositions containing from 10% to 80% silver and melting at from 1325° F. to 1600° F. They flow freely, penetrate quickly and make strong joints (40,000 to 60,000 lbs. per sq. in.) that resist corrosion, vibration and shock.

Silver brazing can be done on all metals fusing above the melting point of the silver solder employed.

Various phases will be discussed in future chapters. Meanwhile, send for our interesting and informative *Bulletin No. 3MA*.

WORKING OF METALS & ALLOYS (12)

Melting & Refining (12a)

A Study of the So-Called "Overreduced" Condition in Molten Steel. J. V. McCrae, R. L. Dowdell & Louis Jordan. *Bureau of Standards Journal of Research*, Vol. 5, Nov. 1930, pages 1123–1149.

A study was made of 4 heats of acid electric steel for castings in which 2 heats were in the so-called "overreduced" state while the others were in the normal condition as made according to general practice. The 2 types were investigated as regards temperature of the molten metal, structure, and physical and chemical properties. The lower fluidity or "runability" of the overreduced (overdeoxidized) steel manifests itself in a short "filming-over time" with the melters' spoon test. This is apparently caused by the rapid formation of silica, which rises from the steel because of the addition of excess metallic silicon to an oxidized steel. This phenomenon may also be the cause of incorrect judgment of its temperature, since its emissivity is higher than that of a clean liquid steel surface. (12a)

Manufacture of Duplex Steel. *Iron & Coal Trades Review*, Vol. 120, June 6, 1930, pages 913–914.

From the article entitled: "Practice in Making Duplex Steel" by J. E. Carlin, published in *Iron Age*, Mar. 27, 1930, pages 925–927. See *Metals & Alloys*, Vol. 1, Oct. 1930, page 802. RHP(12a)

Aluminum and Magnesium as Deoxidizers. Edmund Thews. *Metal Industry* (London), Vol. 36, May 23, 1930, pages 547–548.

Chief advantages of Al as a deoxidizing agent are its affinity for O, measured by its heat of combustion generated by its action with O, is greater than any other except Mg, and its quantitative deoxidizing capacity measured by the O taken up by a standard unit. Its disadvantages are that at heat of melting process Al_2O_3 does not rise to the surface immediately, as in case of Mg and Si, and that it has affinity for Pb. Mg is being used as deoxidizer in melting Cu and Ni alloys since Mg is highly inflammable at ordinary temperatures of brass melting, Mg-Cu alloys are used for deoxidizing purposes. Other alloys used are Mg-Zn with 50% Mg, Mg-Sn with 50% Mg and Mg-Ni with 50% Mg. VSP(12a)

New Deoxidation Process for Red Brass. W. Reitmeister. *Metal Industry* (London), Vol. 36, May 2, 1930, page 479.

Abstract translation from *Giesserei*, 1929. Raw material is examined as to whether it is over-carburized or oxidized by adding coal dust to molten metal. If properties of metal are deteriorated, the metal is over carburized. A slag containing CuO or ZnO is added to reduce C and to oxidize metal. Then deoxidation with coal dust is carried out. VSP(12a)

The Musso Steel Process. C. E. Parsons. *Canadian Mining Journal*, Vol. 51, Mar. 14, 1930, pages 242–245.

The Musso process provides for the manufacture of steel ingots by the production of sponge iron with melting in suitable furnaces for the purification of the sponge iron and its conversion to steel. Coal is used as fuel and the gas from it and the carbon monoxide produced in the furnace provide the heat for the reduction retort, the operation of the auxiliary apparatus and the melting and steel-making furnaces. A substantial amount of gas of high-heat value is available for outside use. The capital investment is less than 1/2 that of existing plants for making steel ingots. The manufacture of ingot steel by the Musso process costs 20% less than by the open-hearth process and the steel is equal to high-grade electric steel costing twice as much. The process is described, construction features noted and chemical reactions and concentrating and melting of iron outlined. WHB(12a)

The Effect of Melting Conditions on the Graphite Size and Microstructure of Gray Cast Iron. A. L. Norbury & E. Morgan (British Cast Iron Research Association.) *Foundry Trade Journal*, Vol. 42, May 15, 1930, pages 357–359; *Fuels & Furnaces*, Vol. 8, Aug. 1930, pages 1083–1084.

Part of a paper read before the spring meeting of the Iron and Steel Institute. See *Metals & Alloys*, Vol. 1, Sept. 1930, page 736. MS+VSP(12a)

Physical Chemistry of Steelmaking. *American Institute Mining & Metallurgical Engineers, Transactions, Iron and Steel Division* (1929) pages 233–259.

"Round table" discussion of the physics and chemistry of steel making processes with particular reference to the open-hearth process. At New York, Feb. 1929. JLG(12a)

Electrical Melting Improves Quality and Cuts Cost. *Electrical World*, Vol. 95, May 10, 1930, pages 948–949.

The first vertical-ring induction furnace for melting nickel-silver in Naugatuck Valley went into service last year. Results show an improved quality of alloy and lower melting costs. The life of the lining has increased from 400 heats to more than 800 heats, or 500,000 lbs. per lining. WHB(12a)

Clean Steel. H. W. Gillett. *Metals & Alloys*, Vol. 1, Dec., 1930, page 866.

An editorial commendation of the investigation by C. H. Herty on the physical chemistry of steel making. ESC(12a)

Melting of Steel in a Brackelsberg Furnace with Acid Lining. (Das Schmelzen von Stahl auf saurem Futter im Brackelsberg-Ofen.) P. Bardenheuer. *Stahl und Eisen*, Vol. 50, Sept. 18, 1930, pages 1328–1330.

Report of the Kaiser Wilhelm Institut für Eisenforschung. Temperatures up to 1800° C. can be obtained in the Brackelsberg furnace by using a simple checker, which preheats the combustion air from 200° to 300° C. by utilizing the waste gases. In this way steel can be melted in a furnace with acid lining. The advantages of the Brackelsberg furnace, as originally found in melting cast iron, apply also for melting steel. The steel of the Brackelsberg furnace is distinguished by excellent mechanical properties, as well as good casting properties. The fuel consumption for melts of about a ton of steel is not higher than that for large open-hearth furnaces. Therefore, the Brackelsberg furnace is superior to any other steel melting furnace of the same capacity. GN(12a)

Acid Open Hearth or Basic? K. R. Binks. *Iron & Steel Industry & British Foundryman*, Vol. 4, Nov. 1930, pages 53–54.

The same physical properties can be attained by both types of steel if precautions in manufacture are taken since material in both types of open-hearth furnaces is exposed to similar influences during melt down. CHL(12a)

Duplex Practice. J. E. Carlin (Union Drawn Steel Co.). *Transactions American Society for Steel Treating*, Vol. 17, May 1930, pages 631–637.

The paper discusses slag metal reactions, pig iron addition for deoxidation, tapping, and ladle technique in the basic open hearth using acid Bessemer hot metal. The removal of the oxidizing slag and preparation of a neutral or reducing slag as in the electric furnace process is suggested for finishing such steel. See *Metals & Alloys*, Vol. 1, Oct. 1930, page 802. WLC(12a)

Operation of an Open-hearth Furnace. Part I. Construction and Equipment. Part II. The First Charge. Part III. Fuels. M. J. Conway. *Iron & Steel Engineer*, Vol. 7, March 1930, pages 135–141; May 1930, pages 230–234; July 1930, pages 368–371.

The first of this series of lectures delivered for the benefit of the employees of the Open Hearth Department of the Lukens Steel Company covers the construction of the open-hearth furnace, the arrangement and uses of the various accessory equipment. The second covers a discussion of the preparation of the furnace for its first charge, the materials of the charge and their order of addition, the duties of the attendants, the working period and repair materials. The third discusses the fuel problem particularly as to the use of fuel oil. WLC (12a)

The Preparation of the Metal for Steel Castings in the Converter. J. Leonard. *Foundry Trade Journal*, Vol. 42, June 19, 1930, pages 458–459.

Paper read before annual convention of Institute of British Foundrymen. Operation in converter is to produce liquid steel from liquid pig Fe, air is brought in contact with liquid metal whereby they are oxidized as follows:

$$C + O_2 = CO_2 + 8100 \text{ Cal.}$$
$$Si + O_2 = SiO_2 + 6429 \text{ Cal.}$$
$$Mn + O = MnO + 1653 \text{ Cal.}$$

Addition of calories necessary because: (1) Metal remains 15 or 20 min. in converter and loses some of its calories by radiation; (2) Blast is cold and absorbs from the metal bath calories; (3) Melting point of steel is higher than pig Fe. Law of masses and of affinity govern chemical reactions of converter. From observation the following conclusions are evident: (1) Composition of pig Fe is of importance as the elements Si, Mn and C play part of purifiers; (2) Initial temperature of operation should be suitable; (3) In order to prevent excessive solution of FeO, too high temperature should be avoided; and (4) from start to finish combustion must be carefully controlled. VSP(12a)

Phosphorus as a Deoxidizer. Edmund Thews. *Metal Industry* (London), Vol. 36, April 11, 1930, pages 401–402; April 25, 1930, pages 449–450.

Describes particularly phosphor bronze, its preparation, applications and influence of nature and properties of alloys to which it is added. Apart from phosphor Cu, other P alloys are rarely used. Good results are obtained with a process devised by Heyn and Bauer. Technical application of phosphor Cu. P as deoxidizer is superior to other deoxidizing agents in that only small traces of this element are retained by the metals. Disadvantages become evident only if P is added in excess. Increased temperature range of solidification is due to excess use of P. Gives method of adding phosphor Cu to melts. Influence of phosphor content on bronzes. The changes of mechanical properties of bronzes induced by small % of P vary directly with Sn contents of alloys. Tabulates results of tests made on 2 rolled phosphor bronzes containing traces of P. On account of its corrosion resistance phosphor bronze is used for making tanks, vats and machine parts. VSP(12a)

Improvements in the Utilization of Aluminum Scrap in the United States. (Neuerungen bei der Behandlung von Aluminiumschrott in den Vereinigten Staaten.) Robert J. Anderson. *Metallwirtschaft*, Vol. 9, Oct. 17, 1930, pages 863–866.

Contains 2 references. The use of Al scrap in the U. S. has risen to 45,000 tons annually. 50% scrap is often used in making castings. In a plant for reworking scrap Al proper sorting of different alloys is very important and is done very cleverly by experienced operators. In some cases chemical analysis, electrical resistance measurements or hardness tests are also used. After classifying, foreign metals, Fe, brass, etc., are removed and mixtures are made to obtain definite compositions. Filings are pulverized, screened and put through Steinlein separators. The separated oxide is sold for manufacture of chemicals. Turnings are freed from oil and Fe and pressed into briquets weighing 30 to 60 lbs. The charges are melted in reverberatory furnaces of 5 to 25 ton capacity. The heavy scrap is melted first, flux added, then turnings and briquets and the mass stirred. The process is not continuous. Gas, coal or coke is used. Considerable experience and close technical control are essential for success. CEM(12a)

Methods for Determining the Volume Changes Undergone by Metals and Alloys During Casting. C. M. SAEGER, JR. & E. J. ASH. *Transactions & Bulletin American Foundrymen's Association*, Vol. 1, June 1930, pages 107–145.
True shrinkage data were not obtained by the sand-cast-core methods. The more accurate experimental method depends on the construction of the specific volume-temperature curve for the metal under consideration. The liquid contraction curve is constructed from data secured by application of the crucible immersion method. The mass of liquid metal at the temperature of filling the crucible at room temperature. The liquid specific volume is, therefore, easily calculated. The solid contraction curve is constructed from data given by observation of the change in length with temperature change of a sand-cast bar of metal. The solidification shrinkage of an alloy is the difference in specific volume at the beginning and end of freezing range. (12b)

Crystallization and Segregation Phenomena in 1.10 Carbon Steel Ingots. (Kristallisations-och Segringfenomen i 1.10 Kolstalsgüt.) AXEL HULTGREN. *Jernkontorets Annaler*, Vol. 114, March 1930, pages 95–158.

Modern Die-Casting Practice. ERNEST V. PANNELL. *Engineer*, Vol. 150, Aug. 15, 1930, pages 168–169; Aug. 22, 1930, pages 193–194.
Describes various types of die-casting machines giving diagrams illustrating 2 types. For dies it is necessary to have steel capable of resisting effect of molten metal many times per hour at the melting temperature of Sb, Pb, Zn and Al. For first 2 metals, a low-C steel is satisfactory. For Zn a higher C heat treated steel is used but for Al a special alloy steel is necessary. Cr-V, Ni and W-Cr steels have been used. Recently a die steel has been used of 4–8% W and 3% Cr. Shrinkage allowed for on the dies takes into account fact that their working temperature is 350° C. while that of molten Al is 700° C. In case of Zn, die temperature will be about 220° C. and metal 440°. After forging and before cutting, die-blanks are normalized and annealed. W-Cr steel is heated to 1010° C., air-cooled and tempered at 565°C. Practice is being developed of Cr plating the die surfaces which prevents oxidation and gives greater life to the die and a better finish to the final castings. After tempering, Brinell hardness of dies should be 400–440. Discusses development of die-casting metals and alloys giving summary of alloys adopted for test by the American Society for Testing Materials. LFM(12b)

Moulding and Casting. J. ELLIS. *Foundry Trade Journal*, Vol. 42, May 8, 1930, pages 348; May 29, 1930, pages 397–398, 408.
Paper read before the Scottish Junior section of the Institute of British Foundrymen. It is important that facing-sand be mixed and made correctly for each job. Bad strips, scabs, mapping, blow-holes, streaky veins, are all due to badly mixed facing-sand. Best results are obtained when molds are poured with hot metal. Core plates should be placed well below the casting. If plate is too close contraction is impeded and casting cracks. Using block points over chipping strips is advantageous. By using top runners only, there is a danger of crown of mold scabbing by the force of metal dropping. This is avoided by pouring about a ton of metal in at the bottom. Anchoring cores and sealing joints. Other topics discussed are: Condenser molds, pipes without chaplets, pulley and lettering castings, core venting and burning on. VSP(12b)

Rolling (12c)

Rolling Mill Analysis. E. KIEFT (Illinois Steel Co.). *Iron & Steel Engineer*, Vol. 7, June 1930, pages 258–265.
The author gives a mathematical analysis of the reduction of metal in a rolling mill accompanied by diagrams and sample calculations. Discusses the relations of size of work to size and weight of the rolls. WLC(12c)

Practical Suggestions for Rolling Shapes. (Praktische Ratschläge für das Walzen von Formeisen.) H. RUPPE. *Stahl und Eisen*, Vol. 50, Oct. 9, 1930, pages 1430–1431.
The article gives a general discussion on the best type of mill for special shapes, describes a special device to avoid warping of shape due to the difference of the working diameters of the rolls and points out the usefulness of alloy steel rolls. GN(12c)

Equipment for Measuring Rolling Pressure. (Vorrichtung zur Druckmessung an Walzwerken.) E. VOIGT & W. LUEG. *Mitteilungen Kaiser Wilhelm Institut für Eisenforschung*, Vol. 12, Report 154 (1930) pages 161–164; *Stahl und Eisen*, Vol. 50, Oct. 9, 1930, pages 1442–1443.
The authors designed a simple instrument to measure the rolling pressure in rolling mills. An elastic measuring box, filled with mercury is deformed by the rolling pressure, thus displacing the mercury into an attached tube of small cross-section. This tube is provided with contact points which are connected with electric bulbs. The course of the rolling pressure can also be registered. Rolling pressure curves were taken in cold rolling soft steel. The instrument is suitable for supervising the rolling process. GN(12c)

Rolling an Ingot into a Billet in 19 Carefully Planned Passes. F. G. GASCHE (Bethlehem Steel Co.). *Iron Age*, Vol. 126, August 7, 1930, pages 351–352.
From a paper read before the Association of Iron and Steel Electrical Engineers at Buffalo, June 17, 1930. Gives diagrams showing surface contour of rolls and end view of tapered ingot. It was estimated that work required to produce the billets was 24 kwh. a ton. VSP(12c)

The Theory of Rolling Plastic Materials. F. G. GASCHE (Bethlehem Steel Corp.). *Iron & Steel Engineer*, Vol. 7, June 1930, pages 325–339.
The author gives a mathematical study of rolling mill practice including discussion of cluster mills for sheet and plate. Stresses in the material being rolled and in the rolls are analysed. Energy requirements are calculated. The theory is applied to the calculations for a 34 in. reversing blooming mill. WLC(12c)

Forging (12d)

Economy in the Forge Shop. (Betriebswirtschaft in Schmiedebetrieben.) H. KLINAR. *Stahl und Eisen*, Vol. 50, Oct. 9, 1930, pages 1425–1430.
Report No. 77 of the Rolling Mill Committee of the Verein deutscher Eisenhüttenleute. Investigations on the fuel consumption of forge furnaces show that the fuel loss is generally very high due to the varying size of the heated pieces. This condition could be improved by the use of movable furnaces or furnaces provided with a partition wall. Good heat insulation, regular charging and uniform heating times are of importance as well as a suitable distribution of the men in charge of the forge hammers. The steam consumption of the hammers, used directly for forging cannot yet be measured, but is approximately calculated from the number of blows. GN(12d)

Extruding (12f)

Continental Practice in Non-Ferrous Metals Extrusion. *Metal Industry* (London), Vol. 36, June 20, 1930, pages 645–646.
Discusses progress made in Sweden, Norway, Italy and Germany. Greatest progress has been made in Sweden. British machinery methods are preferred. Metals used include 70:30 and 60:40 cupro nickel, aluminum, etc. (To be continued.) VSP(12f)

Machining (12g)

The Future of Tungsten Carbide as a Cutting Tool. WILLIAM H. MCCOY. *S.A.E. Journal*, Vol. 27, Nov. 1930, pages 557–559.
The savings realized on a number of other jobs are tabulated. Some classes of work are enumerated in which failures have been encountered, and some causes of these failures, and remedies for them are said to be found in large tips and annealed shanks. As no one type of tool steel has been found suitable for all jobs, the author predicts that a number of varieties of tungsten carbide will be developed, differentiated by modifications in the binder and graduations in the grain sizes of the tungsten-carbide particles. This will make it possible to select a tool material suitable for the job, instead of picking out jobs that can be done by the material. 9 references. (12g)

Tungsten Carbide Tools. ROGER D. PROSSER. *Transactions American Society for Steel Treating*, Vol. 17, June 1930, pages 749–764.
Paper presented before the Boston Chapter of the Society, June 1929. Discusses results obtained in actual production work with tungsten carbide tools. Practical recommendations as to use, brazing and grinding of such tools are given. The author warns against their indiscriminate use without regard for the conditions to be met in the service. WLC(12g)

Finest-Machining of Metal Pieces. (Feinstbearbeitung von metallischen Werkstücken). O. SCHLIPPE. *Zeitschrift Verein deutscher Ingenieure*, Vol. 74, Sept. 20, 1930, pages 1329–1339.
The importance of the quality of the surface of machine parts sliding upon one another is emphasized; the methods are described to measure the depth of traces on the surfaces remaining from the machining processes. Various methods are described for the finest finishing processes, as grinding, boring, lapping, polishing (manually and automatically) of cylindrical and flat parts and of cranks, gears, etc., of "honing" for polishing crank-shafts, the draw-grinding of cylinder bores, cold-rolling of bearing supports of shafts and the press-finish of holes. The paper is profusely illustrated and has 12 references. It is, however, pointed out that these delicate methods should be applied only if absolutely necessary; a curve shows the costs of a piece as function of the required tolerances, and economy has to decide up to which degree of accuracy one can go. Ha(12g)

Sawing Armor Plate with a Carboloy Saw. *Machinery*, Vol. 36, May 1930, pages 721–722.
Taken from the April number of *Carboloy*. In a test for the Navy Department a saw equipped with carboloy tooth points was used for cutting a strip of treated armor plate 16 inches thick, 9 feet across, and 17 feet long. Describes saw construction. The saw was run 12 hours without resharpening and without a coolant. Later experiments proved it better to use a lubricant. See *Metals & Alloys*, Vol. 1, Sept. 1930, page 737. RHP(12g)

Machines for Tungsten-Carbide Tools. *Machinery*, Vol. 37, Sept. 1930, page 48.
Summarizes the suggestions made regarding the construction of machines to be used with tungsten-carbide tools. RHP(12g)

New Applications of Tungsten-Carbide Tools. *Machinery*, Vol. 36, July 1930, pages 892–894.
The Machine Shop Practice Division of the American Society of Mechanical Engineers at the semi-annual meeting at Detroit, June 9–12 devoted an entire session to papers and reports on Tungsten-Carbide tools. This is a brief review of that session. Discusses the use of tungsten-carbide; in lathe tools, for saws, for heavy machine tools. Present applications, materials for which it may be used, machine equipment, tool sizes, grinding of tungsten-carbide tools, cutting speeds, results and failures of tools. RGP(12g)

Machinability and Tensile Properties of Steel and Cast Steel. (Zerspanbarkeit und Festigkeitseigenschaften von Stahl und Stahlguss.) A. WALLICHS & H. DABRINGHAUS. *Zeitschrift Verein deutscher Ingenieure*, Vol. 74, Aug. 30, 1930, page 1220–1221.
As characteristic of the machinability is designated the cutting velocity per hour V_{60} which requires a change of cutting tool after 1 hour. These values are plotted as function of the feed of the tool, and from the curves it can be deduced that doubling of the feed causes doubling the reduction in cutting velocity as is caused by doubling the depth of the chip. Further, the tests showed that the machinability of usual materials of the same kind and same strength is the same and hardly changed by normal alloying elements nor by changing of structure by heat-treatment. Ha(12g)

New Developments in Machining Aluminum and Its Alloys. R. L. TEMPLIN. *S.A.E. Journal*, Nov. 1930, pages 548–552.
Comparatively large rake and clearance angles required for best results leave a relatively thin cutting-edge on a cutting tool for aluminum. One difficulty encountered is that tools of such form are not always available or suitable, for various reasons; for instance, small tools of various types are available only with cutting edges suitable for steel and bronze, and the desirable amount of top rake cannot well be provided on circular form-tools. Tool bits of various sorts can be reground to the desired angle. A simple round form of tip that is shown can be utilized in tools for various purposes, including use as inserted teeth in a face-milling cutter. High-speed-steel tools are suitable for most aluminum alloys, but alloys containing a high percentage of silicon can be machined to advantage only be using cemented tungsten-carbide. Machine tools should be suitable for high speed. Rigidity is required and lost motion must be prevented to guard against a tendency of the thin points of the tools to dig into the work. 16 references. (12g)

Haynes Stellite Cutting Tools. W. A. BECKER, E. E. GORDON & W. A. WISSLER (Haynes Stellite Co.). *Preprint* No. 7, Dec. 1930 Meeting, *American Society of Mechanical Engineers*, 6 pages.
The red-hardness of the Co-Cr-W alloy, Stellite No. 3, for machine tools (composition not stated) is compared with that of high speed steel. From about 400° C. up, Stellite is the harder. At 800° C. Stellite shows about 50 Rockwell C, while high speed shows about 12. The Monotron hardness tester is preferred for determination of high temperature hardness. Stellite has been successful on machining cast, high-test and malleable irons; mild steel, if the tool and the work have sufficient rigidity; and some miscellaneous materials, but is not successful on alloy steels, or in automatic or semi-automatic machines for cutting steel. Comparisons are made with high speed steel for milling, boring and turning cast iron and mild steel, and for turning bronze, to show increased production per unit time and per grind, through the use of Stellite tools. "Their successful operation depends on the proper ratio of speeds, feeds and methods of application. In milling, hardness of material machines, kinds of fixtures used, condition and strength of machine, nature of castings, proper selection of cutters and proper cutting and clearance angles have an important bearing on final results." (12g)

Machining Properties of Some Cold-Drawn Steels. O. W. Boston (University of Michigan). *Preprint* No. 9, Dec. 1930 Meeting, *American Society of Mechanical Engineers*, 12 pages.

Fifteen cold-drawn steels, including S.A.E. Nos. 1112, 1120, 1230, 1315, 2320 and 6141, "super-free-cutting" screw stock with 0.20% S and a 0.35% C, 1.70% Mn with low sulphur and a higher carbon type of S.A.E. 1320, as well as an 0.06% C, 13.4% Cr low sulphur stainless, and a free-machining 0.09% C, 15.2% Cr, 0.46% S, 0.25% Mo composition, were studied by observing the forces required in planing, in drilling, and in a milling, the last being observed by use of the Oxford pendulum tester, which cuts a chip with a single tooth, the energy being read in a manner similar to impact testing. Drill penetration was also observed. The low-sulphur stainless was about twice as difficult to machine, by all the tests, as the usual cold-drawn stock. The presence of the S and Mo in the free-cutting type, brought the machinability close to that of usual stock. The 2320, 6140 and low-S, high-Mn alloy steels in most of the tests were appreciably more difficult to machine than the usual stock. In all the other plain carbon and high-Mn, high-S stocks, the general trend was for better machinability the higher the Brinell in the range covered, 156 to 207. The finish left on the different steels by a shaper tool was studied to some extent. Tool life was not studied. While general trends were consistent on the whole, there were many variations, and the relative machinability of 2 steels depends on what type of machining is in question, on the nature and form of the cutting tools, on size of tool, depth of cut and feed, on the lubrication, on the composition, structure and degree of cold working. In the operation of milling, cutting with or against the feed may show as much variation in energy required as do steels of quite different compositions and structures milled in the same direction. Tools of different composition vary in the results obtained on the same steel when milling with and against the feed. The size of the bar, i. e., the degree of cold working, did not appear to be a major variable, the results for different sized bars of the same material generally showing good agreement. In the drill penetration tests, the whole series of steels was tested with one drill, not re-sharpened. The slight dulling of the drill was found to be less of a variable than the difference in the action of the same drill after re-grinding, even on a machine. The data are given in tables and curves, too extensive for reproduction. Micrographs are shown of all steels studied. HWG(12g)

Cemented Tungsten Carbide as Applied to Cutting Tools. L. J. St. Clair (Carboloy Co.). *Preprint* No. 50, Dec. 1930 Meeting, *American Society of Mechanical Engineers*, 5 pages.

Cemented tungsten carbide, beside extreme hardness, has the highest compressive strength and highest modulus of elasticity of any known material, low electrical conductivity, and a thermal coefficient of expansion only $^1/_2$ that of Invar. In the use of cemented tungsten carbide machine tools, the proper clearance angle is very important, and the machine and tool set-up must be rigid. The material is only about $^1/_2$ as strong in transverse rupture test. This fact, plus its high modulus, makes the material refuse to bend without breaking. Failure to comply with the need for rigidity is one of the chief causes for tool failure. Rigidity in the set-up of the grinding machine used for dressing the tools is also important. Light pressure and slow feed with wheel surface speed at about 5000 ft./min. are preferable for grinding. HWG(12g)

The Problem of Machinability Measurements. E. S. Herbert. *Metallurgia*, Vol. 2, Sept. 1930, pages 169–171; Oct. 1930, pages 206–208; Vol. 3, Nov. 1930, pages 13-15.

After reviewing many possible ways of measuring machinability, the author explains Taylor's formula $V\ T^n = C$, in which V is the cutting speed in ft./min., T is the tool life in min., and C is a constant depending on the cutting conditions other than speed. French and Digges adopted this method and took the value of $^1/_7$ for n, but no qualitative relationship could be found between the "Taylor Cutting Speed" and the hardness, tensile and other physical characteristics of the steels. The problem of machinability has been attacked by several investigators working on the assumption that the machinability of a metal can be measured by the force or forces on the tool used to cut it. Thus the forces on a planer tool have been measured by O. W. Boston (University of Michigan); the forces on a lathe tool by Dempster Smith (Manchester) and by Boston, Wallichs, and Schlessinger; while the torque exerted by a twist-drill when drilling holes in metals has been measured by these investigators, and by Patkay (Charlottenburg), and by Benedict and Hershey (University of Illinois). A form of permissive feed test for machinability introduced by the author has the merit of not involving the use of any but standard workshop equipment, while the test can be made by any mechanic. This test consists in making a cut with a gravity fed hack saw through a bar of standard diameter, 2 in., and counting the number of strokes in cutting through the bar. In making the test it is advisable to use a saw blade sharpened to a standard shape of tooth on an automatic saw-grinder, and to use a newly sharpened blade for each test. "Machinability" cannot be determined by any simple test. A study of chip formation and chip hardness shows that in some cutting a keen and efficient cutting edge of the metal cut is formed on the tool. Due to this edge blunt tools are frequently more efficient than sharp tools. Hardness measurements of the chips with the pendulum tester show that many anomalies can be explained by variations in work hardening capacity. JLG+GTM(12g)

Tool-Steel Tools. A. H. d'Arcambal (Pratt & Whitney Co.) *Preprint* No. 16, Dec. 1930 Meeting, *American Society of Mechanical Engineers*, 8 pages.

Some general principles in the design of cutting tools of high-speed steel are discussed. Sketches show clearances of a few lathe tools, and reamers, taps, dies, milling cutters, slitting saws and form cutters briefly discussed from the point of view of design of the tool. In reaming and tapping, the same size tools will produce holes and threads of different dimensions depending on the material cut and the lubricant used. The usual compositions of plain carbon tool steel, and of vanadium or chromium alloy tool steel, and of three oil-hardening, non-deforming tool steels are given. The water-hardening tool steels give better results in service than the non-deforming steels. The usual precautions for heat treatment of regular high speed steel, are given and the advantages and disadvantages of cobalt additions are pointed out. Since large bar stock cannot be made at present without harmful segregations, forgings should be used for large tools. Microstructures and fractures are illustrated to show the superiority of forgings. Microscopic inspection of all incoming shipments of tool steel is necessary if the tool manufacturer is to control his product properly. In d'Arcambal's opinion, electric furnace alloy and high speed steels are superior to those made in crucibles. Emphasis is put on the necessity for care in grinding tools so as to prevent formation of grinding cracks. HWG(12g)

The Present Status of Cemented Tungsten Carbide Tools and Dies. Zay Jeffries. *Transactions American Society Mechanical Engineers, Machine Shop Practice*, Vol. 52, Jan.-Apr. 1930, pages 29–37.

After discussing the origin, production and properties of cemented tungsten carbide, the author takes up the matter of utilizing the material in cutting tools. Its adaptability for wire-drawing and blanking dies is brought out, as well as its ability to cut hitherto unmachinable materials such as glass, porcelain, asbestos products, etc. Data are given on the life of cemented tungsten carbide tools as compared with older types of tools on a varied assortment of machining jobs, following which the author concludes with a brief consideration of the commercial situation and the future possibilities of the material. See *Metals & Alloys*, Nov. 1929, pages 222–225. (12g)

Drawing & Stamping (12h)

The Drawing of Monel Metal Tubes. Edward S. Richards. *Metal Industry* (London), Vol. 36, May 23, 1930, page 552.

Monel metal has a composition of 67% Ni, 28% Cu and the remaining 5% made up of Fe, Mn, Si, etc. It must be annealed in closed furnace pot. Passes should be lighter than those given to brass owing to hardness of the metal. Tallow is used as lubricant; in finishing passes rape oil and tallow mixed. After tube becomes hard it is annealed at 800° C. and cooled. It is pickled in dilute vitriol, with HNO_3. Steel used for dies must be hard and close grained to withstand wear. Gives typical examples. VSP(12h)

The Manufacture of Thin-Wall Tubing. William S. Lyhne (Fulton Sylphon Co.), *Machinery*, Vol. 36, July 1930, pages 860-864.

A machine designed by Fulton and Giesler of the Fulton Sylphon Co., Knoxville, Tenn. is being used successfully for drawing tubing with a wall thickness of 0.004" and a diameter from 1" to 9". Loss from scrap due to parting or breaking of tubes is less than 1%. The former draw-bench method brought losses as high as 35%. The tube as it passes through this machine is subjected to both a pulling and pushing action. Instead of continuous motion the tube is given a series of intermittent movements each equal to 8". Gives detailed description and illustration of the construction and working of the machine. This process has been commercially applied to zinc, brass, aluminum and copper. Zinc which usually is difficult to draw can be drawn to the same length and wall thickness as other metals with this machine. RHP(12h)

On Surface Stretching, Formation of Folds and Prevention of Folds during the Drawing of Hollow Bodies. (Ueber Oberflächendehnung, Faltenbildung und -verhinderung beim Hohlgefässziehen.) F. Fischer. *Dissertation, Technische Hochschule Stuttgart* (1927) 64 pages.

This thesis for a doctor's degree is intended to throw light upon the relationship between stretching, formation of folds, dimensions of the material to be shaped, thickness of sheets and the lubricant. Emphasis is placed on the selection of a proper lubrication medium and the superiority of Muzin was established. The diagram of drawing radii of Kaczmarek proved to be a valuable aid in the shaping process. The formation of folds is principally caused by the application of incorrect drawing edge radii, by the application of an unsuitable lubricant and too large a pressure of the sheet holder. The superiority of the pneumatic sheet holder was proven and new conversion tables valuable in the drawing process are established. EF(12h)

Cold Working (12j)

Cold Work and the Physical Properties of Metals. *Metallurgist*, June 1930, pages 85–86.

A very complete abstract of the paper of R. L. Templin at the Cleveland meeting of the American Institute of Mining and Metallurgical Engineers which is also abstracted in *Heat Treating & Forging*, Vol. 16, March, 1930. See *Metals & Alloys*, Vol. 1, Mar. 1930, page 430. VVK(12j)

The Cold Rolling of Strip Steel. S. Badlam. *Advance Copy, American Iron & Steel Institute*, Oct. 1930, 80 pages.

Extended description of the process, with special reference to its development from the historical point of view. The history of backed-up rolls in cluster mills and of exerting tension on the strip simultaneously with rolling is especially dealt with. HWG(12j)

The Strain Hardening of Some Materials during Cold Rolling. (Die Verfestigung einiger Werkstoffe beim Kaltwalzen.) E. Greulich. *Stahl und Eisen*, Vol. 50, Oct. 2, 1930, pages 1397–1401; *Iron Age*, Vol. 126, Dec. 18, 1930, page 1832.

The decrease of the physical properties of the following materials was studied during cold rolling: 5 carbon steels with 0.12–0.61 carbon, a 5% nickel steel, 3 chromium steels (12.56–15.36% Cr), a chromium-nickel steel (35.20% chromium, 10.50% nickel) and monel metal. The reduction of area amounted up to 50%. The results are: hardness, yield point and elongation are heavily influenced at reductions of 1%. The tensile strength and reduction of area do not increase unless a reduction of 6% is obtained. The largest amount of the changes of the physical properties takes place for deformations up to 10%; still larger deformations do not bring about an essential change. Hardness, yield point and tensile strength follow an exponential law for deformations up to 30%. By means of this law it could be proven, that the strain hardening of the carbon steels is independent of the carbon content. Alloy steels, providing they have a pearlitic structure, do not strain harden more than plain carbon steels. Austenitic chromium-nickel steel and monel metal can be much more strain hardened, which leads to the conclusion that structural and atomic composition have a certain influence on the strain hardening process. VSP+GN(12j)

Cleaning (12k)

Cleaning Metal for Painting. E. Palin Spruance (American Chemical Paint Co.). *S.A.E. Journal*, Vol. 27, Sept. 1930, pages 366–367.

Removal of rust, oil, grease, soldering compounds and paint preparatory to painting of automobile bodies is considered. (12k)

Production Cleaning. Tom L. Wheeler, Jr. (Hobart Mfg. Co.) *Metal Cleaning & Finishing*, Vol. 1, Dec. 1929, pages 651–656, 666.

The factors which govern the selection of proper equipment for cleaning are: the type of foreign matter to be removed, the composition of the metal, the size of the parts, the operations immediately preceding and following cleaning, the maximum temperatures to which the cleaning bath can be heated, and the quantity to be cleaned. Describes various types of cleaning equipment and points out their applications and method of operation. In most designs, the principle utilized is that of the movement of the cleaning solution over the work. This is accomplished by various means, the spray system being preferable. In general, washing machines are of the flat conveyor type or the rotary drum type. Describes also auxiliary equipment, such as driers and rinsing units. MS(12k)

Polishing & Grinding (12l)

Manufactured Abrasives. F. L. Nobes. *Industrial Chemist*, Vol. 6, May 1930, pages 183–184.

A discussion of the history, manufacture, and chemical and physical properties of silicon carbide (carborundum) and fused alumina. MPB(12l)

Finishing Stainless Steel. Jack Pearsall (Hanson-Van Winkle-Munning Co.). *Machinery*, Vol. 36, July 1930, pages 870–872.

Stainless steel cannot be polished by the same operations which are used for cold-rolled carbon steel. For ordinary stainless steel use: 1. Soft face cloth wheel coated with abrasive grain No. 60 to 70, wheel surface speed of 6500 to 7500 ft./min. 2. Soft face cloth wheel, abrasive grain size No. 100 to 120, the cut should cross the previous one, same wheel speed. 3. Same type wheel and speed, abrasive grain size No. 150 to 200. Use a light lubricant and cut across previous cut. 4. Softer wheel than those used before, same speed, No. 200 to 220 abrasive, cut across previous cut. Use plenty of lubricant. 5. Method called "bobbing" is preferable. Mix No. 220 grain abrasive with a heavy machine oil to a heavy consistency, use this with a bullneck, walrus or sheepskin wheel without abrasive coating. 6. Buff with high-count sheeting buffs such as 88/88 or 84/92 at surface speeds of 10,000 ft./min. Care must be used in all operations not to apply too much pressure or to over-heat the work. RHP(12l)

Coloring (12m)

Colored Metals. JULIUS GRANT. *Metal Industry* (London), Vol. 36, April 25, 1930, page 450.
Metals may be colored by plating, either electrolytically or mechanically, by chemical reaction, or by painting or enameling. Future developments will take place along the lines of plating and chemical reaction. By chemical methods there is the greatest scope for ingenuity in production of colors on metals. Very little has been done on the method. Oxide films are best known examples of chemical coating. Other methods of coating are: rolling or welding metal sheets together, zinc coating and spraying. VSP(12m)

Sand Blasting (12n)

Metal Abrasives. A. B. MCDANIEL. *Metals & Alloys*, Vol. 1, July 1930, page 614.
Steel shot and grit are manufactured by a variety of different firms, a list of which is included. Various uses are enumerated. Data on production over the past ten years are included. ESC(12n)

DEFECTS (13)

Intercrystalline Cracking in Steam Boilers Cause of Many Boiler Explosions. *Iron & Coal Trades Review*, Vol. 120, June 20, 1930, page 988.
Abstract of a paper entitled, "Intercrystalline Cracking in Steam Boilers," by F. G. Straub before second World Power Conference at Berlin. RHP(13)

The Heterogeneity of Steel and the Relationship of Macrographic Examination. ROGER POWELL. *Iron & Steel Industry & British Foundryman*, Vol. 3, Sept. 1930, pages 369–371; Vol. 4, Oct. 1930, pages 29–31.
Roughly classified, heterogeneity encountered in steel of miscellaneous sizes and sections are mechanical defects, crystal growth and chemical segregation. Mechanical defects are mainly pipes, roaks and seams. CHL(13)

Some Common Defects in Steel for Gear Manufacture. FRANCIS W. ROWE. *Metallurgia*, Vol. 2, Oct. 1930, pages 198–200.
Gears must be made from exceptionally high quality steel. The hot acid test should be applied to all steels used for gears. Some of the common defects revealed by this test are: residual pipe, "V" segregation, rim segregation and ingot corner weakness. Other frequent defects are slag inclusions and variation in analyses. JLG(13)

Defects in Cast Brass Are Revealed by Deep Etching. W. F. GRAHAM & L. A. MEISSE. *Foundry*, Vol. 58, July 1, 1930, pages 92–93; *Metal Industry*, (N. Y.), Vol. 28, June 1930, page 287; July 1930, pages 331–333.
Abstracted from a paper read before the American Foundrymen's Association in Cleveland, May 12 to 16, 1930. Describes some typical results obtained in deep etching non-ferrous metals and alloys, especially brasses and bronzes. Tests confined chiefly to red brasses, alloys containing Cu, Sn, Pb, and Zn of about 85–5–5–5. Deep etching does not only reveal inclusions and character of metal from an oxidized standpoint, but also porosity, lamination or actual fissures. Contamination of red brass by Fe promotes serious difficulty in machining operation. Porosity in castings can be determined quickly by etching. VSP(13)

Normal and Abnormal Steel. (Normaler und abnormaler Stahl.) E. HOUDREMENT & H. MÜLLER. *Stahl und Eisen*, Vol. 50, Sept. 18, 1930, pages 1321–1327, 20 references.
Report 166 of the Material Committee of the Verein deutscher Eisenhüttenleute. The paper gives a summary on the present state of the problem of abnormal steel with special reference to the American investigations. In case-carburizing low carbon steel failures are observed which are due to the appearance of soft spots which did not harden. All abnormal steels harden uniformly by quenching them in brine, so that there are practically no difficulties in hardening abnormal steels. The appearance of soft spots is in relation to a slight change of the critical cooling velocity, which occurs in rimmed or effervescing steels. Killed steel is always normal. All these alloying elements like Mn, Cr, Ni which cause a decrease of the critical cooling velocity eliminate all characteristics of an abnormal steel. Other alloying elements favor abnormality. The terms normal and abnormal should not be used to determine the quality of a steel, and the case-carburizing test is not sufficient to pass on normality or abnormality of a steel. GN(13)

CHEMICAL ANALYSIS (14)

The Determination of Calcium by Ignition of Calcium Oxalate to Carbonate in Air. H. H. WILLARD & A. W. BOLDYREFF. *Journal American Chemical Society*, Vol. 52, May 1930, pages 1888–1892.
Ignition of calcium oxalate was studied at 350, 400, 450, 500, 550 and 600°. Between 450 and 500 the oxalate is quantitatively converted into carbonate in 1–2 hours. This is made the basis of an accurate method for the gravimetric determination of calcium. A simple method is described for adjusting the furnace temperature by utilizing the melting points of silver chloride (455) and lead chloride (501). MEH(14)

The Micro Determination of Halogens and Metals in Organic Compounds. H. H. WILLARD & J. J. THOMPSON. *Journal American Chemical Society*, Vol. 52, May 1930, pages 1893–1897.
The micro method is based upon the oxidation of the sample with fuming sulphuric acid. The halogen is distilled into alkaline arsenite and then precipitated as silver halide. Metals may be determined in the same solution from which the halogen has been removed. The whole process is simpler and more rapid than in the macro method. MEH(14)

The Use of Ortho, Para-Dihydroxy-Azo-Para-Nitrobenzene as a Test for the Magnesium Ion. EDWARD WILLIAM ENGEL. *Journal American Chemical Society*, Vol. 52, May 1930, pages 1812–1814.
A new technique for the use of o,p-dihydroxy-azo-p-nitrobenzene as a test for the magnesium ion is described. It is found that the test is valid in the presence of any one of all of the common cations met with in qualitative analysis and in a great many combinations of these cations. Ni, Co, or both do not confuse the test. Acetates, tartrates and ammonium salts do not interfere but increase the sensitivity of the test. The test can be used most efficiently as a substitute for the classical magnesium ammonium phosphate method. According to the method and technique described, it is claimed that 0.003 mg. of Mg can be detected. MEH(14)

Determination of Iron in Aluminum. G. AGAMENNONE. *Giornale di chimica*, Vol. 12, October 1930, pages 486–487.
To avoid errors due to presence of Ti in the usual methods involving titration of ferrous Fe, titration of ferric Fe is advised. A 5 g. sample is dissolved in 50 cc. H_2O + 75 cc. concentrated HCl, diluted to 250 cc., filtered, and a 100 cc. aliquot taken, to which 5 cc. H_2O_2 is added. After boiling 15 minutes, the Fe is precipitated by sodium bicarbonate, the solution neutralized with HCl, and 3 g. KI added, the flask stoppered, cooled and allowed to stand 25 minutes. The liberated I is then titrated with $n/10$ sodium thiosulphate (1 cc. = 0.002792 g. Fe) and starch indicator. No analyses are given to compare this with other methods. HWG(14)

HISTORICAL & BIOGRAPHICAL (15)

Fifty Years in Iron and Steel Works. W. OGDEN DAYSON. *Proceedings Institution of Mechanical Engineers*, No. 5, 1929, pages 1061–1067.
Abridged from an address before the South Wales Branch, in Swansea, Nov. 13, 1928. Discusses progress of the industry under the heads of: apprenticeship, fitting shops, foundries, other shops, capacity, blast furnaces, hot-blast stoves, blast engines, iron mills and steel. RHP(15)

Ancient Egyptian Implements. *Iron & Coal Trades Review*, Vol. 120, May 30, 1930, page 873.
Brief abstract of a paper entitled: "The Metallography of Some Ancient Egyptian Implements" by Sir H. C. H. Carpenter & Dr. J. M. Robertson. Presented before the Iron and Steel Institute, May 1930. See *Metals & Alloys*, Vol. 1, Sept. 1930, page 739. RHP(15)

Pewter: Its History, Development and Manufacture in the United States. FRANCIS A. WESTBROOK. *Metal Industry* (London), Vol. 36, May 2, 1930, pages 477–479.
Includes a brief historical review. Art of making pewter began in America about the middle of the 17th century and flourished until the middle of the 19th century. Roman pewter averaged about 75% Sn and 25% Pb. Late French and English pewter was a mixture of 100 parts Sn and 5 parts Cu for the better grade, and 100 parts Sn and 15 parts Pb for the poorer grade. Modern No. 1 alloy contains 90.7% Sn, 7.8% Sb and 1.5% Cu and is used for hammered objects with minimum amount of raising. No. 2 alloy has 92% Sn, 5% Sb and 3% Cu. Considers present day manufacture. VSP(15)

The Early Use of the Metals. T. A. RICKARD. *Journal of the Institute of Metals*, Vol. 43 (1930) pages 297–365.
Includes discussion. See *Metals & Alloys*, Vol. 1, Sept. 1930, page 739.(15)

ECONOMIC (16)

The World's Resources of Tungsten. (Världens wolframmalmtillgångar.) HARALD CARLBORG. *Jernkontorets Annaler*, Vol. 114, Sept. 1930, pages 455–490.
Discussion of occurrence, uses, consumption, prices, geographical distribution and statistics. HCD(16)

The Supply of Minerals and Metals. *Iron & Coal Trades Review*, Vol. 120, June 27, 1930, page 1027.
Abstract of the presidential address of James G. Lawn before the Institution of Mining and Metallurgy in London, June 1930. The address was "Periodical Variations in the Price of Minerals and Metals." RHP(16)

The Tungsten Situation and Its Effect upon High-Speed Steel Prices. *Machinery* (London), Vol. 35, Jan. 2, 1930, page 456.
The effect of ferrotungsten ore prices on the tool steel industry is discussed. Consideration is given the reasons for the increase in price and the outlook for the future. The key to the situation seems to lie in China and, when it is known through what channels regular supplies can be obtained from that country, a clearer view of the situation should be possible. (16)

The Malayan Tin Position. B. SOMERSET. *Metal Industry* (London), Vol. 36, April 25, 1930, pages 451–452.
The Federated Malay States is the richest tin bearing country in the world, producing about 1/3 of world's total supply. Practically all known methods of mining are in vogue. The largest output of Sn is still obtained by means of gravel pumping. The highest price ever recorded for tin was $212.00 per pikul in Feb. 1920. A comprehensive plan of research for 1930 announced. Gives production and delivery statistics for a number of years. VSP(16)

French Ironmaster Association. *Iron & Coal Trades Review*, Vol. 120, May 30, 1930, page 874.
Annual report of the Comite des Forges de France for 1929. Comments on the trade symptoms of the last few months. RHP(16)

Conditions in the Continental Iron and Steel Industry. *Iron & Coal Trades Review*, Vol. 120, June 27, 1930, pages 1032–1033; Vol. 121, July 4, 1930, page 10; July 11, 1930, pages 40–41.
Extracts from the report of a delegation on the "Industrial Conditions in the Iron and Steel Industries in France, Belgium, Luxemburg, Germany and Czecho-Slovakia" issued by the Economic Advisory Council. Discusses war, and post-war conditions in the above countries. Deals largely with labor and wage conditions. RHP(16)

Antimony in 1929. PAUL M. TYLER. *Mineral Resources of the United States* (1929) Part 1, *United States Bureau of Mines*, Oct. 22, 1930, pages 45–56.
Domestic consumption of new antimony rose in 1929 almost to the high point of 1926. No shipments of domestic antimony ore were reported, the entire producton of 3052 tons (25,669 tons antimonial lead) being a by-product from lead smelters. Of this, 2311 tons of antimony (17,062 tons antimonial lead) were from domestic ores. The recovery of secondary antimony was 11,131 tons. AHE(16)

Economic Relations of Silver to Other Metals in Argentiferous Ores. CHARLES WHITE MERRILL, *et al.* *Economic Paper* 10, *United States Bureau of Mines* (1930) 29 pages.
Silver-bearing ores which produce 91% of the world's silver also produce 85% of the world's gold, 69% of the lead, 66% of the copper and 46% of the zinc. Silver contributes 10.4% to the gross value of this group. The % of the total world's silver production contributed by ores whose silver content represents the indicated proportion of the value of the ore is as follows: silver 0–10% of ore value, 12.3% total silver production; 10–20, 21.0; 20–30, 10.3; 30–40, 9.0; 40–50, 5.0; 50–60, 1.7; 60–70, 5.4; 70–80, 8.3; 80–90, 16.9; 90–100, 10.1. More than 1/2 the total silver production is from ores to which silver contributes less than 1/2 its value, and 1/2 from the 0 to 20% classes. A table shows the % of value contributed by each of the other metals in the above classes. Analyses of the ores by countries and districts are given. AHE(16)

Gold, Silver, Copper, Lead and Zinc in Colorado in 1928. CHAS. W. HENDERSON. *Mineral Resources of the United States*, 1928, Part 1, *United States Bureau of Mines*, October 21, 1930, pages 817–872.
The gross value of the gold, silver, copper, lead and zinc recovered in Colorada in 1928 was $16,375,355, a decrease of 3.5% from 1927. There was a nominal increase in the output of gold, an increase of 10.5 % in silver production, an increase of 67% in copper output, a decrease of 26% in the production of lead and a decrease of 5% in zinc. AHE(16)

Gold, Silver, Copper, Lead and Zinc in Arizona in 1928. C. N. GERRY. *Mineral Resources of the United States*, 1928, Part 1, *United States Bureau of Mines*, Oct. 15, 1930, pages 761–815.
In 1928 the mines of Arizona produced gold, silver, copper, lead and zinc worth $114,300,381, the largest production of these 5 metals of any state. Copper represented 92% of the total value. The total increase of $15,509,424 over 1927 was due almost entirely to copper as the output of gold, lead and zinc decreased 4, 28 and 50%, respectively. The quantity of silver decreased slightly, but the value increased more than 2%. Of the total copper produced, 52% was obtained from concentrates, 37% from crude ore smelted, and 9% from ore leached. AHE(16)

PLANTS & LABORATORIES (17)

Layout Aids Non-Ferrous Production. EDWIN BREMER. *Foundry*, Vol. 58, July 15, 1930, pages 48–51, 84.

Describes plant of the American Manufacturing Co., Dayton, Ohio, manufacturers of non-ferrous castings. Casting range from 1 oz. to 1000 lb. and include the well-known No. 12 and other Al alloys, the 85–5–5–5, 88–10–2 and 80–10–10 bronzes, Mn bronze, yellow brass and acid resisting bronze. Foundry has a capacity of 1,000,000 lbs. of castings a year. Red metals and Al cast in separate foundry bays. Well illustrated. VSP(17)

Produces Cores with Speed and Accuracy. F. B. PELCHER. *Foundry*, Vol. 58, July 1, 1930, pages 88–91.

Describes coremaking at the Kenosha, Wis. foundry of the Nash Motor Co. Equipment includes 7 continuous gas fired ovens—3 horizontal and 4 vertical. Each of the horizontal ovens has a capacity of from 60 to 80 core racks. Two ton crane distributes the sand. Core breakage is negligible as a result of a continuous conveyor system. Economy in core baking in horizontal ovens. Tabulates data on vertical core ovens. VSP(17)

Battelle Institute Houses Several Metallurgical Researches. *Iron Age*, Vol. 126, July 10, 1930, pages 89–91, 131.

Established by the will of the late Gordon Battelle. It is a non-profit agency with ample funds. Dr. H. W. Gillett is director, with C. E. Williams as associate director supervising work on fuels, ores smelting, and O. E. Harder in charge of work on metals and alloys. The L-shaped building is erected on the outskirts of Columbus, facing Ohio State University's farm. Its proximity to the University is advantageous. Several investigations are already underway, financed by industrial organizations. VSP(17)

Constant Growth Marks History of Sievering Plating Plant. *Metal Industry* (N. Y.), Vol. 28, June 1930, pages 269–270.

Oldest jobbing plant in New York adds 10,000 ft.^{2} of space. New 5000 ampere generator has been installed for Cr plating. VSP(17)

Galvanizing Works of Messrs. Baldwins, Limited, at Hereford. *Iron & Coal Trades Review*, Vol. 120, Jan. 10, 1930, page 47.

Describes the new galvanizing plant which was opened Jan. 1, 1930. The plant handles about 200 tons of material per week. RHP(17)

The Heat-Treatment of Locomotive Parts. W. A. STANIER. *Proceedings Institution of Mechanical Engineers*, No. 5 (1929) pages 1069–1073.

Abridged from an address delivered before the Western Branch in Bristol on Dec. 11, 1928. Briefly describes a metallurgical plant at Swindon. (The plant is not named.) Gives a chart diagram showing heating and quenching temperatures for the heat-treatment of straight carbon steels. Photomicrographs illustrate the structure of axle steel under various conditions. RHP(17)

At the Dunswart Iron and Steel Works. *South African Mining & Engineering Journal*, Vol. 41, March 8, 1930, pages 45–47.

Some of the up-to-date additions to this steel foundry are described and illustrated. AHE(17)

MACHINERY & SUPPLIES (18)

Welding Reduces Production Times for Jigs from Weeks to Days. J. R. WEAVER (Westinghouse Elec. & Mfg. Co.). *Electric Journal*, Vol. 27, Sept. 1930, pages 506–508.

In addition to time saving a reduction in cost of about 25% is secured where machine jigs are made by arc welding. The jig parts are assembled by a mechanic, properly squared and tack-welded, sufficiently to hold them together and then turned over to the welder. The jigs are normalized by heating to 1000° F. and allowed to cool in the air. WHB(18)

New Electroplating and Cleaning Conveyor. *Brass World*, Vol. 26 Sept. 1930, page 238.

Sargent & Co. of New Haven, Conn., have marketed an automatic machine for electroplating, pickling and cleaning in large scale production. Speed, quality of work and economical operation are claimed for the machine. Two illustrations are shown. WHB(18)

New Acetylene Generators for Gas Welding. (Les nouvelles centrales a acetylene pour la Soudure Autogene.) *Journal du Four Electrique*, Vol. 39, May 1930, pages 176–177.

In large acetylene generators producing 50–100 m.^{3} per hour carbide falls in water giving relatively cold gas. The mud, 20–30 liters per kg. of carbide, is continuously ejected at the bottom. The feed is automatic. JDG(18)

MISCELLANEOUS (20)

Influence of the Quality of the Surface on the Corona Losses of Aluminum and Copper Cables. (Einfluss der Oberflächenbeschaffenheit von Aluminium und Kupferseilen auf die Koronaverluste.) SCHMITT & KRINES. *Electrotechnische Zeitschrift*, Vol. 51, Mar. 27, 1930, page 468–469.

Tests were made with old and new cables. It was found that the losses of old cables were always lower than those of new cables which is ascribed to the fact that the old cables have a smoother surface due to wear. The roughness of the new cables acts like points, which is more pronounced in the harder copper than in the soft aluminum. Ha(20)

Plastic Torsion—An Experimental Determination of Stress Distribution in a Bar which Has Been Twisted to the Limit of Plasticity. A. NADAI. *Preprint American Society of Mechanical Engineers*, Dec. 1–5, 1930, 15 pages.

The author compared the distribution of stress with the position of the thin layers of slip observed in the etched cross-sections of twisted steel bars. See *Metals & Alloys*, Vol. 1, May 1930, page 527. (20)

Developments in Steel Mill Lubrication. *Lubrication*, Vol. 16, Oct. 1930, pages 109–120.

This article considers the automatic handling of lubricants in the rolling mill. Operating conditions of gears and pinions, table roll drives, roll necks, the screw-down are considered in detail. Pressure lubricators are illustrated. (20)

Chemical Reactions in Flotation. ARTHUR F. TAGGART, T. C. TAYLOR & A. F. KNOLL (Columbia University). *Technical Publication* No. 312, *American Institute of Mining & Metallurgical Engineers*, 1930, 33 pages.

Flotation with soluble reagents is due to simple chemical reactions between reagents and compounds occurring on the surface of the particles affected. Experimental evidence to uphold this deduction. 37 references. JLG(20)

Scrap Zinc as a Precious Metal Precipitant. E. T. ELLIS. *Metal Industry* (London), Vol. 37, July 18, 1930, pages 53–54.

Zn scrap can be used in the precipitation of Au from waste solutions. It can also be used for treatment of double salt solutions, especially those containing gold cyanide with potassium cyanide. Scrap Zn is a precipitant for mixed gold effluents. Scrap Zn is also useful as a Pt precipitant. Introduction of scrap Zn into a solution containing soluble Ag will lead to decomposition of Ag in a metallic state. Recovery of Zn from effluents is accomplished very easily. VSP(20)

Qualifications and Duties of Open-Hearth Melter. MARTIN J. CONWAY (Lukens Steel Co.). *Iron Age*, Vol. 126, July 10, 1930, pages 78–79.

Two men are required to work an open-hearth furnace. Besides there must be a melter and a foreman. Outlines duties of each. VSP(20)

Reliability of Fusible Tin Boiler Plugs in Service. JOHN R. FREEMAN, JR., J. A. SCHERRER & S. J. ROSENBERG. *Metal Industry*, Vol. 36, May 9, 1930, pages 501–503; May 16, 1930, pages 532–533.

Condensed from Research Paper No. 129, U. S. Bureau of Standards. Gives results of tests conducted on 150 plugs. See *Metals & Alloys*, Vol. 1, March 1930, page 431. VSP(20)

Liege Congress. (Le congres de Liege.) LEON GUILLET. *Revue de Metallurgie*, Vol. 27, Aug. 1930, pages 393–397.

A brief outline of activities of the Sixth Congress of Mining, Metallurgy and Applied Geology held at Liege on June 22–28, 1930. JDG(20)

What Goes Out in Your Waste Cans? CHARLES O. HERB. *Machinery*, Vol. 36, July 1930, pages 841–847.

Describes the salvage work done by the by-products department of the A. C. Spark Plug Co., Flint, Michigan. Everything which will yield a profit is saved. This includes much metallic material: steel borings, turning chips, etc. Greater saving has been effected by keeping the scrap of different compositions separate as well as of different metals. Lead hammers are reclaimed. Solder dippings are remelted and cast into bars. Tool steels are separated by spark testing. RHP(20)

The Cross-sectional Resistance of the Oxide Film of Glow-Cathodes. (Zum Querwiderstand der Oxydschicht von Glühkathoden.) JULIUS KROCZEK & ERNST LUEBCKE. *Wissenschaftliche Veröffentlichungen aus dem Siemenskonzern*, Vol. 9, No. 2 (1930) pages 252–261.

The magnitude of the resistance which the electrons have to overcome in their emission from the core through the oxide film was determined by the cooling effect during emission of the cathode and the emission energy could be determined simultaneously by making up the energy balance. The theory of the problem is discussed in detail and the practical measurements are described. Ha(20)

The Aluminum Electrolytic Condenser. R. E. W. MADDISON (International Standard Electric Corp.). *London, Edinburgh & Dublin Philosophical Magazine & Journal of Science*, Vol. 8, July 1929, pages 29–55.

A list of 39 references is appended. Discusses the general theory of electrolytic condensers and gives the results of experimental work with aluminum electrolytic condenser. RHP(20)

Preparation of Metal Powders by Electrolysis of Fused Salts. Pt. 1. Ductile Uranium. F. H. DRIGGS & W. C. LILLIENDAHL. *Metal Industry* (London), Vol. 37, July 25, 1930, page 84.

Abstract of paper read before the American Chemical Society in Atlanta, April 7–11, 1930. VSP(20)

Calculation of the Temperature Course in Heating Processes. (Zur Berechnung des Zeitlichen und Oertlichen Temperaturverlaufes beim Glühvorgang.) A. SCHACK. *Stahl und Eisen*, Vol. 50, Sept. 11, 1930, pages 1289–1297.

Report 142 of the Heat Committee of the Verein deutscher Eisenhüttenleute. The characteristics of uniform and non-uniform heat flow and temperature conductivity are described as well as the present known practical solutions of the equation of non-uniform heat flow are given. The heat flow in bodies of different shape is calculated for 2 different cases, namely, for a sudden change of temperature of the surface and for a body which is suddenly subjected in a heat transferring medium to a temperature differing from that of the body. The temperature of the heat transferring medium is kept constant in this case. The soaking is in reverse proportion to the first power of the diameter of bodies which have excellent soaking properties due to a high temperature conductivity and a small thickness of the heated pieces. The soaking decreases proportional to the square of thickness in bodies with poor soaking properties. (Low heat conductivity or large thickness.) Diagrams are drawn and interpolated for the calculation of the temperature course in balls, cylinders and plates according to the calculation by Williamson, Adams and Groeber. The cooling conditions in a shaft 1 m. in diameter and 20 m. long, are calculated when cooled in air. A new approximate calculation method is developed for the heating of a 0.3 m. thick plate from one side only. A supposed heat transfer number and a suitable temperature of heating medium must be chosen in this case. GN(20)

The Effects of Chromium-Nickel Heating Wires on Ceramic Supports. (Ueber die Einwirkung von Chromnickel-Heizdrähten auf keramische Wicklungsträger.) E. ALBERS-SCHOENBERG & M. BICHOWSKY. *Elektrotechnische Zeitschrift*, Vol. 50, Dec. 19, 1929, pages 1837–1840.

The well-known destruction of heating wires and their ceramic supports is studied by intentional production of unfavorable operating conditions and observation of the fusing phenomena. The occurrence of colored deposits and melting-spots are explained chemically and electrically. This leads to some surprising facts, i. e., the purely thermal formation of chromic acid anhydride on the surface of red-hot chromium-nickel wire and the movement of oxide fog in an electric field. The authors conclude that it will hardly be possible to always find one suitable to ceramic material; cases have to be studied individually and the shape of the ceramic support is of eminent importance for the life of the combined unit. Ha(20)

On the Attack of Metals by Insects. (Uber den Angriff von Metallen durch Insekten.) O. BAUER & O. VOLLENBRUCK (Kaiser Wilhelm Institut für Metallforschung, Berlin-Dahlem). *Zeitschrift für Metallkunde*, Vol. 22, July 1930, pages 230–233, 7 references; *Mitteilungen der deutschen Materialprüfungsanstalten*, Vol. 13, 1930, pages 3–7.

The proof was furnished that certain species of beetles are able to attack metals. The attack is of a mechanical nature. By hard and sharp organs the beetles gnaw and drill themselves through the metal by tearing off small chips. The harder the metal the more difficult the work for the insect. For both species investigated, *Dermestes peruvianus* and *Dermestes lardirius*, aluminum and zinc seem already to offer too large a resistance, whereas lead and, with greater difficulty, tin are destroyed. EF(20)

On the Self-Ignition of Blast Furnace Dust. (Ueber selbstentzündlichen Gichtstaub.) H. ECKSTEIN. *Stahl und Eisen*, Vol. 50, Sept. 4, 1930, page 1270.

The author summarizes observations of self-igniting blast furnace dust, made in the Röchling Steel mills at Völklingen-Saar district. Whereas self-igniting blast furnace dust is generally traced to the presence of zinc dust, no clear relationship between self-ignition and zinc dust could be stated; though zinc was also in this case found to be the reason for self-ignition. It is possible that the presence of metallic iron and manganese accelerated the self-ignition. GN(20)

The Occurrence of Beryllium. (Das Vorkommen von Beryllium.) M. HOSENFELD. *Wissenschaftliche Veröffentlichungen aus dem Siemens-Konzern*, Vol. 8, No. 1 (1929) pages 21–25.

Brief outline with 25 references giving location of beryl. (20)

Oxidation of Mercury Vapor on Incandescent Platinum. (Ueber die Oxidation des Quecksilberdampfes am glühenden Platin.) Y. OKAYAMA. *Zeitschrift für physikalische Chemie*, Vol. 6, Feb. 1930, pages 355–367.

The oxidation velocity of Hg-vapor in incandescent Pt was studied at low pressures. The oxidation speed is nearly independent of the vapor pressure of the Hg but increases with rising oxygen pressure according to the formula:

$$-\frac{\Delta n}{\Delta z} = \frac{\sqrt{p}}{a + b\sqrt{p}}.$$

EF(20)

Thermochemistry of Iron, Manganese and Nickel. (Beiträge zur Thermochemie des Eisens, Mangans und Nickels.) WALTHER A. ROTH. *Stahl und Eisen*, Vol. 49, Dec. 5, 1929, pages 1763–1765.

Abstract of a paper presented before the Chemists' Committee of the Verein deutscher Eisenhüttenleute. See *Metals & Alloys*, Vol. 1, Mar. 1930, page 431. (20)

The Production of Very Pure Mercury. (Die Herstellung sehr reinen Quecksilbers.) H. VON STEINWEHR & A. SCHULZE. *Zeitschrift für Instrumentenkunde*, Vol. 49, Nov. 1929, pages 566–567.

The authors describe the methods for the purification of mercury for scientific purposes as applied in the Physikalisch-Technische Reichsanstalt-Berlin. After agitating with diluted nitric acid and benzene or alcohol, the metal is filtered through leather or a porcelain filter and then submitted to distillation according to the method of Hulett which was modified. Electrolytic purification is superfluous whereas the storage causes trouble. Preservation in evacuated gas bottles proved to be the best method. EF(20)

Chrome Plating and Anodic Oxidation. *Metallurgia*, Vol. 2, May 1930, page 3.

An investigation by H. M. Medical Inspectors of Factories of 200 persons engaged in chromium plating and anodic oxidation processes proved that these processes are dangerous. In more than half of the workers the mucous membrane of the nose had been affected by the spray generated. The risk can only be eliminated by efficient exhaust ventilation. JLG(20)

The Rarer Metals in Glass. *Vancoram Review*, Vol. 1, Oct. 1930, pages 149–152.

The application of the rarer metals in glass is briefly discussed. (20)

Electrically-Generated Hydrogen Serves as Descaling Agent. *Iron Trade Review*, Vol. 86, March 27, 1930, page 67.

It is claimed that the Bullard-Dunn process of cleaning metal surfaces by the action of cathodic hydrogen removes only scale, oxide and foreign matter, without attacking the original metal regardless of the time of immersion. MS(20)

The Plastic State of Metals. A. NADAI. *Metal Industry* (London), Vol. 36, April 11, 1930, pages 405–406.

Steel Plant Lubrication Problems. W. A. JAMES. (Lackawanna Plant—Bethlehem Steel Co.) *Iron Age*, Vol. 125, May 15, 1930, pages 1455–1456; *Iron & Coal Trades Review*, Vol. 121, July 25, 1930, page 120.

Includes discussion. Abstract of paper before the American Iron and Steel Institute, May 9. See *Metals & Alloys*, Oct. 1930, page 804. RHP+VSP(20)

Contributions to the Thermo Chemistry of Iron. (Beiträge zur Thermochemie des Eisens.) W. A. ROTH, H. UMBACH & P. CHALL. *Archiv für Eisenhüttenwesen*, Vol. 4, Aug. 1930, pages 87–93; *Stahl und Eisen*, Vol. 50, Sept. 18, 1930, pages 1331–1332.

Report No. 78 of the Chemical Committee of the Verein deutscher Eisenhüttenleute. The heat of formation and heat of transformation of some iron compounds which have been determined in a calorimeter in a former investigation (*Archiv für Eisenhüttenwesen*, Vol. 3, 1929, pages 339–346) have been checked by dissolving these compounds in hydrochloric acid. The method is described in detail; the difficulties in dissolving iron ores are discussed and the necessary correction values are given. The heat of formation of FeO was determined as 64.2 kg. cal. ± 0.1 kg. cal., the heat of formation of magnetite from Fe_2O_3 and FeO as 7.0 kg.cal. the heat of formation of fayalite as 8.1 kg. cal. and the chlorination heat of Fe_2O_3 as 7.4 kg. cal. GN(20)

Sizes and Tolerances for Metal Fits. C. R. REIMAN. *Preprint American Society of Mechanical Engineers*, Dec. 1–5, 1930, 10 pages.

This paper discusses comparisons of metal fits. The matter of working fits being left in many plants largely to the opinion and ability of the workman, the need of standardization in consequence asserts itself as organizations are entitled to records of these matters. The comparisons of the practice of other standards and the analysis that influences the conclusions are given in a simple way. Simplification for better understanding is aimed at, and the need for a standard common practice throughout the industry is recognized. Controlling influences are considered, and various features for which advantages are claimed are stressed. The use of the basic size to under hole system, and the basic shaft are discussed. Different kinds of fits are compared, and the reasons for differentiating between straight shafts and turned studs are given. (20)

Laws Governing the Natural Occurrence of Metals. (Gesetzmässigkeiten im natürlichen Vorkommen der Metalle.) G. BERG. *Metallwirtschaft*, Vol. 9, Jan. 3, 1930, pages 1–7.

Includes 10 references. Discusses the relation between geological formations and the physical chemistry of minerals and gives reasons why certain elements are usually found together in the same mineral groups. Discusses the effect of freezing points, boiling points and vapor pressure of different constituents of a molten mass, change of solid solubility with temperature. Metallography, X-rays and atomic structure are made use of in the study. The exterior of the earth is composed principally of silicates, the center of iron and nickel, with an intermediate layer consisting probably of sulphides. Isomorphism and solubility depend on atomic volume. Effect of primary and secondary crystallization. Illustrations are given of Ni, Co, Cu, Fe, Mn, Pt, Pd, Au and Sn. CEM(20)

FOUNDRY PRACTICE & APPLIANCES (22)

Continuous Electric Melting and Other Gray Iron Practice. *Iron Age*, Vol. 126, July 10, 1930, pages 87–88.

A topic of discussion at one of the sessions at Cleveland before the American Foundrymen's Association in May. An outline of practices and results at the Beach Foundry, Ltd., Ottawa, Canada was given in a paper by N. L. Turner. Includes the cost of electric Fe per ton and analysis of stove plate gray Fe. A method of briquetting cast Fe borings to a density of 70 to 85%, without use of binder was described by Harry Rayner. Other problems taken up were cupola operation, foundry nomenclature and alloy Fe and heat treatment. VSP(22)

Incorrect Weighting of Moulds. "VALLISHE." *Foundry Trade Journal*, Vol. 42, May 8, 1930, pages 345–346.

Study of weighting and clamping of molds includes several factors: (1) Type of castings and sizes; (2) size and weight of box, (3) area and weight of sand when rammed, (4) head pressure, (5) number of runners, and (6) buoyancy. Determination of lifting pressure on a core. Contains table giving pressure on round or square cores. VSP(22)

Methods of Moulding Castings for Stoves, Heating Apparatus and Various Builders' Castings. H. MAGDELENAT. *Foundry Trade Journal*, Vol. 43, July 10, 1930, pages 24–27.

French exchange paper presented before the Institute of British Foundrymen. Description is given of methods of molding a pedestal stove, cooking range parts, skylight and a sink. The Rosieres-Bachon patent continuous molding machine, constitutes a complete molding shop. Used for repetitive production of flat and slight relief castings. The chief advantages of this machine are: (1) ramming of the sand by multiple rollers; (2) method of effecting the movement of strippers and the conveyor trolley in an endless circuit. VSP(22)

MOORE RAPID 'LECTROMELT FURNACES

'Lectromelt

Recent 500 lb. per hour 'LECTROMELT furnace installation for special alloy work.

'LECTROMELT furnaces offer the rapid and economic means of producing stronger, denser, cleaner and closer grained irons and steels under constant analytical and temperature control.

Over 40 users making corrosion and heat resistant irons and steels.

WRITE FOR PARTICULARS

Pittsburgh Electric Furnace Corporation
Pittsburgh, Penna.

The Founding of Bronze. (La Fonderie de Bronze.) L. THIBAUT. *Fonderie Moderne*, Vol. 23, Oct. 25, 1929, pages 501–503.
The historical development of bronzes is outlined. Special attention is called to the value of nickel-containing bronzes. (22)

Iron and Steel Foundry Practice. BEN SHAW. *Metallurgia*, Vol. 2, Aug. 1930, pages 135–136, 155; Vol. 3, Nov. 1930, pages 20–22, 34.
Discusses reasons why steel is more difficult to cast than iron. Briefly discusses the influence of various alloying elements on steel castings. Molybdenum is particularily advantageous as an alloying element. JLG(22)

Advantages of Electrical Melting Furnaces. FRED W. FRIESE. *Metallurgia*, Vol. 2, Aug. 1930, page 128.
In Brazil it is more economical to melt copper alloys in an electric furnace than in a crucible furnace. Some costs are given. JLG(22)

Synthetic Cast Iron Made in Electric Furnace. NATHUSIUS. *Foundry Trade Journal*, Vol. 42, June 5, 1930, page 423.
Process is based on the fact that carburization of Fe takes time and cannot be accelerated by increasing the supply of electricity. Describes a furnace being used by Brown-Boveri. Gives a table showing mechanical properties of some melts. See *Metals & Alloys*, Vol. 1, Aug. 1930, page 683. VSP(22)

Some Recent Developments in German Foundry Practice. S. G. WERNER. *Foundry Trade Journal*, Vol. 42, April 10, 1930, pages 272–276.
Paper read before London section of the Institute of British Foundrymen. Problems which have been dealt with are: the behavior of cast iron and steel castings at high temperatures, growth of cast iron, machinability of steel and cast iron and various others. The Heinrich Lanz. A. G. of Mannheim have done pioneer work on pearlitic iron. To overcome difficulties arising when producing high temperatures the oil fired Wüst furnace was developed. Another furnace which has been quite a success is the Brackelsberg furnace. Other developments taken up are sand research, fettling and time studies. VSP(22)

The Future of the Side-Blown Converter in the Steel Industry. J. DESCHAMPS. *Foundry Trade Journal*, Vol. 43, July 3, 1930, page 14.
From a paper read before the Institute of British Foundrymen. The question of the future of the side-blown converter is of interest to steel founders. Object is to show why the number of these furnaces in steel foundries is likely to increase in the future in view of the advantages this process presents. Converter process has the advantage over the open-hearth and electric process owing to greater flexibility. For a given temperature side-blown converter steel has greater fluidity. Elimination of occluded gases and silicates is easier. Although cheaper than electric steel it is costlier than open-hearth. VSP(22)

Casts Pipe Centrifugally in Sand Molds. PAT DWYER. *Foundry*, Vol. 58, July 1, 1930, pages 98–102.
This is the 4th of a series of articles. Describes method employed by the American Cast Iron Pipe Co., Birmingham, Ala. The most spectacular achievement has been the introduction and development of the monocast centrifugal process for making cast iron pipe. Ovens are heated with by-product gas. Pipes of 4, 6, 8, 10 and 12 in. in 16 ft. lengths are produced. Green sand molds are used. Cupolas are charged mechanically. VSP(22)

Superheating Cast Iron. P. BARDENHEUER & K. L. ZEYEN. *Foundry Trade Journal*, Vol. 42, June 5, 1930, pages 422–423.

Abstract of paper read before the Institute of Metals, Sept. 10, 1930. See *Metals & Alloys*, Vol. 1, Nov. 1930, page 855. LFM(22)

The Fundamentals of Brass Foundry Practice. R. R. CLARKE. *Metal Industry* (London), Vol. 36, June 13, 1930, pages 633–634.
Oxidation and gasification is very prominent in Cu. To overcome this, and where electrical requirements are not high 2% Zn and trace of P is added. Other substances added are Si and Mg. Charcoal is the most reliable aid in Cu manipulation. In pouring, hot metal is better than cold. Difficulties encountered in Cu molding: (1) high and local shrinkage; (2) obtaining clean-metal. Cu has a tendency to congeal in its centers of bulk. Often Cu riser top surface shows no shrinkage, while underneath heavy shrinkage is in evidence. Gating point of Cu should be where metal will be delivered with least commotion and mold punishment. Mechanical agitation works up and releases dross. VSP(22)

Casting Monel Metals. W. J. REARDON. *Brass World*, Vol. 25, Dec. 1929, page 291.
Some practical information for making monel metal castings. WHB(22)

Malleable Cast Iron. G. R. SHOTTON & G. H. HALL. *Foundry Trade Journal*, Vol. 42, May 29, 1930, pages 399–404.
Read before Birmingham Junior Section Institute of British Foundrymen. Malleable castings were first produced in Europe in 1722 by Réaumur. The black-heart-type malleable cast Fe was discovered in America by Seth Boyden. Difference between white-heart and black-heart type is that the former obtains its malleability from oxidation of C, and the latter by graphitization of C. Freezing of white Fe. The analysis of white-heart cast Fe is: Total C 3.20–3.80, Si 0.45–0.75, Mn 0.30–0.40, S 0.20–0.35 and P below 0.10%. The analysis of black-heart type of white cast Fe is: Total C. 2.30–2.60, Si 0.75–0.90, Mn 0.25–0.35, S 0.03–0.06 and P below 0.20% Effects of common elements. The effect of Si is to favor graphitization. S has a retarding effect on graphitization, and is the controlling factor between varieties of malleable cast Fe. Mn should be present in the atomic ratio 1.72 times the % of S. In black-heart type Fe it should be about 0.2–0.25%. P can be as high as 0.2% but usually above 0.1% in white-heart Fe, and 0.15% in black-heart Fe. The control of melting operations must be rigid. In production of malleable Fe the oxidation is kept as low as possible. Malleable foundry differs in few respects from gray Fe foundry. Before annealing castings are freed from sand, they are also fettled, and all gates broken off. They are packed with ore or slag to keep from warping due to the high temperature. Black-heart-type malleable is much superior to white-heart in every respect. Its physical properties can be altered to serve many diverse needs. VSP(22)

The Founding of Bronze Gear Blanks. FRANCIS W. ROWE. *Foundry Trade Journal*, Vol. 42, June 19, 1930, pages 449–450, 464; June 26, 1930, pages 469–470.
Paper presented before the Institute of British Foundrymen. The value of bronze for gear blanks is due chiefly to its low coefficient of friction when working against hardened steel. The material used being usually a tin phosphor-bronze with from 10.5 to 13% Sn and 0.1 to 0.5% P. The hard particles of α-δ eutectoid give the resistance to wear and hardness. The soft Cu-Sn solid solution give resiliency. Close control of raw material is essential. Melting as practiced by author is done in a battery of coke fired reverberatory furnaces supplemented by pit-fire furnaces and induced-draft tilting furnaces for special heats. Gear blanks are usually cast centrifugally. Sand casting, due to slow rate of solidification has a low density. Casting with a ring chill is an improvement over sand casting. It has however several drawbacks. Gives advantages of centrifugal casting and method of procedure. Discusses also other types of gear castings. VSP(22)

On the Influence of Colloidal Ferric Hydroxide upon the Properties of Moulding Sand. E. TAKAHASI. *Kinzoku no Kenkyu*, Oct. 1930, pages 552–562.
Molding sand containing 10% water was found to have maximum strength. The effect of ammonia (or alkalies) upon the strength of the molding sand was not noticeable. But the effect of hydrochloric acid was very powerful and the strength increased by about 25% at 0.02N. The addition of colloidal ferric hydroxide increased the gas permeability according to ramming condition. Synthetic molding sand was made and tested as follows: Silica sand of the size 0.1–0.25 mm. was washed with hydrochloric acid. This sand has a negative charge when it is in contact with water. Colloidal ferric hydroxide solution (ferric hydroxide solution has positive charge) was filtered by the sand layer. And thus the sand was coated by ferric hydroxide film. One part of refined clay powder was ground with 3 parts of dried ferric hydroxide. One part of this mixed powder was ground with 10 parts of clay powder. Synthetic molding sand was then made with the sand and 10% of the clay mixture. The strength of it was about 50% greater than the molding sand which consists of silica sand and clay, both untreated with ferric hydroxide. The gas permeability of the former was a little less than the latter up to 17% of water content, but is greater above it. KT(22)

FURNACES & FUELS (23)

The Economics of Heat Treating. ROBERT M. KEENEY (Connecticut Light & Power Co.). *Transactions American Society for Steel Treating*, Vol. 17, May 1930, pages 615–630.
A paper presented before the New York Chapter of the Society, Dec. 1929. The selection of fuel for a heat treating application is an economic problem involving not only the B.t.u. but also the effect of the use of the various fuels on the amount and quality of the work produced. The author discusses conditions local to the Connecticut valley as applying various fuels to annealing, carburizing and hardening of steel and the annealing of non-ferrous metals. Each heat treatment has its best fuel for a given locality and condition, and the author warns equipment salesmen and industrial executives against a too enthusiastic reception of any one fuel as a universal heating medium. WLC(23)

Heat Treatment Furnaces. A. G. LOBLEY. *Automobile Engineer*, Vol. 20, March 1930, pages 110–111.
Abstract of a paper recently presented to the Coventry Branch of the Institution of Production Engineers. Two primary advantages of the electric furnace are exactitude of control, and flexibility. These are especially important in the automotive industry. Depending on the operation. Electric heating may in some cases be as cheap as coal and cheaper than gas. Nickel chromium may be used up to a temperature of 1100° C. This alloy is almost universally used to-day by electric furnace makers. Discusses electric furnace construction practice. RHP(23)

Possibilities of Electric Furnace. (Les possibilities du four electrique.) PAUL MARTHOUREY. *Journal du Four electrique*, Vol. 39, July 1930, pages 247–248.
Generalities. JDG(23)

Wider Use of the Soderberg Self-Baking Electrode. JAMES SILBERSTEIN. *Iron Age*, Vol. 126, July 10, 1930, page 94.
First self-baking electrode was installed in Norway in 1919. Soderberg electrode is molded to shape by ramming soft preheated C paste into a cylindrical sheet steel container. When electrode is installed, furnace must be run with coke for first 8 or 10 hours and at low electrical load. No ore should be charged against electrode. Savings by Soderberg electrode are due to absence of butts and less air corrosion of electrode. VSP(23)

The Selection of Fuels for Heating Coke Ovens. H. L. CAMPBELL. *Foundry Trade Journal*, Vol. 43, July 3, 1930, page 6.
Abstract of article from Industrial Gas. Owing to difficulty of controlling temperatures in oven fired with coal, this fuel is not adapted to heating core ovens. Powdered coal burns at very high temperatures; provisions must be made for lowering the temperature before they enter core ovens. Disadvantage of using coke is the difficulty of controlling the temperature and atmosphere throughout interior of core ovens. Cites also disadvantages of fuel oil and electric heating. Industrial gas is suited to heating at temperatures used for baking cores. Gives advantages of industral gas. VSP(23)

Control of Mixed-Gas Furnaces. KARL A. MAYR. *Iron Age*, Vol. 126, July 24, 1930, pages 225–228.
Chiefly a translation of Karl Loebbecke's article in *Feuerungstechnik*, Vol. 17. Two methods of burning gas in one furnace: Gases may be mixed before entering furnace, or individual gases may be fed by separate burners or group of burners. Efficient operation requires exact air proportions. The Arca multiple-gas control secures automatically the supply of combustion air by the operation of a single damper for 2 or 3 different fuels used in one combustion apparatus. Gives detailed description of operation of the apparatus. To adjust proper amount of combustion air, the amount of gas supplied is measured, and also the amount of gas to be fired. Gives calculation of air requirements. VSP(23)

Sklenar Midget Furnace. *Foundry Trade Journal*, Vol. 42, May 1, 1930, page 322.
Describes furnace developed by the British Reverberatory Furnaces, Ltd. It is a 300 lb. brass capacity, which eliminates crucibles and tap-holes. It preheats charges, recuperates waste gases and is mechanically emptied by tilting. Oil firing is standard but coke fired furnaces are available. Gives experimental data. VSP(23)

The Rotatory Furnace for Iron Founding. *Metallurgist*, Aug. 1930, pages 119–120.
A general discussion of the paper by Auguste Le Thomas in the May issue of the *Revue de Metallurgie* in which the author compares the rotating cylindrical furnace for melting cast iron for foundry purposes with the old cupola type. See *Metals & Alloys*, Vol. 1, Nov. 1930, page 856. VVK(23)

Industrial Electric Furnaces. *Electrical Review*, Vol. 105, Oct. 18, 1929, pages 674–676; Nov. 1, 1929, pages 773–774.
Illustrations and descriptions of the "Birlec" rotating annular-hearth, box-type, and pusher-type furnaces built by the Birmingham Electric Furnaces; Metropolitan-Vickers Electrical Co., induction furnace; double-ended furnace for precious metals and high-efficiency resistance furnaces, built by Electric Furnace Co., "Lecfur" melting-pot and B.E.S. 3 and C.C.8 furnaces, built by Leeds Electrical Constructional Co., and a carburizing furnace built by Wild-Barfield Electric Furnaces. MS(23)

Coreless Induction Furnaces. (Les fours à induction sans circuit ferromagnètique.) M. GLIKSMAN. *Revue Generale de e'Electriciti*, Vol. 26, Sept. 7, 1929, pages 361–370.
Mathematical study of the influence of the frequency of the supply current on efficiency. Concludes that high frequencies are of real advantage in the case of furnaces of small capacities, such as laboratory furnaces where heating takes place by indirect induction, i. e., in a graphite crucible and not in the mass of the charge itself. For metallurgical operations on an industrial scale, commercial frequencies are suitable. MS(23)

Normalizer Improves Sheet Quality. *Iron Trade Review*, Vol. 86, March 13, 1930, page 58.

Central Alloy Steel Corp. has installed a walking-beam type continuous normalizing furnace. Unit is 130 ft. long, furnace proper being 100 ft. long, with an effective interior width of 108 in. Gross capacity is 8 tons/hr. consumes 1300 cu. ft. of natural gas per gross ton of product. It will operate satisfactorily at any temperature up to 1850° F. Work passes through furnace at 2½-10 ft. per min. MS(23)

The Utilization of Waste Heat in the Steel Industry. C. W. E. CLARKE. *Iron Age*, Vol. 125, June 5, 1930, page 1681–1684

From paper before the American Iron & Steel Institute, May 1930. See *Metals & Alloys*, Vol. 1, Nov. 1930, page 855. VSP(23)

The Grünewald Bright Annealing Process. (Das Grünewald-Blankglühverfahren.) R. W. MÜLLER. *Metallwirtschaft*, Vol. 9, June 20, 1930, pages 525–527.

An electric annealing furnace is described in which the work is heated in a pot made air-tight with a lid fitted with a rubber gasket which is water cooled. The pot is supported from the top of the furnace and the work is suspended from the lid. As the pot serves only to exclude air and does not support any weight it can be made from thin sheet material instead of a heavy casting. Advantages are quicker heating and lower power consumption. The lid is fitted with a valve and during heating most of the air is driven out and the oil, which usually covers the work, forms a non-oxidizing atmosphere. After heating, the pot can be removed and another placed in the same furnace. During cooling a vacuum forms in the pot. The process can be used for the bright annealing of any metals up to 750° C., especially between rolling and drawing operations. CEM(23)

Orientation of metallurgical coke industry in Central Europe. (Orientation actuelle de l'industrie du coke metallurgique dans l'Europe Centrale.) CH. BERTHELOT. *Revue de Metallurgie*, Vol. 27, Sept. 1930, pages 486–500.

Points out the lagging of France in the development of efficient coking plants following Central European lines. Enumerates the conditions leading to efficiency, both in the construction of ovens and coking methods as already adopted in Germany and Czechoslovakia. Figures of performance and of the relation between design and efficiency are given. Considerable attention is paid to the influence of the peculiarities and faults in design. JDG(23)

A New Universal High-Vacuum Furnace. (Eine neue Universal-Hochvakuum-Ofenanlage.) *Electrotechnische Zeitung*, Vol. 51, Aug. 7, 1930, pages 1146–1147.

Short description of a furnace for laboratory and industrial use made by the Elektro-Schaltwerk A.-G., Goettingen, Germany. The heating elements are of molybdenum wire, the furnace is water-cooled and can be tilted, and has three exchangeable covers. It takes 25 minutes to obtain a vacuum of 40×10^{-4} mm. Hg; 3 pounds of copper can be melted in 41 minutes with an energy consumption of 1.29 kwh. Ha(23)

Practical and Theoretical Heat Balance for Rotary Forging Furnaces. THEODORE F. SCHILLING (Mahr Manufacturing Co.). *Transactions American Society for Steel Treating*, Vol. 18, Aug. 1930, pages 235–249.

An analysis and comparison of 3 sizes of rotary forging furnaces using 4 different fuels are made, giving theoretical and actual values. There is a discussion of production rates of such furnaces, the selection and operation of them. WLC(23)

Artificial Atmospheres in Electric Furnaces. A. J. STRAIN. *Canadian Chemistry & Metallurgy*, Vol. 14, Oct. 1930, pages 290–292.

A process has been developed which involves the complete or partial thermal decomposition of hydrocarbons with or without steam, to produce mixtures having carbon monoxide, hydrogen and carbon dioxide as the main constituents. The relative quantities of gases in the mixture will depend upon: (1) the hydrocarbon being treated; (2) the temperature to which it is heated, and (3) the amount of steam used. The choice of raw material depends upon: (1) its availability; (2) the use to which the electrolene is to be put; and (3) its effects upon the final cost of the electrolene. The raw materials necessary for the production of electrolene are: gas, steam and electrical energy. Twelve advantages claimed for the electrolene producer over all other commercial apparatus are listed. Several tables and illustrations are included. WHB(23)

Overcoming the Smoking Habit in Oil-Fired Furnaces. F. J. GUTSCH (Southern Pacific Co.). *American Machinist*, Vol. 72, March 6, 1930, pages 417–418.

Illustrates and describes an oil-fired furnace developed by the Southern Pacific Company. Heating work may be begun within ten minutes after the oil has been ignited. Burns all of the oil and leaves no carbon deposit. In operation, the oil drops on to the sharp blast of air which breaks it up into small particles. The super heater thoroughly vaporizes the oil so the combustion is almost perfect. No smoke after the furnace is warmed up. RHP(23)

Open Hearth Control. H. V. FLAGG. *Iron & Steel Engineer*, Vol. 7, Oct. 1930, pages 480–481; discussion, pages 487–489.

Four essential factors influencing fuel economy in the open hearth operation are: (1) the fuel to be used; (2) furnace design; (3) the training of the operators; and (4) the equipment. WHB(23)

Development in Fuel Economy at Skinningrove. FRANK BAINBRIDGE. *Iron & Coal Trades Review*, Vol. 120, May 2, 1930, pages 709–711.

Abridged copy of a paper before the Iron and Steel Institute, May 1930. See *Metals & Alloys*, Vol. 1, Sept. 1930, page 744. RHP(23)

Power Production in the Steel Industry. W. E. CLARKE. *Iron & Coal Trades Review*, Vol. 120, June 27, 1930, pages 1021–1022.

Discusses the use of blast furnace gas to heat boilers and its use in underfiring. Also arrangement of burners in the furnace. Coke and coke breeze can be burned in powdered form. Waste heat boilers are of doubtful value in modern plant. Power units have greatly increased in capacity. RHP(23)

Industrial Electric Heating. XII. The Three-Phase Arc Furnace. N. R. STANSEL. *General Electric Review*, Vol. 33, Feb. 1930, pages 123–129.

This paper is one of a long series and deals with three-phase furnaces in steel making. These furnaces range from 500–5000 kv.-amp. The largest in use has 2 sets of electrodes, each supplied with a 10,000 kv.-amp. transformer. The furnace construction and complete equipment for this type are described in detail, pointing out the differences in the acid and the basic processes. The temperature limit of the furnace is the melting point of the refractory (1700° C. for silica brick). The energy distribution for the average acid melting practice is: useful 67%, heat flow through enclosures 16, heat flow through openings 7, escaping gases 5, cooling water loss 5%. The average percentage values of a number of heat balances of a 15-ton basic furnace are tabulated. Characteristics of the arc furnace circuit are discussed and graphs show that it is undesirable to operate with maximum power input because of consequent low electrical efficiency and power factor. The most desirable current in the arc depends in each case upon the characteristics of the arcs and of the charge and must be determined by trial for each furnace. Safety, electrical insulation and the possible introduction of nitrogen into the steel have been limiting factors as regards the voltage for these circuits. Comparative values of kw. input and amperes for melting periods of two hours, 1½ hrs., and 1 hr. are given. WHB(23)

Electric Furnaces with Basket Charging. (Fours electriques a chargement par paniers.) *Journal du Four electrique*, Vol. 39, August 1930, pages 292–294.

The roof and electrode holders of arc electric furnaces are made movable so that both can be removed from the furnace easily and without disconnecting either leads or water connections. The charge is placed in a basket with a removable bottom. A crane places it in the furnace from which the roof is removed. The bottom is disconnected and left in the furnace while the basket is removed. Total operation including the removal of the roof and full charging does not take more than 5 minutes. Many advantages are claimed. Two 6 ton furnaces with this arrangement averaged an extra heat a day and decrease of current consumption by 50 kwh./ton. JDG(23)

A Small Furnace for Melting Aluminum and Its Alloys. (Kleiner Flammofen zum Schmelzen von Aluminium und Aluminiumlegierungen.) ROBERT J. ANDERSON. *Metallwirtschaft*, Vol. 9, Oct. 31, 1930, pages 899–901.

Contains 2 references. An open-hearth furnace of 1 to 2½ ton capacity has the advantages of simple construction, quick melting and thermal efficiency. A 1 ton furnace is described in detail and dimensions of its parts are given. It can be oil or gas fired. The process of melting is described. It takes ½ hour to heat the furnace to 760 ° C. and 2 hours to bring a 1 ton charge of Al up to heat if the furnace is preheated. CEM(23)

Heat Losses and Durability of the Roof of Open Hearth Furnaces. (Wärmeverluste und Haltbarkeit des Siemens-Martingewölbes während einer Ofenreise.) A. SCHLÜTER. *Stahl und Eisen*, Vol. 50, Oct. 2, 1930, pages 1393–1397. 3 references.

Report 192 of the Steel Mill Committee of the Verein deutscher Eisenhüttenleute. Including discussion. In measuring the surface temperatures of the roof of an open hearth furnace over a long run it was found that the heat losses increase above 3 times, in percentage, of the total heat consumption of the furnace from 3.2 to 8.5%. From these measurements the actual thickness of the roof was calculated which shows that there is a decrease of the roof thickness proportional to the time. The normal wear of the roof does not depend upon the thickness of the brick, but rather depends on the velocity which which the bricks are transformed to slag. The consequences of local superheating increase with increasing brick thickness. The quality of the bricks has its bearing on the slagging. GN(24)

GASES IN METALS (25)

The Absorption of Gases by Metals. A. SIEVERTS. *Metallurgist*, Nov. 1929, pages 168–172.

A critical review of the present knowledge of the solution of gases in liquid and solid metals. See *Metals & Alloys*, July 1929, page 26. (25)

Nitrogen in Technical Iron. WERNER KÖSTER. *Iron & Coal Trades Review*, Vol. 120, June 6, 1930, page 920.

Abstract of a paper from *Archiv für Eisenhüttenwesen*, April 1930, pages 637–658. See *Metals & Alloys*, Vol. 1, Sept. 1930, page 745. RHP(25)

Nitrogen in Technical Iron. (Zur Frage des Stickstoffs im technischen Eisen.) Part III. The Precipitation of Nitrogen and Carbon in the α-Solid Solution, as an Example of the Decomposition of a Twice Supersaturated Solid Solution. (Teil III. Die Ausscheidung von Stickstoff und Kohlenstoff aus dem α-Eisen als Beispiel des Zerfalles einer doppelt übersättigten festen Lösung.) W. KÖSTER. *Archiv für Eisenhüttenwesen*, Vol. 4, Sept. 1930, pages 145–150; *Stahl und Eisen*, Vol. 50, Oct. 2, 1930, pages 1401–1402.

Report 165 of the Material Committee of the Verein deutscher Eisenhüttenleute. The influence of the super-saturation of α-iron with nitrogen and carbon on the segregation of nitrogen was studied by measuring the changes of the coercive force. The annealing isotherms of a nitrogen bearing Thomas-steel, which has been quenched from a temperature below A_1, have been taken. It follows that, carbon only has its influence on the magnetic properties at room temperature, whereas the influence of nitrogen predominates at temperatures of 110° to 150° C., but the carbon predominates again at temperatures above 150° C. A strong retarding of the increase of the coercive force can be observed at 110° C. in the quenched steel, compared with a slowly cooled steel, which points to a slackening of the nitrogen precipitation caused by the carbon present. Later the coercive force increases again due to the precipitation of carbon. The increase of the coercive force due to the nitrogen precipitation decreases with increasing quenching temperature, i. e., the higher the amount of carbon in solid solution. The amount of precipitated nitrogen decreases with increasing amount of carbon in the solid solution, a constant nitrogen content provided. Thus it follows that the isothermal precipitation of an element is very much influenced by the presence of another element which is simultaneously in solution. The importance of these findings on the elucidating of the aging process of duralumin is pointed out. GN(25)

Relation of Nitrogen to Blue Heat Phenomena in Iron and Dispersion Hardening in the System Iron–Nitrogen. R. S. DEAN, R. O. DAY & J. L. GREGG (Western Electric Co.). *American Institute of Mining & Metallurgical Engineers, Transactions, Iron and Steel Division* (1929) pages 446–453.

Nitrogen increases or causes "blue-brittleness." Fe-N alloys are subject to precipitation hardening. Contains 3 references. JLG(25)

The Occlusion of Hydrogen and Nitrogen by Pure Iron and Some Other Metals. DR. ERICH MARTIN. *Metals & Alloys*, Vol. 1, Nov. 6, 1930, pages 831–835.

A correlated abstract. Measurements were made by placing the metal samples in a fused silica vessel designed to permit evacuation and introduction of a desired atmosphere. The vessel was also connected with a gas analyzer. Observations indicate that argon is not occluded by any metal, hence a series of observations were made with this gas and comparison curves are shown for H_2 and N_2 both in the presence and the absence of metal. The occlusion of hydrogen by pure iron begins about 400° C. and increases slowly up to 900° where a displacement occurs and the amount of occluded gas increases from 2.9 to 4.2 cc. Both parts of the curve may be considered to be linear but the slope in the γ-range is greater than that in the α-range. Later observations showed no occlusion of nitrogen below 900° C., but the displacement of the curve is considerably higher at the transformation point. The amount of N_2 occluded, however, decreases with increasing temperature. Very little hydrogen is occluded by chromium but the amount increases above 800° C. Up to 550° C. there was no occlusion of nitrogen by chromium. At 625° C. a reaction took place. The speed of this reaction was 270 times greater at 975° C. At 1200° C, the vapor pressure of the compound was less than 0.001 mm. Chromium increases the occlusion of nitrogen by iron considerably. The occlusion of hydrogen by molybdenum is very low especially at higher temperatures. The path of the curve has a maximum. Up to 800° C. molybdenum occludes no nitrogen. At that temperature about 2.0 cc. are absorbed. This is given up on cooling only under reduced pressure. Tungsten occludes neither nitrogen nor hydrogen. Observation on iron-silicon alloys indicate the occlusion of nitrogen in the γ-range is increased slightly. These are solid solutions. ESC(25)

Influence of the Composition on the Life of Annealing Pots. (Einfluss der Zusammensetzung auf die Haltbarkeit von Temperöfen.) W. S. MESSKIN. *Stahl und Eisen*, Vol. 50, Sept. 18, 1930, pages 1335–1336.
Abstract of a paper by N. G. Girschowitsch in *Mitteilungen aus dem Institut für Metallforschung in Leningrad (Russian)* Report No. 5, 1930, pages 8–36. The influence of some additional elements on the life of annealing pots was studied with reference to casting temperature, slag inclusions and blow holes. The life decreases with decreasing C content, reaching a minimum at 2.8% C and increasing again at still lower C contents. The amount of uncombined C should not exceed 1%. Si increases the life essentially, but should not amount to more than about 0.7%. The influence of Mn does not amount to much, though it decreases the impairing influence of S. S should not amount to more than 0.2%. P is most dangerous; in absence of special elements P should not be higher than 0.3%. Cr in small additions is favorable, neutralizing the unfavorable influence of P. More than 0.6% Cr, however, is not advisable due to an increasing of brittleness. GN(27)

The Effect of Carbon on the Transformation Points and Hardness of 12 Percent Chromium Steels. TAKEJIRO MURAKAMI & YOSHIRO FUJII. *Kinzoku no Kenkyu*, Vol. 7, Oct. 20, 1930, pages 505–523.
Using 8 specimens containing about 12% chromium in constant and varied carbon content less than 2.04% carbon the change of transformation points of these alloys was studied during heating and cooling under different conditions. For the determination of the transformation points, the magnetic analysis and the dilatometric method were applied. The temperature of the A_1 transformation on slow heating and cooling gradually falls and that of the A_2 transformation gradually rises as the carbon content increases. The A_2 change takes place at a lower temperature than the A_1 change and consequently the Ac_1 change is not observable by magnetic analysis. As the maximum heating temperature is raised or the cooling rate increases, the Ar_1 change is decreased and the Ar_2 change takes place at a markedly lowered temperature. This effect is conspicuous in rather low carbon steels, the effect being small in high carbon steels if the rate of cooling is not rapid, but if the rate is more rapid than the air-cooling the lowering of the critical point is marked and the Ar_2 transformation point is lowered with increasing carbon content. The Brinell hardness of specimens cooled under different conditions or those quenched and tempered was measured. The hardness of annealed steels gradually increases as the carbon content increases. The quenched steels show a maximum hardness when cooled from 1000° either in air or in oil, and as the heating temperature further rises the hardness decreases. When the heating temperature is lower than 1000°, the hardness increases with the increasing carbon content in the cases of both air-cooling and oil-quenching. If, however, the specimens are quenched from 1200°, those with about 0.3% of carbon show maximum hardness. The effect of cooling rate is small in cases cooled in air and in oil, the self-hardening property being markedly observable in both cases. When the quenched specimens are tempered from 900° C., the low carbon steels show an increase of hardness at about 500° and rapidly decreases on further rise of temperature, while in high carbon steels, no increase of hardness at about 500° is observable. When the quenched specimens are tempered from 1100° all specimens tested show marked increase of hardness at about 500°, the increase being marked in high carbon steels and the value being far greater than that of the quenched state. The microstructure of these specimens and its change under several heat treatments was also described. TM(27)

The Effect of Phosphorus on the Iron-Carbon Alloys. (1st Report.) YOICHI YAMAMOTO. *Rikagaku-Kenkyu-Sho Iho*, Vol. 9, Oct. 1930, pages 838–851.
Using electrolytic iron, ferro-phosphorus and white pig iron, many specimens containing less than 1.7% P and less than 3.5% C were prepared and the effect of C on the solubility of P in Fe and that of P on the graphitization of cast iron were studied by microscopic observation. At first the solubility of P in the binary Fe–P system was studied using alloys containing less than 2.5% P. It was confirmed that the solubility of P in Fe at the room temperature is 1.7% P. Next the solubility of P in Fe-C-P alloys with less than 1.7% P was studied. The solubility markedly decreases as the C content increases, and in air-cooled alloys from the melt, the Fe_3P is separated by adding 0.1% P, when the C content is 1.0%. If, however, the alloys are annealed for 2 hours at 920°, the Fe_3P is diffused and the solubility of P is increased, so that 0.3% P is dissolved in high C alloys containing more than 1.5%. The fact that the solubility of P decreases as the C content increases is attributed to the decrease of ferrite, in which the Fe_3P is dissolved, unless the Fe_3C is graphitized.
The relation between the microstructure and the hardness of these alloys was also studied. In binary Fe-P alloys, the hardness is markedly increased by adding P up to 1.7% in both air-cooled and annealed specimens. In Fe-P-C alloys with more than 2.0% C and 0.5–1.0% P, the Fe_3C is graphitized by annealing at 920° and the hardness is decreased. It is also shown that the P promotes the graphitization of Fe_3C. The facts above referred to, were demonstrated by many photo-micrographs. TM(27)

INSTRUMENTS & CONTROLLERS (28)

Automatic Regulation of Electric Foundry Furnaces. (La regulation automatique de fours electriques de fonderie.) A. LEVASSEUR. *Journal du Four Electrique*, Vol. 39, Aug. 1930, pages 296–300.
Advantages and some methods of automatic control of melting furnaces used in the foundry practice. See *Metals & Alloys*, Vol. 1, Oct. 1930, page 789. JDG(28)

The Automatic Reversing of Open Hearth Furnaces by the Temperature Difference Method. M. J. BRADLEY (Leeds & Northrup Co.) & J. W. KINNEAR, JR. (Carnegie Steel Co.). *Iron & Steel Engineer*, Vol. 7, Oct. 1930, pages 481–484.
Extensive studies were made on a 100-ton basic open hearth furnace to develop the best method of operating the regenerative system to definitely control the combustion rate and flame temperatures in the furnace. The study demonstrated that reversing operations can be more efficiently conducted automatically than manually. An outline shows the locations for thermocouples used in temperature study. WHB(28)

Automatic Combustion Control for Open Hearth Furnaces. R. W. SIMPSON (American Heat Economy Bureau, Inc.). *Iron & Steel Engineer*, Vol. 7, Oct. 1930, pages 485–487.
The control of combustion in the open hearth is becoming increasingly a more complex problem, following the use of 2 or more fuels at the same time. Best results are obtained by using different proportion of the fuels at different stages of the heat. Results are better with automatic control than with hand control. It is claimed that automatic combustion control will eliminate one of the variables from furnace operation which means fuel economy in amounts that will pay for the installation in a year or less. WHB(28)

Machine Control of Combustion in Metallurgical Furnaces of the Iron & Steel Industry. F. J. SHADGEN. *Iron & Steel Engineer*, Vol. 7, Oct. 1930, pages 490–497.
"A survey of the realities and an appreciation of the possibilities." The analysis has mostly the fuel aspect and its relation to greater process economy and plant efficiency. The application of machine control to open-hearth furnaces results in: (1) increase in production; (2) decrease in fuel consumption per ton; (3) longer life of furnace; and (4) better and easier metallurgical operation. Complete machine control is essential, engineering application is necessary and service and education of personnel are desirable. Includes discussion. WHB(28)

Temperature Regulators and Recorders Aid Production Processes. *Electrical World*, Vol. 96, Dec. 6, 1930, page 1037.
The Messina mill of the Aluminum Co. of America has demonstrated that automatic temperature regulators have a definite value in controlling quality of product. WHB(28)

Temperature Measurements without Pyrometers in the Metal Industry. EDMUND R. THEWS. *Canadian Chemistry & Metallurgy*, Vol. 14, Apr. 1930, pages 111, 113, 115.
Instances are pointed out where pyrometer control is non-essential. These include: (1) pouring temperatures where there is a more or less extended temperature interval determined by varying conditions, within which certain temperature-indicating reactions may take place; (2) practical working conditions may render the constant use of the pyrometer, either with thermocouple or optical, difficult; (3) where many melts are carried out per day with materials of practically similar composition, constant use of pyrometers would be tedious; and (4) the temperature-indicating reaction may be exact within a few degrees. Some good, simple methods are mentioned, such as determinations on strength of the color of the metal in a darkened room. The occasional use of pyrometers cannot be omitted except in a few cases, such as the determination of the pouring temperature of gun metal and of the ladling-out temperature of the white metal eutectic containing 54.6% tin, 41.9% lead and 3.6% antimony. WHB(28)

EFFECT OF TEMPERATURE ON METALS & ALLOYS (29)

Effect of Temperature on the Properties of Metals. (Report of Joint Research Committee on.) H. J. French, Chairman. Appendix 1, Comparative High Temperature Tests of Metals at Different Laboratories. H. C. Cross, Chairman Sub-Committee on Analysis and Correlation of Short Time Tests. Appendix 2, Some Long Time Tension Tests of Steel at Elevated Temperatures. J. J. KANTER & L. W. SPRING (Crane Company). *Preprint* for Vol. 30, Part 1, 1930, *Proceedings American Society for Testing Materials*, 40 pages.
Many details are discussed on methods of making short-time high temperature tensile tests, as to pulling speeds, temperature uniformity and measurement, strainometers and the plotting of stress-strain curves. Those making such tests will find that a careful study of the points brought out will aid in securing data that are, first, not fictitious; second, are directly comparable with the results of others. Appendix 2 gives very detailed evidence to show the value of a logarithmic method of plotting for comparing strain-hardening effects, and to bring out the fact that rates of creep are not necessarily constant. Long-continued tests often show a decreasing rate because of strain-hardening. Comparison of short-time tensile and long-time flow tests shows that, at the higher temperatures, the short-time tests do not reliably reflect the properties. At the higher temperatures, large grain size, whether obtained in cast as compared with wrought alloys, or by annealing as compared with quenching and drawing, or with rolling without annealing, tends to reduce creep. Step-loading, running awhile at one load and then increasing the load on the same specimen may give misleading results. The discussion deals primarily with methods, but the curves give much actual data on the flow properties of carbon and Ni-Cr cast steels, and on wrought carbon, Cr-Mo, Ni-Cr, stainless and 18–8 Cr-Ni steels. Some of the curves show results from observation of the same specimen for a year or more. HWG(29)

Properties of Non-Ferrous Alloys at Elevated Temperatures. C. L. CLARK & A. E. WHITE. *Preprint American Society of Mechanical Engineers*, Dec. 1–5, 1930, 7 pages.
This paper gives the results of an investigation of the properties of certain non-ferrous alloys at elevated temperatures as determined by short-time tensile and long-time creep tests. The alloys considered are of 4 groups: the nickel-copper, nickel-cobalt-titanium, copper-zinc, and copper-zinc-tin-series. The alloys are tested at temperatures both above and below their lowest temperature of recrystallization. Results indicate a superiority of the nickel-base alloys over the entire temperature range. The outstanding member of this group is Konel metal, which has short-time tensile properties at 1000° F. comparable to Enduro KA2, and the greatest creep resistance at this temperature of any alloy of which the authors are aware. Monel metal retains its properties well up to 800° F. Of the copper-zinc alloys, those containing 70% or more copper are superior to those with 60% of this element. None of these alloys can be used at temperatures much above 400° F. and for those containing lower amounts of copper, 300° F. is believed to be the maximum working temperature if stresses of appreciable magnitude must be considered. (29)

Materials for High Temperature Service from the Creep Design Standpoint. J. J. KANTER & L. W. SPRING. *Metals & Alloys*, Vol. 1, Dec. 1930, pages 880–882.
A general discussion. Steam power, oil refining and numerous chemical processes demands for corrosion resistance and high temperature equipment are making unprecedented requirements of the metallurgist. At elevated temperatures the real limit of elasticity is quite low and equipment cannot be designed in a practical way upon the theory of stress strain equilibrium. Creep must be accepted and dealt with at high temperatures. Corrosion and other deterioration are factors in dimensioning the load carrying members and fixing stresses. A tabulation of creep values for a variety of materials is presented. The popularity of 18–8 Metal is largely due to its corrosion resistant properties although it possesses excellent strength properties at high temperatures. The highest temperatures at which the metals will safely support 1000 lbs./in.^{2} stress with no more than 1% creep in 10,000 hours ranges from 450° F. (230° C.) for Rolled Naval Bronze to 1600° F. (870° C.) for 18–8. The steels which seem to have the highest strength and toughness at this higher temperature and above are of the highly alloyed austenitic type. There is need for data on the effect of temperature on Poisson's ratio (ratio of lateral contraction to extension). This may be determined from the combined results of tension and torsional moduli. The total amount of deformation due to creep which can be tolerated in turbine parts must not exceed 0.2% in 20 years. ESC(29)

Temperature Coefficient of the Modulus of Rigidity of Aircraft Instrument Diaphragm and Spring Materials. W. G. BROMBACHER & E. R. MELTON (Bureau of Standards). *Report* No. 358, *National Advisory Committee for Aeronautics* (1930), 16 pages, 11 references (Supt. of Documents, Washington, D. C. 10¢).

In design of aircraft instruments which must operate at temperatures between −50° and + 50° C., a knowledge of the temperature coefficient for the elastic moduli (Young's modulus and the modulus of rigidity or elasticity in shear) is necessary. Data for the modulus of rigidity and for its temperature coefficient are given for Aluminum, Duralumin, Monel, Brass, Phosphor Bronze, Nickel Brass, Coin Silver, for 1.4, 0.9 and 0.7% C carbon steels, for Cr V and Cr Mo steels with about 0.55% C, 1% Cr and 0.2% V or Mo, also for 0.8% C 13% Cr stainless steel. For most of these data were obtained in various conditions, hard-drawn, annealed, and quenched and tempered. Approximate values of the modulus of rigidity at room temperature are: Al and Duralumin 3.7 to 4, Monel 9.3 to 9.7, Brass 4.8 to 5, Phosphor Bronze and Nickel Brass 6.2, Coin Silver 4.3, the various steels aside from stainless 10.9 to 11.5, stainless 12.4; all figures in 10^6 lbs./in.^{2} Average temperature coefficients are given, but as these differ in many of the alloys, depending on whether the sample is hard drawn or annealed, and on the heat-treatment in the case of steels, and in some cases are quite different at different temperatures, the original must be consulted for them. For example, the Cr Mo steel water quenched from 870° C. and tempered at 100° C. has a temperature coefficient of the modulus of rigidity of -21×10^{-5} for the interval −15° to 0° C. and one of -45×10^{-5} for the interval +25° to +50° C., and the average coefficient for the interval −20° to + 50° C. for annealed Al is -100×10^{-5} to -135×10^{-5} while that for half-hard Al is -62×10^{-5}. The average coefficients for the various steels range from -23×10^{-5} to -48×10^{-5}, while those for the non-ferrous alloys (exclusive of Al as given above, of duralumin with -62×10^{-5} and coin silver with -56×10^{-5}) range from -34×10^{-5} to -52×10^{-5}. Properties of Steels at High Temperatures. (Les Qualité des aciers a haute température et leurs emplois à la nouvelle chafferie de la centrale d'Issy-les-Moulineaux.) C. GALATOIRE-MALEPARIE. *Génie Civil*, Vol. 95, Oct. 19, 1929, pages 373–377.

A review of recent studies of behavior of special steels at high temperatures and high pressures with special reference to equipment of the Issy-les-Moulineaux steam-electric plant. Considers special treatment of steels used and gives results of tests and operating experience and computation of the factor of safety. (29)

Carburizing and Graphitizing Reactions between Iron-Carbon Alloys, Carbon Monoxide and Carbon Dioxide. M. L. BECKER. *Foundry Trade Journal*, Vol. 42, June 12, 1930, page 439; *Iron & Coal Trades Review*, Vol. 120, May 23, 1930, page 841.

Summary from paper read at annual meeting of the Iron and Steel Institute. See *Metals & Alloys*, Vol. 1, Oct. 1930, page 789. RHP + VSP(29)

The Hardness of Cast Iron in Relation to Temperature. FRANZ ROLL. *Foundry Trade Journal*, Vol. 43, July 3, 1930, page 5; *Giesserei*, Vol. 17, Sept. 5, 1930, pages 864–870.

Abstract translation of a paper read before the German Foundry Technical Association. The hardness in relation to C and temperatures was demonstrated by using space lattice obtained by researches of Robin. Time is the most important factor for the hardness of cast Fe. The hardness of cast Fe falls considerably even at 100° C. Refers also to researches of other investigators. VSP(29)

Metals and Alloys for Use at High Temperatures and Pressures. H. W. GILLETT. *Metals & Alloys*, Vol. 1, Dec. 1930, pages 865–866.

An editorial presenting a general discussion of the demands upon metals and alloys in high temperature and high pressure application. Emphasis is placed upon the importance of refined testing methods for determination of these properties. ESC(29)

Alloys for Use at High Temperature. W. ROSENHAIN & C. H. M. JENKINS. *Iron & Coal Trades Review*, Vol. 120, May 16, 1930, pages 800–804.

Discussion May 23, 1930, page 840. Abridged from a paper before the Iron and Steel Institute, May 1930. See *Metals & Alloys*, Vol. 1, Aug. 1930, page 686. RHP(29)

Results of Endurance Load Tests on Various Construction Steels at Elevated Temperatures. (Ergebnisse von Dauerbelastungsversuchen mit verschiedenen Baustählen bei hohen Temperaturen). E. POHL, H. SCHOLZ & H. JURETZEK. *Stahl und Eisen*, Vol. 50, Sept. 18, 1930, pages 1330–1331; *Archiv für Eisenhüttenwesen*, Vol. 4, Aug. 1930, pages 105–110.

After describing an improved test method for studying the behavior of steels at elevated temperatures, the authors give results of long-time load tests which they carried on on carbon steel, nickel steel and molybdenum steel sheets of 25 mm. thickness. The load was generally increased in steps, the temperature range examined being 300° to 500° and 350° to 500° C. For the evaluation of the results of a stress-elongation diagram combined with an elongation-time diagram was chosen to clearly present the physical properties under a static endurance load at high temperatures. The endurance strength amounted for the carbon steel to 15.2 kg./mm.^{2}, at 300° C. to 8.45 kg./mm.^{2} at 400° C. and to 5.70 kg./mm.^{2} at 450° C. The values of endurance strength for the nickel steel sheet are: Above 20.0 kg./mm.^{2} at 350° C., 9.85 kg./mm.^{2} at 450° C. and 5.38 kg./mm.^{2} at 500° C. The results for the molybdenum steel are: 15.0 kg./mm.^{2} at 450° C. and 11.2 kg./mm.^{2} at 500° C. Molybdenum steel evidently shows the most favorable behavior at higher temperatures. Finally the method employed for this investigation is compared with the method by A. Pomp and A. Dahmen, *Mitteilungen Kaiser Wilhelm Institut für Eisenforschung*, Vol. 9 (1927) pages 33–52. (Also *Report* 98, *Material Committee of the Verein deutscher Eisenhüttenleute.*) GN(29)

REDUCTION METALLURGY (31)

Some New Developments in Aluminum Production. (Quelques progres recents dans la fabrication de l'aluminium.) *Journal du Four Electrique*, Vol. 39, July 1930, pages 259–260.

Brief sketch of Haglund, Hall, Pedersen, and Blanc processes for preparation of alumina from bauxite. The process for making Fe free Al_2O_3 by a wet method of Seailles (Echo des Mines et de la Metallurgie, Jan. 20, 1930) is being introduced in industrial use in France. Innwerk in Germany is able to produce Al with 23 kwh./kg. Arvida plant claims results better than 20 kwh./kg. JDG(31)

The Coley Process Applied to Zinc Production. *Industrial Chemist*, Vol. 6, Sept. 1930, pages 357–360.

This is a description of the process used at the Dartford (England) works of the Zinc Manufacturing Co., Ltd., for reducing calamine with nascent carbon. Cool fuel oil is lead into the presence of the hot ore (1000–1100° C.) in a large drum, where it is cracked producing the nascent carbon. The reaction is rapid; 95% of the zinc is recovered as a black powder, of which, 80–85% is finally brought into the form of ingots. The process is applicable to other ores. After the plant at Dartford had been in operation for a year, the Zinc Manufacturing company was formed, with a capital of one million pounds for the purpose of erecting a plant to produce 50,000 pounds of spelter annually. Another plant is being built at Tunis. MPB(31)

Autochrome Process. A. J. M. SHARPE. *Engineering & Mining Journal*, Vol. 128, Nov. 16, 1929, page 769.

This process produces iron and steel from chrome ore. The process parallels, somewhat, the auto-doubleage process for calorizing tubes in that either nickel chloride or cobalt chloride is mixed with the chrome ore. Tungsten molybdenum, manganese, nickel or cobalt may be similarly used. The autochrome process introduces no carbon and is cheap. WHB(31)

The Form of Copper in Converter Slag. F. S. WARTMAN & W. T. BOYER. *Metal Industry* (London), Vol. 36, May 9, 1930, pages 504–507; May 23, 1930, pages 553–556.

One of a series of reports giving results of investigation conducted by Southwest Experiment Station of the U. S. Bureau of Mines, Reprinted from U. S. Bureau of Mines. Report of Investigations No. 2985. See also *Metals & Alloys*, Vol. 1, Oct. 1930, page 790. VSP(31)

The Crumbling of Blast-Furnace Slag. FRITZ HARTMANN & ALMUTH LANGE. *Iron & Coal Trades Review*, Vol. 120, May 9, 1930, page 753.

Abstract of a paper from a recent issue of *Archiv. für Eisenhüttenwesen.* Four types of crumbling are found to be: (1) Crumbling of the lime, caused by the beta-gamma transformation of dicalcium silicate; (2) Crumbling due to iron, recognizable by soaking in water; (3) That of manganese, due to excessive manganese content; (4) Due to low strength owing to vitreous inclusions. Discusses the methods of detecting crumbling. Material is based on the authors investigations. RHP(31)

Lead Refining at the Bunker Hill Smelter of the Bunker Hill & Sullivan Mining & Concentrating Co. ALFRED F. BEASLEY (Bunker Hill & Sullivan Mining & Concentrating Co.). *Technical Publication* No. 303, *American Institute of Mining & Metallurgical Engineers*, 1930, 9 pages.

Describes in detail Parkes process in which 2 crusts or skims are taken from the desilverizing kettles. JLG(31)

An Experimental Inquiry into the Interaction of Gases and Ore in the Blast Furnace. WILLIAM A. BONE, L. REEVE & H. L. SAUNDERS. *Iron & Coal Trades Review*, Vol. 120, May 9, 1930, pages 754–758; discussion, May 16, 1930, page 795.

Abridged from a paper before the Iron & Steel Institute, May 1930. See *Metals & Alloys*, Vol. 1, Aug. 1930, page 686. RHP(31)

Continental Blast Furnace Practice. F. CLERF. *Iron & Coal Trades Review*, Vol. 120, May 23, 1930, pages 833–835.

From a paper read before the West of Scotland Iron and Steel Institute and published in the journal of the Institute. Reviews recent developments, especially German but deals with others. Discusses sources of raw materials and coke as well as the actual blast furnace and blast furnace practice. See *Metals & Alloys*, Vol. 1, Aug. 1930, page 686. RHP(31)

Sintering Limonitic Iron Ores at Ironton, Minnesota. PERRY G. HARRISON (Evergreen Mining Co.). *Technical Publication* No. 284, *American Institute of Mining and Metallurgical Engineers*, 1930, 12 pages.

Ore sintered in continuous Dwight-Lloyd machines. Gives flow sheet for plant at Evergreen Mine. JLG(31)

Tin Metallurgy in Great Britain—1929. A. S. FITZPATRICK & HAROLD S. ELFORD. *Proceedings Australasian Institute of Mining & Metallurgy*, No. 78, June 30, 1930, pages 81–161.

A description of geology, treatment plants at 9 mines (with flow sheets), ore dressing machinery, roasting practice including arsenic recovery and refining of crude arsenic trioxide, magnetic separation, costs of treatment, recovery of tin oxide from mill waste, flotation in tin metallurgy, recovery of tungsten, sampling, assaying, sale of tin concentrates and smelting practice at 2 smelters. AHE(31)

Corrosion-Ometer

An Instrument and a Measure For Determining Corrosive Effects

One of the greatest destroyers of metals and alloys in their useful life is Nature herself. The resistance of these materials to the reactions of Sun, Rain, Cold, Heat, and the various combination effects of the same are frequently a determining factor in use. For the laboratory to be able to reproduce these effects under controlled conditions for the purpose of study, analysis, and charting determinations, is therefore of vital importance.

Weather-Ometer is the only instrument known today that gives accurate, accelerated weathering under controlled conditions as to order, intensity, and duration. With this machine it is possible to test up to 60 samples at one time of different metals and alloys and make a detailed progressive study of surface breakdown due to corrosive action. We have records of interesting and valuable investigations of this nature that have been made with Weather-Ometer of which we will gladly tell you more fully.

Write today for complete details regarding Weather-Ometer and its uses. Ask for Bulletin MA-2.

BOOK REVIEWS

Strength of Materials. By S. TIMOSHENKO. D. Van Nostrand Company, New York, 1930. Cloth, $6^1/_4 \times 9^1/_4$ inches. Part I. Elementary Theory and Problems, 368 pages. Price, $3.50. Part II. Advanced Theory and Problems. 334 pages. Price $4.50.

In the preface the author states "It is the aim of this book to present problems such that the student's attention will be focused on the practical applications of the subject." This purpose has unquestionably been achieved and the author has been very happy in his selection of illustrative problems which cannot fail to carry out his expressed intention. These problems, several hundred in number, are of 3 types; those in which a solution is completely outlined and answer recorded; those in which answers only are noted; and a considerable number in which no aid to solution is given. Regardless of his own method of teaching, each instructor will thus find ready material to suit his purpose. The figures are delightfully clear and never unduly involved.

Part I fully and carefully covers all the material needful to the general engineering student. In addition to the matter usually presented the text is extended in nearly every section to embrace numerous cases ordinarily omitted. This makes it applicable for courses where this more advanced work is desirable; yet with judicious omissions on the part of the instructor it may be adapted to the needs of more elementary courses without loss of coherence. There appear a few outstanding features worthy of note. The early introduction of deformation in frames and members, will tend to emphasize to the student this item so often ignored in texts of this kind. Stress analysis by means of Mohr's circle gives a foundation very useful in later advanced work. Particularly commendable are the discussions of non-circular and irregular sections in torsion, and the non-symmetrical sections in beams. Practically the last third of this part is devoted to the somewhat unusual material: plastic bending, combined bending and twisting and energy of steam.

Part II is obviously and admittedly for "advanced students, research engineers and designers." Beginning with complex problems in bending and passing on to curved beams, the writer continues his policy of using obviously practical examples to finished material requiring the development of special analyses. Among these may be noted the study of stresses in flywheels, perforated plates and pipe bends. After the usual development for thin plates and diaphragms the text proceeds to a study of stress in surfaces of revolution and finally to the valuable material concerning local stress in both shells, the Bellville Spring and shrink fits. The timeliness of the book is particularly illustrated by the inclusion of a chapter on stress concentrations which treats the matter from both the purely mathematical and the photo-elastic methods of analysis. Contrary to most presentations the physical properties of materials have been reserved for the last chapter of the second volume and though it is not so listed this chapter appears in the nature of an appendix.

While the opening pages of Part I give all the inherent qualities of matter needful for an analytical consideration of the subject, some instructors may feel the need of using parts of this last chapter when beginning the subject.—IRVING H. COWDREY.

Metallstock und Wirtschaftlichkeit. By RUDOLF HOFFMAN. Verlag Wilhelm Knapp, Halle, 1929. Paper, $6^1/_2 \times 9^1/_2$ inches, 104 pages. Price 9.80 RM.

The subtitle to this tract is A CONTRIBUTION TO THE QUESTION OF INTEREST CHARGES IN SMELTER WORKS, although the subject matter is really broader than this, since it contains a discussion of the general economics of smelting and refining, drawing upon lead-silver refining for illustrative details and calculations.

In the foreword the author states that the present stringent economic conditions in Germany call for special watchfulness in keeping operating capital and interest charges to a minimum. However, business everywhere seems to have learned the lesson of low inventories. Henry Ford in one of his books relates that Ford parts on freight trains en route to his assembly plants comprise a major portion of his "stock."

After dealing with the factors to be considered in appraising ores and metal stock, an extensive discussion is given of the definition of metal stock (from ores to the refined metals) and of the manner of calculating interest charges on it. In a very thorough-going treatment it is shown how the choice of the most economical smelting and refining process in any given set of circumstances may depend on the requisite metal stock and consequent interest charges for that process. A large number of detailed calculations are shown throughout the text and in tables at the end. While the information is based largely on European practice, the author shows an acquaintance with American metallurgical literature.

The author appears to be well informed on both the metallurgical and economic sides of the subject. The style is clear and stimulating. The book should appeal to executives, metallurgists and accountants in the smelting and refining industry, especially that of lead-silver.—S. EPSTEIN.

Lecons de Siderurgie professees a l'Ecole des Mines de St. Etienne. By P. ANGLES D'AURIAC. Enlarged and revised by J. Estour. Dunod, Paris, 1930. Paper, $6^1/_2 \times 10$ inches, 716 pages. Price 131.10 Fr.

There are three kinds of metallurgical books. The purely scientific do not need any comment. Those written by practical men beginning with the statement that the author is familiar with half a dozen plants and never had time for theory might be of some use to another set of even more practical men. College text-books are memorized for examinations and then forgotten as soon as possible.

Writing them down to the level of the audience instead of bringing the latter to the mental plane of the writer creates yearly a flock of young asses serenely convinced that in a blast furnace the reduction with carbon monoxide is the only reaction worth speaking about. Left to themselves and coming in contact with the actual operation of the furnaces most of them succumb to the inevitable and become deeply convinced that the application of theory to mill practice is bunk.

There is no need for giving in school a choking dose of facts and details. They will pass undigested and with only an unpleasant memory for the future. What is needed in theory is the sound representation of basic facts with the curtain lifted enough to let one peep at the immense complexity of them and the beauty of scientific logic gradually but inevitably leading to complete understanding.

The practical side of the art, protean in its very nature, cannot be covered by description of apparatus and generalities of the processes. Nor will it be wise to go into minutest analysis of some of them step by step. An insight into the phenomena underlying the major phases or peculiarities of the processes and apparatus will be immeasurably more helpful, giving to a young man a foundation on which to apply his judgment when it is matured in plant work.

One will return to the book of Professor d'Auriac long after all others are completely forgotten. The profound erudition of its author permitted him to select the very best tools for illustration of any given point. Mathematics remove mysteries from the manner in which particles of the burden are or ought to be distributed in a stack for the best results. Physical chemistry takes care of the equilibria occuring during processes. When some disputable matter comes to light such as the optimum lines for a blast furnace it is not left to guess or speculation, but the author goes directly to the result already obtained along similar lines. He is equally familiar with, say, Rachette's oval furnace in the Urals of the sixties or No. 1 Aliquippa stack blown in in 1927. In questions of vital practical import his experience and acquaintance with the plants of the world leads to unmatched treatment of the subject as is the case, for example, of desulphurization in the mixer. He helps himself with equal ease to the data obtained by Matsubara or McKinney with his associates or to conclusions reached by Neilson of the hot blast fame during the latter's experiments on dry blast more than a century ago. There is no piling of facts, ideas or statistics for the sake of record only. Everything written has a definite aim either to remove some objections to a conception, to explain the mechanism of some reaction, to point out the characteristics of an apparatus, its peculiarities and behavior or to lead the metallurgist to clear understanding of what might happen after certain changes in equipment or practice. Not a single question of any magnitude is omitted.

The hastiness of the publishers seems to be the major defect of the book. At the time of his death Professor d'Auriac had the book which contained the very latest ideas of the contemporary practice and thought. A worthy pupil of the master, Mr. Estour, followed the ideas of his preceptor when enlarging and bringing to date his work and did it so that no difference between the original and enlarged work can be perceived either in spirit or in comprehensiveness with the exception that the latter contains all new developments of the past years with literary references reaching papers published in 1930 and world statistics brought up to 1927. The thoroughness of the work requiring very considerable time, prevented Mr. Estour from covering the whole ground in the time given to him. From four major divisions of the book, preparation of metallurgical fuel, blast furnaces, Bessemer process and open hearths, two first received the full benefit of the reviewing while the last two on many occasions are a score of years behind the times. Were the whole book brought to the excellency of its first half it could be unconditionally recommended to all metallurgists. As it stands now any reader wishing to refresh and enlarge his knowledge of coking practice or blast furnaces cannot do anything better than to read the combined efforts of the authors. An open hearth man or a Bessemer blower will, however, find but little which will directly bear on the present-day practice.—JOHN D. GAT.

Wärmewertigkeit, Wärme- und Gasfluss, die physikalischen Grundlagen metallurgischer Verfahren. By HUGO BANSEN. Verlag Stahleisen, Düsseldorf, 1930. Cloth, $8^1/_2 \times 11$ inches, 61 pages. Price 10 RM.

This work outlines a treatment of the thermal efficiency of high temperature processes distinctly superior to the common type of heat balance. Thermal data are assembled in diagrams which show side by side the quantity of heat required and the amount available together with the temperatures at which these quantities are demanded and supplied. The details of these rather intricate diagrams are treated at length in auxiliary sections at the end of the book. They present very effectively the increase in temperature possible by the utilization of waste heat in preheaters. Numerous thermochemical equations and tabulated data are also given.

The combination of operating data with thermochemical calculations is illustrated chiefly in a thorough exposition of the thermal efficiency of the iron blast furnace. Other processes discussed include the operation of the open-hearth furnace and the basic converter, sponge iron manufacture and the utilization of various fuels.

The importance of time in a quantitative study of metallurgical heat requirements is also emphasized. This is illustrated by studies of the heat transfer in regenerators and recuperators, blast-furnace stacks, and Dwight Lloyd sintering machines. The flow of gases through layers of solids is discussed in connection with the last two illustrations. Time studies are shown to be useful in choosing the size of unit most efficient for producing given tonnages.

The table of contents includes lists of tables and diagrams as well as a complete list of subject headings but there is no alphabetical index. The sources of the thermochemical data are not stated, though numerous references to earlier work on heat balances are cited. Misprints are not infrequent in the explanatory sections.

The study of thermal processes without resort to formal thermodynamics is effective, and the diagrammatic representation is especially welcome to the American reader.—G. L. FREAR.

Die Gussröhren Herstellung in der fester Form und Schleuderform. BY H. WEBER & H. HERMANNS. Heft 3, 1927. Paper, $6^1/_2 \times 9$ inches, 68 pages. Price 4.50 RM.

Herstellung der Abgüsse in der Graugiesserei. BY E. BAUER. Heft 11, 1930. Paper, $6^1/_2 \times 9$ inches, 72 pages. Price 6.20 RM.

Die Maschinenformerei und Kernmacherei in der Eisengiesserei. BY E. BAUER. Heft 12, 1930. Paper, $6^1/_2 \times 9$ inches, 72 pages. Price 4.80 RM.

Parts of H. Hermanns' series—Die Betriebspraxis der Eisen, Stahl und Metallgiesserei. Published by W. Knapp. Halle, Germany.

These are elementary treatises in a series on foundry practice. In the one on cast iron pipe, Weber describes ordinary molding practice. The machine molding and sand handling equipment of a large German plant is described. In the second part of this, Hermanns describes the various processes for centrifugal casting of pipe, the difficulties encountered and discusses the structure and physical properties of the product.

Bauer deals with the making of gray iron castings, touches on the mixing of irons, quite thoroughly discusses gating, chills and risers, and deals exhaustively and interestingly with casting stresses and their avoidance. Sketches show why cracking or warping occurs, and how the design of the part may be made so as to avoid these troubles.

In the one on machine molding and core making Bauer describes matchplates, strippers and squeezers, jar-rammers and sand slingers, various systems of mold transportation, and core-making machines of various types. The illustrations give a good idea of German practice.

All the booklets are well indexed.—H. W. GILLETT.

Techno-Diktionär. By HUBERT HERMANNS. Published by the author, Berlin, 1929. Paper, $4^1/_4 \times 6$ inches, 432 pages. Price $2.75.

This is a three-way technical dictionary, containing English, German and Italian terms, and will be a convenient auxiliary to the more general book. It gives no information save a bare translation of the term involved.—M. L. MOORMAN.

Ingot Contour and Its Relation to Sound Steel. Gathmann Engineering Company, Baltimore, 1930. Half cloth, 6×9 inches, 90 pages. Price $1.00.

The seven major stages in steel production from the molten to the bloom are listed. Classes of steel are next discussed: fully-deoxidized, semi-deoxidized and rimming steel and the effect of molds are considered. Other subjects: solidification, inspection, ingot taper, effects of mold design on solidification, essentials to soundness, ingot surface, segregation are covered. R. R.

The Mineral Industry, Its Statistics, Technology and Trade during 1929, Volume XXXVIII. Edited by G. A. ROUSH. McGraw-Hill Book Co., Inc., New York, 1930. Cloth, $6^7/_8 \times 9^3/_8$ inches, 845 pages. Price $12.00.

The latest volume of this exact and complete guide-book of the mineral industries is now available. The contributors should be congratulated on the conciseness and value of their various sections; the editor has continued his laudable idea of obtaining contributors who are authorities in the various fields.

Additions include lists of Trade and Professional Organizations and Diamite Statistics. Changes occur in the combining of Beryllium, Bismuth, Cadmium, Selenium, etc., under the heading of Minor Metals, and Bromine, Feldspar, Fuller's Earth, etc., under Minor Nonmetals.

The book itself is 43 pages larger than last year's edition.—W. B. DILLINGHAM.

Symposium on Aircraft Materials. Published by American Society for Testing Materials, Philadelphia, 1930. Cloth, 6×9 inches, 189 pages. Price $2.00.

The seventeen papers and discussions presented at the Aircraft Symposium held at the 1930 A.S.T.M. meeting (which have previously been abstracted in the Abstract Section), are now available in bound form. This was a valuable symposium dealing with alloy steels and light alloys, heat-treatment, welding, metal joints, specifications, materials control, etc.—H. W. G.

Aluminum in Aircraft. Aluminum Company of America, Pittsburgh, 1930. Paper, 159 pages. Price 50 cents.

This is one of the useful and authoritative handbooks of the Aluminum Company of America which contains much technical information.

The approximate composition, methods of heat-treatment, physical constants, mechanical properties and corrosion-resistance of the wide range of aluminum alloys applicable to aircraft construction are given in detail. Short-time high-temperature tensile properties are included.

Crank cases, pistons, propellers, spars, beams and girders, fuel tanks, wing and fuselage coverings, etc., etc., are discussed as to materials and fabrication. Welding, riveting, and anodic treatment as a preparation for protective coatings are thoroughly discussed, and much data given on corrosion prevention and the inspection of parts subject to corrosive conditions. The available commercial shapes are listed.

While the advantages of metal construction are stressed, the book is not primarily propaganda; it is a compendium of technical information, and states the drawbacks and limitations of the aluminum alloys as well as the good points. It is written from a sound engineering point of view.—H. W. G.

A.S.T.M. Standards. Issued Triennially. Pt. I. Metals, 1000 pages. Pt. II. Non-Metals, 1214 pages. Published by American Society for Testing Materials, Philadelphia, 1930. Price each volume $7.50; half leather $9.00; both parts $14.00; half leather $17.00.

The A.S.T.M. standards form an important compendium not only of accepted standards, but also of methods of testing, and, to a lesser degree, of recommended manufacturing practice.

In the volume relating to metals are 76 standards dealing with steel, 9 with wrought iron, 11 with pig or cast iron, 8 with ferro alloys; a total of 104 in the ferrous field, while there are 66 on non-ferrous metals and alloys. Approved methods for chemical analysis are given for the determination of most of the constituents of the alloys dealt with.

Very definite modes of procedure have been adopted for tensile, compression, magnetic and Brinell hardness testing, and recommended practices are advanced for metallographic examination, thermal analysis and radiography.

It is interesting to note that radiography, a new-comer, has been brought to a point where acceptable methods can be stated, while test methods for determination of impact resistance, endurance under repeated stress, resistance to corrosion and to wear, or for the determination of properties at high-temperatures, remain un-defined.

Of course, most of these subjects are under discussion and study by the Society, with symposia or at least frequent articles devoted to them, and several of the items are being actively studied by research committees. However, the study of only a few of the causes for deterioration and failure of metals has advanced to such a point that we really know how to measure the properties concerned.

That accelerated methods of corrosion-testing of metals are not considered reliable is well indicated by the absence of any such methods from the list of standard tests, and the fact that many of the research committees have sponsored extensive exposure tests for evaluating corrosion tendencies.

The only test relating to corrosion is one to show the presence of active sulphur or sulphur compounds in gasoline, by the use of metallic copper.

The standards of the A.S.T.M. have been filtered through the minds and experience of many representatives of producer, consumer and "general interests," and in many cases are based on exhaustive research. There is a growing tendency to determine the fundamental engineering facts required for the formulation of a sound specification by means of research rather than by snap judgment.

The volumes are indispensable to producers and consumers of the commodities dealt with.—H. W. G.

La Soudure Electrique a l'Arc. BY R. SARAZIN. Journal de l'Industrie et de la metallurgie francaises, Paris, 1930. Paper, $6 \times 9^1/_4$ inches, 348 pages. Price 38.50 francs.

For American practice, this book is of little value since much antiquated information, at least for Americans, is contained in it despite the recent publication of the book. Some of the illustrations, for example those on pages 48, 89 and 98 in the first part, might well have been omitted; and, to the American welder, it is a strange spectacle to see a man holding the mask before his face with his hand instead of having it fastened to his head, leaving him with the free use of both hands.

In contrast, the second part on the apprenticeship of the welder is made valuable by the detailed instructions it contains. The chapters on composition and building up of shapes from structural material and the carrying out of repairs, with illustrations of some difficult cases, are also instructive. A special chapter is devoted to the electric welding of non-ferrous metals.

For those who read French, the book is quite instructive, especially in fundamentals, if one is able to disregard out-of-date information.—M. HARTENHEIM.

Metaux et Alliages. BY C. GRARD & J. COURNOT. Berger-Levrault, Paris, 1930. Three volumes, paper, $6^1/_2 \times 10$ inches. Vol I, 321 pages, Vol. II, 295 pages, Vol. III, 317 pages. Price 3 volumes 110 Fr. Each Volume 40 Fr.

In three volumes of *Metaux et Alliages* the authors placed before themselves the problem of presenting the whole enormous building of metallurgical knowledge from ore dressing to protective coatings. A stupendous problem and exceedingly difficult to accomplish considering the size of the work, only 933 pages of large type. General Grard and Dr. Cournot solved it in an original way. Offering their thoughts along the usually accepted program—the theory and testing in the first volume, ferrous metallurgy in the second and non-ferrous material in the third, they removed from the stage so much detail that with the exception of some subjects the series appear as a skeleton of the science.

The promise made in the preface of bringing to light the very latest developments is fulfilled in some cases, such as testing and examination of materials, heat treating of many alloys and means for protection of metals from corrosion. At the same time several innovations of the past few years are not even mentioned. Among these are application of high frequency electric furnace to steel making, introduction of tungsten carbide, hardening of copper by precipitation, etc. Other points are passed sometimes with only a brief mention. X-rays are dismissed in five lines. Brasses, including their preparation, are treated on nine pages. The description of ghost lines as streaks of non-metallic inclusions, unquestioned acceptance of beta iron or attribution of soft spots on abnormal steels to low carbon content must be termed at least original.

The publishers of the set made of it an irreproachable job, one of the best metallurgical treatises coming from France in a long time. However some misprints occur in the most inconvenient places as when all standard specifications for aviation steels call for 0.04% phosphorus, *minimum*. The use of photomicrographs is rather peculiar. High points of ferrous metallurgy are sufficiently illustrated but the non-ferrous field is not even touched with the exception of six excellent color photographs of aluminum alloys.

We do not live in an age when a Newton could tell everything which was known. A substantial acquaintance with a single speciality now demands more than a lifetime of a capable man. A really good book is placed here in an equivocal position by the lack of some appropriate adjective in the title limiting its scope to testing, heat treating and protection of metals. Both authors have these subjects at their finger tips and know how to convey the information to others. The presentation of these subjects is well thought over, clear and complete. Giving a very large amount of material applicable to any conditions it brings the French viewpoint on many vital points of testing and protection, indicates some new methods of approach and describes much equipment not familiar in the states. The rest of the book is elementary, though remarkably well written.—J. D. GAT.

Materials of Engineering Construction. BY FRANCIS W. ROYS. Ronald Press, New York, 1930. Cloth, $6 \times 8^1/_2$ inches, 331 pages, 167 figs. Price $4.00.

The book is intended as a text for engineering students, to familiarize them with their materials, and is well planned for this purpose. The execution of the details, however, is frequently poor—particularly in those parts dealing with metals. In these days of intense specialization it is unfair to expect an engineer to write a treatise on metallurgy to meet the approval of metallurgists, but the value of the book would have been greatly enhanced had the author been assisted in all parts by specialists in the various metals discussed, as he was in writing the sections dealing with malleable cast iron, wrought iron, and to some extent the part on aluminum and its alloys. For other metals the author himself endeavored to select his material from the mass of literature and made some unfortunate choices.

It is, perhaps, the mere fact of the reviewer's own specialization which makes him criticize most severely the section dealing with copper and its alloys, but any metallurgist would be unfavorably impressed if he saw a peritectic reaction in the most important non-ferrous equilibrium diagram shown as a sloping curve! The copper-zinc diagram, which shows the old beta eutectoid now known to be a polymorphic change, is not even correctly reproduced from the source given. The statement that alloys of copper with 35–45 percent zinc may "even contain fine delta under peculiar conditions" prepares one for the statement that a 60–40 brass, if annealed and quickly cooled from 600° C. becomes homogeneous beta, which will withstand considerable cold rolling. This is supported by an excellent photomicrograph showing the normal structure of twinned alpha and beta with the caption stating it to be nearly homogeneous beta solid solution.

The section on the manufacture of steel probably has enough detail for the engineer, and the principles of heat treatment are fairly well explained on the basis of the diagram. The engineer is given no information as to practical methods of heat treatment, neither is he given complete sets of figures showing the variation of properties with heat treatment.

The theory of corrosion is well presented, mainly on the basis of Evans' work, but no mention is made of selection of alloys for use under various corrosive conditions, which is of great importance to the engineer.

The statements that steel is nitrided at 500° F. and that lead is nearly four times as heavy as iron may, perhaps, be the printer's errors, as also undoubtedly are "0.085%" and "85 to 150%" carbon given as the composition of eutectoid and tool steel respectively on page 223, "magnesia" for magnesium on page 231, "kisle" for kish on page 144 and "dioxidize" for deoxidize on page 246.

The book is nicely bound, well printed on good paper and the many illustrations are excellently reproduced. The index is one of the best and most complete that the reviewer has seen, and it is to be regretted that the material is hardly worthy of it.—CYRIL STANLEY SMITH.

Lehrbuch der Metallhüttenkunde. By VICTOR TAFEL. Verlag S. Hirzel, Leipzig, 1927. Cloth, 7 × 10 inches, 426 pages. Price 27 RM.

The author has collected his information from widely scattered sources such as books, transactions of different societies and periodical technical papers which have been published during the last few years. It would be unjust to say, however, that the result is simply the quoting of other men's words.

Dr. Tafel had years of personal experience in the mining field before he accepted his present position as Professor of Mining and Metallurgy in the University in Breslau. His experience as a scientist and a practical engineer is easily discerned in his book. This book is intended first as a text-book for German students to instruct them in the latest foreign literature, especially American, on the subject of metallurgy. He is also anxious to have the practical end in mind when comparing different methods and in this way he gets away from the usual text-book which the student often finds dry. This method of instruction is something very new in Germany and still in the experimental stage. The result they wish to accomplish is to bring out of German universities men who are not only filled with theories but at the same time know the practical side which is necessary to survive to-day in modern technical life.

The first volume handles in four chapters the metals, gold, silver, platinum and copper. Each chapter starts with the history of the metals, their distribution on the globe, the characteristics of the elements, their alloying properties and the different methods of producing and refining. Every chapter closes with cataloging literature on the subject. In the appendix practical mathematical examples are given to make the student familiar with some of the calculations in the metallurgical industry.

Of interest would be a bibliography of the most important patents covering the field.—F. TOBIAS.

The Elements of Ferrous Metallurgy. By JOSEPH L. ROSENHOLTZ. John Wiley & Sons, Inc., New York, 1930. Cloth, 6 × 9 inches, 248 pages. Price $3.00.

As stated in the preface this elementary text-book of ferrous metallurgy is intended as an introduction to the subject for students in technical high schools and colleges. As such it is good although we incline to the belief that for college students a more comprehensive treatment is advisable. An idea of the field covered is obtained from the chapter headings: Fundamentals, The Blast Furnace, Wrought Iron, The Cementation and Crucible Processes, The Bessemer Process, The Open-Hearth Process, The Electric Process, Defects in Ingots, The Foundry, The Iron-Carbon System, The Mechanical Treatment of Steel, The Heat Treatment of Carbon Steels, The Constitution of Carbon Steels, The Simple Steel Analysis, Alloy Steels, Cast Irons, Malleable Cast Iron. Considerable information is given.

A book of this character should give the student an idea of the relative economic importance of the various methods of steel making and steel products. This is not done. As much space is given to products of low tonnage as of high tonnage.—V. V. KENDALL.

Allgemeine Physik der Röntgenstrahlen. Handbuch der Experimental Physik. Vol. 24, Part 1. By F. KIRCHNER. Akademische Verlagsgesellschaft m. b. H., Leipzig, 1930. Cloth, 7 × 10 inches, 550 pages. Price 55 RM.

This new volume in the remarkably complete series of handbooks on experimental physics is unquestionably the most monumental work covering the general physics of X-rays which has ever been written. It is as nearly a complete account of all of the experimental facts dealing with X-radiation as such, as can possibly be imagined. The topics considered in order, after the general introduction covering the excitation of X-rays and their general properties, are: X-ray tubes, high tension equipment, the current-voltage characteristics of X-ray tubes, the intensity of rays emitted from X-ray tubes, electron emission by X-rays and the accompanying phenomena including the photoelectric emission, scattered electron emission, characteristic X-rays and characteristic electron emission, the secondary effects of X-rays upon matter through the action of photo and scattered electrons, the nature of scattering, the intensity of scattered rays, the theory of scattering of X-rays, wave length determination from diffraction and interference.

This great work can be thoroughly recommended to any reader who desires an exhaustive account of the experimental facts. One unusually excellent feature is the completeness with which the literature other than German is covered so that in no sense can a one-sided or prejudiced point of view be claimed.

Dr. Kirchner is one of the expert pioneers in X-ray science and his treatment is thoroughly authoritative. Some of the topics are somewhat difficult to find and on account of the nature of the presentation the treatment of a given topic is separated in various parts of the book, such as the Compton effect which is treated in 3 different places. However, these are points of minor importance when the nature of the book is considered. It is designed for a purely scientific group of expert readers. The mechanical features of the book are all that can be desired and although the price is fairly high, it is not by any means exorbitant for this treatise.—G. L. CLARK.

Iron and Steel Industry Handbook and Directory. Louis Cassier Co., Ltd., London, 1930. Paper, 6 × 9 inches, 234 pages. Price 10 sh.

This handbook covers the following subjects: Ores, fuels and refractories; blast furnace practice; foundry practice; wrought iron; steel-making practice; heat treatment and physical testing of iron and steel.

The following directories are also included in this volume: Iron & Steel Trades Associations and Societies, Scientific and Technical Institutions, Iron and Steel Foundries in Great Britain, and Blast Furnaces and Steelworks.—R. R.

Metal Industry Handbook and Directory. Louis Cassier Co., Ltd., London, 1930. Paper, 6 × 9 inches, 400 pages. (Not sold, given to subscribers to *Metal Industry*, London.)

This handbook is published annually by *Metal Industry* (London). In this edition the section "Properties of the Principal Metals," has been rewritten as regards aluminum and chromium, and mercury has been added. A similar revision was made in the section, "Properties of Some of the Rarer Metals," for molybdenum, thallium, titanium, tungsten, uranium, vanadium and zirconium, while cobalt has been included.

A table dealing with the fusing currents in amperes, for wires of copper, aluminum, tin and lead has been added. A number of new British Engineering Standards Association specifications have been added, and the section "Non-Ferrous Materials Specifications for Aircraft Parts" has been completely revised. A new section dealing with protective coatings other than electroplated ones is included.—R. R.

Metallurgie Agenda Dunod 1931. Dunod, Paris, 1931. Cloth, 4 × 6 inches, 497 pages. Price 23.50 Fr.

This pocket-size metallurgical handbook starts with a 1931 calendar with a patron saint for each day, and ends with 70 pages of the French laws on labor contracts, employment of women and children, etc., 30 pages of lists of books sold by Dunod, and a few blank pages of cross section paper.

In between are some 350 pages of descriptive, statistical and tabular matter of the sort usual in handbooks of this kind. A good deal of the data is not very well up to date. Some of it is interesting as showing the French point of view, but as a handbook, it is not very useful to the American metallurgist.—H. W. GILLETT.

Engineering Metallurgy. BY B. STOUGHTON & A. BUTTS. McGraw-Hill Book Co., second edition, 1930. Cloth, $6^1/_2 \times 9^1/_2$ inches, 498 pages. Price $4.00.

The second edition is enlarged by about 60 pages over the 1926 edition. The increase deals largely with welding, with additional data on alloy steels, and with a more complete treatment of physical metallurgy, especially in regard to heat-treatment. There has been considerable rearrangement of the subject matter on the basis of experience in its use as a college text.

The book has been brought up to date in several ways, partly by inclusion of new matter, and bringing statistics up to date, but especially by rephrasing or omission of various inaccurate or doubtful statements which marred the first edition.

As an example of the improvement in this regard, what amounted to an endorsement of various "accelerated" methods of endurance testing, has been eliminated. There are still a good many rather dogmatic statements that would require considerable elaboration to give the student a really true perspective. For instance, it is stated that sulphur in steel is harmful "in any form or in any amount over 0.01%."

The brevity of statement may sometimes lead the student astray. He will probably get the idea from the brief comment on nitriding that the process is regularly applied to plain carbon steels as an alternative to carburizing. And in such cases the references are scarcely complete enough to guide him to more specific information.

There is brief mention of cemented tungsten carbide, the Sperry detectoscope and the stethoscopic testing of welds. But the Aston process is not discussed, though the old puddling process gets brief mention.

From such mention of die casting as is made, the student will be led to place aluminum alloys in a rather more important position in comparison to zinc-base alloys than they really possess. The inclusion of a figure showing the granular resistor type of electric brass melting furnace would lead the reader to suppose that that type was still important commercially. One would gather that welding was a more important metallurgical process than the hot and cold rolling of steel, from the relative space devoted to them, and he would not grasp the fact that deep drawing of steel and the making of steel suited to deep drawing are as important as they are. The importance of the austenitic stainless steels is not adequately brought out, even for readers who are beginners.

But whether the reader agrees with the authors in the relative stress placed on different topics or not, he must admit that a vast amount of useful metallurgical information, including at least a smattering of most subjects anyone would want included in a general metallurgical course, has been packed together in the book. The scope of the subject matter is so well known to the many readers of the first edition that it is only necessary to say that the second edition is a real improvement and that the price is reasonable.—H. W. GILLETT.

Electroplating. BY SAMUEL FIELD & A. DUDLEY WEILL. Isaac Pitman & Sons, New York, 1930. Cloth, 5 × $7^1/_2$ inches, 205 pages. Price $2.00.

Field is head of the Chemistry Department, Northampton Polytechnic Institute, London, Weill is Technical Director of a London firm selling electroplating supplies. The illustrations are chiefly woodcuts of apparatus sold by this firm.

The discussion of the chemistry of electroplating is very elementary, but clear. Instead of giving a great variety of formulae for plating baths for the deposition of a given metal, one or two that have been found satisfactory are given, every opportunity being taken to urge the use of a simple solution.

A sane point of view is taken throughout. It is stated that while cadmium plating has attained extensive use, its value has to be established. Deposition of cadmium-silver alloys is classed as an unsolved problem.

The book is obviously written primarily for the small job plater. Automatic plating methods and large-scale methods in general are scarcely mentioned. Within its scope it is a useful little book.—H. W. GILLETT.

Jahresbericht der Abteilung für Metallchemie und Metallschutz. Reprint from Jahresbericht VIII. Verlag Chemie, Berlin, 1930. Paper, 6 × $9^1/_4$ inches, 54 pages. Price 6.40 RM.

In the study of corrosion theories, the Reichsanstalt has dealt with electrochemical methods and with Evans' aeration principle. An investigation on the corrosion of aluminum by hydrogen peroxide, to simulate an oxidizing attack, and on the inhibiting effect of sodium silicate, was carried on. Study was made of pairs of metals in contact, wholly immersed and of pairs each metal of which was partly immersed in sea water in separate beakers, but the solutions were connected by a tube and the metals by a wire. The potential between the metals is read from time to time. This work is in progress, and results will be reported later.

A table of potential measurements on various rust-resisting steels in various H_2SO_4-$CuSO_4$ solutions is given, which is claimed to class the steels more or less in the order of their rust-resistance. Current-time curves obtained from a cell made up of the steel under test against Cu in distilled water under an oxygen pressure of 120 mm. of water showed a knee in the curve when rusting starts. With the 18-8 type of steel, in properly rust-resistant condition, the initial current promptly falls to zero.

Work on paints for corrosion protection is reported, and brief comments made on various routine tests that were carried out in the laboratories on failed materials brought in for examination.—H. W. GILLETT.

Toward Civilization. By CHARLES E. BEARD. Longmans, Green & Co., New York, 1930. Cloth, 6 × 9 inches, 307 pages. Price $3.00.

Answering the challenge of a former symposium, "Whither Mankind," this volume presents the opinions of sixteen scientists and engineers constituting a survey of the technical tendencies of our modern age and a defense of machine civilization. The introduction and summary are by the editor. The essays are interesting in that they are written by such well-known persons as Robert A. Millikan, Lee deForest, Elmer A. Sperry and Lillian M. Gilbreth.—M. L. MOORMAN.

Die Strichprobe der Edelmetalle. By Karl Hradecky. Julius Springer, Vienna, 1930. Paper 6 × 9 inches, 83 pages. Price 7.5 RM.

This little volume is a treatise on the proximate analysis or assay of noble metals and their alloys by means of the "streak test," using the methods of mineralogy and microchemistry. There is first a discussion of the "streak" of alloys, the accuracy of this method, the determination of fineness, and the materials used in making the tests.

Then follows the testing of silver and gold alloys, including white golds. Platinum, palladium, and their alloys are also discussed.

Distinguishing genuine from imitation alloys occupies two pages.

Pages 67 to 81 present a systematic scheme for the examination of unknown noble metal alloys. The tables remind one of the outlines used in qualitative chemistry, mineralogy, etc.

Besides the methods of identifying and evaluating the various noble metals and their alloys, the author has given some information regarding the more recent uses of these alloys and their compositions.

This book will be of most use to dealers in secondary metals, but it should also be of value to analysts and assayers.—O. E. Harder.

Oxy-Acetylene Welding and Cutting. By Stuart Plumley. University Printing Company, Minneapolis, 1930. Cloth, 8 × 11 inches, 302 pages. Price $7.50.

Ability to write in a style that can be readily understood by the practical man and not be boring to the technical man or engineer, together with a thorough understanding of the subject is indeed a rare combination but we have it in this book. The author has been intimately associated with the oxy-acetylene industry for somewhat over twenty years, has learned much and has now put his knowledge in such shape that it may be readily assimilated by others without much effort.

The subject "Oxy-Acetylene Welding and Cutting" is treated much the same as a course in physics. The book being divided into twenty lessons corresponding to chapters and each lesson is followed by a job sheet equivalent to the physics experiment. At the end of each lesson there are also a number of questions which serve as a review. The book is a combination of text and manual, but may be read with profit by those interested in the art of oxy-acetylene welding and cutting but who do not have the facilities for performing the experiments given on the job sheets.

The first four lessons devoted to gases, details of construction, and use of torches, regulators, generators, etc., lays the foundation which will be found invaluable in a study of the subsequent chapters. This part of the book may be open to the criticism that the description and illustrations cover only one make of equipment but there is usually sufficient similarity between this equipment and the equipment of other manufacturers to permit applying the knowledge gained in the reading of these lessons to the apparatus of other manufacturers.

After covering in detail the proper setting up and use of the apparatus with due regard to the various elements of hazard the following lessons carry the reader through various methods of welding, brazing, and cutting of ferrous materials of a variety of shapes and sizes.

Recently the welding of pipe has been receiving much attention and the author very properly devotes two chapters to this important development. The first dealing with the smaller sizes of pipe, and use of templates, such as are used for steam and hot water heating, and the second applies to the larger sizes of pipes of which thousands of miles have been welded for the conveying of natural gas, oil, etc., from the oil fields to the larger centers of population.

The author has not confined himself to the oxy-acetylene welding of the ferrous metals but gives nearly as much space to the latest and approved methods of brazing steel and cast iron and the welding of a number of non-ferrous metals including aluminum, nickel, monel, copper, etc. and one lesson is given over to lead burning and soldering of automobile radiators.

As most welders are poor business men the author has sought to improve this condition by a lesson: "The Business Side of Welding" which contains instructions for the proper determination of costs and typical job cards and ledger sheets for recording pertinent facts in reference to work performed, materials used, etc.

The book ends with a short lesson on "Airplane Welding" and a job sheet covering the welding of tubing but a review would not be complete without calling special attention to an outstanding feature that is, the excellency of the numerous (over 400) line cuts and illustrations which aid greatly to a clearer understanding of the test.—J. J. Crowe.

High Speed Steel. By M. A. Grossman & E. C. Bain. John Wiley & Sons, New York, 1931. Cloth, 6 × 9 inches, 173 pages. Price $3.50.

Things generally appear complex only when we do not understand them. Grossman and Bain have taken much of the mystery out of high speed steel. By the assumptions that 1% of Cr is equivalent to 0.5% W, of V to 4.0% W, and of Mo to 1.3% W, that the carbide in high speed steel is Fe_4W_2C with some of the W substituted by the other elements, and that Co and the balance of the Cr goes into the ferrite, they set up a pseudo-binary ferrite–carbide system whose schematic diagram is entirely analogous to the Fe–C system. From the equivalent carbide content the behavior of high speed steel can, by means of this diagram, be explanied and remembered.

All through the book the behavior of high speed steel is described, and a very satisfying reason why given for every action. Ferrite, carbide and retained austenite, with hardening and tempering phenomena modified by the sluggishness due to the alloying elements in the ferrite and austenite, are brought to mind all through the book. The analogy with ordinary steel is so skillfully drawn and the differences so logically explained that the book is extremely easy to read.

The first half of the book, dealing with manufacture, is as satisfying as that dealing with composition and structure. Each step in melting and working is explained with clear comment on its bearing on the quality of the finished product. The book everywhere bears the earmarks of being written by those who know what they are talking about. Much data by other workers is incorporated to prove and clarify various points, but one gets the impression that the authors appreciate the bearing of such investigations on the general subject just as well as those who did the work.

Hence we have a book that fits all the pieces of the jig-saw puzzle together into a clear picture, rather than a kaleidoscope of jumbled facts and second-hand opinions such as we find in so many text-books and handbooks on technical subjects.

The authoritativeness with which the book is written, the clarity of understanding of the problem and the clarity of expression of the facts and principles makes it class very high. It is not only an extremely informative book, but it is a fine specimen of technical writing.—H. W. Gillett.

Der Temperguss. By Schüz-Stotz. Julius Springer Verlag, Berlin, 1930. Cloth, $6^1/_4 \times 9^1/_2$ inches, 390 pages. Price 39 RM.

This volume by two German metallurgists who have been active in the field of malleable iron, constitutes a welcome addition to the literature; first because it brings up-to-date in summarized form the available knowledge of the properties of malleable iron and second, because it presents the subject from a European viewpoint.

The subject matter is arranged in what may be considered an entirely orthodox form beginning with a history of the product which in turn is followed by a discussion of the scientific principles involved in its manufacture; following this a larger portion of the book is occupied by a discussion of the technology of malleable cast iron beginning with melting stock and ending with finishing operations. There is then a chapter dealing with various physical properties of the material and finally one covering production costs.

The entire group of subjects is authoritatively discussed, frequently by reference to other writers and so far as either necessary or desirable in a book of somewhat under four hundred pages, exhaustively treated

An American review of a German text must of necessity recognize certain differences of viewpoint which are fundamental where the author and reader are of different nationalities. The industrial conditions of two nations are never so nearly alike as to make it possible to write a text equally suitable for two or more countries. Since scientific principles and physical properties are independent of these variables the sections dealing with these subjects will very probably be of major interest to American students.

Since the authors deal in their volume with both black heart and white heart malleable, they have very naturally given space under both these headings to subject matter not usually found in the technical literature of the United States; thus they discuss at considerable length the processes of decarburization mainly in the light of Schenck's work on the iron-carbon-oxygen equilibria. The American reader may find this discussion of considerable value even though his own interests lie in suppressing decarburization rather than in favoring it.

In their discussion of graphitization the authors lay somewhat more stress on the principles of crystal growth than is commonly done in this country. This viewpoint is one to which we may well give consideration in this country to a greater extent than heretofore.

In the large section on technology the authors have sought to describe substantially all the methods and equipment used in German malleable plants, this has caused the inclusion of descriptions of processes which are either obsolete in the United States or otherwise impracticable. Thus the manufacture of crucible or convertor malleable is outside the interest of American readers and the space given to cupola malleable is disproportionately large from this country's viewpoint. For those who are operating this method in the United States, however, the book holds more information than has, to the writer's knoweldge, been elsewhere assembled on the subject of this particular method of production.

One subdivision of the section on technology may prove of very great interest in the United States; this is the author's treatment of the Brackelsberg furnace concerning which there is as yet no American experience in published form but which may be destined to fill a considerable field in this country.

The descriptions of foundry equipment include both European and American machinery and will be of relatively little importance to foundrymen in this country; they will find themselves already familiar with the equipment which originates in their own country and probably not very greatly interested in the European apparatus.

The chapter on production costs although bearing no relation to the corresponding costs in this country, is an illuminative comment on the economic systems of two important manufacturing nations.

As already stated the authors intend to cover both the black heart and white heart industry. As a matter of fact they apparently distinguish three kinds of malleable iron, "white fracture" which we call white heart; "black fracture" which we call black heart and an intermediate variety which they call black heart and which to us is "picture framed" iron. Since they do not carry this terminology throughout their entire discussion, it is not clear whether or not they recognize the latter classification as a mere defect of the black heart process. The authors are altogether cognizant of the difference in practice between the white heart and black heart industries using these words as understood by Americans and strive to emphasize this difference; there are, however, portions of the book where we who unconsciously think of all malleable iron as black heart, are likely to go astray unless we keep constantly before us the fact that the authors are speaking of both materials and we must be constantly on our guard to be sure from the context which one is referred to at any given point. The reviewer has found this difficulty particularly great in reading the discussion of the effect of silicon on the physical properties of the product.

Since there is no American literature of the white heart process, the present volume furnishes about the only complete and condensed source of information on that industry for those who may be interested therein.

The literary style is unusually concise and lucid as compared with most German works and the book is to be highly recommended to American readers possessing a working knowledge of that language. It will probably be most useful to those interested in general metallurgy or in the technical fundamentals of the manufacture of malleable castings. Those interested in cupola malleable or the Brackelsberg furnace will find much of importance to them while the reader of the strictly "practical" type whose interest is solely in manufacturing details will perhaps fail to benefit very greatly from its study.

One feature of a strictly practical nature should prove equally useful in all countries; this is the authors' discussion of the design of castings from the viewpoint of their economical and satisfactory production. The principles discussed may be of considerable value to engineers and pattern makers irrespective of nationality.—H. A. Schwartz.

Lukens Rolls Largest and Heaviest Plate

The Lukens Steel Company produced the largest and heaviest steel plate ever rolled up to the present time on Dec. 26th, on its 206-inch four-high reversing plate mill, the largest plate-rolling mill in the world.

The plate was reduced from a carbon steel ingot weighing approximately 92,130 lbs. produced in their open hearth. The sheared dimensions of the large plate are 195″ in width, $360^3/_4$″ in length and $2^3/_8$″ in thickness. It weighes approximately 48,200 lbs. Rolling mill operations were in charge of R. W. Simpson, Superintendent of Mills.

PATENT DEPARTMENT

An arrangement with Mr. W. M. Corse, Metallurgical Engineer, Washington, D. C., who operates an Engineering Information Service, enables us to publish a list of important patents from the United States, Canada, England, Germany, France, Switzerland, Denmark, Holland, Sweden, Norway and Italy. Copies of patents and translations will be supplied at reasonable cost. Patent searches made at minimum rates. Estimates cheerfully given. Information about this service may be secured by writing to the Patent Department, **Metals & Alloys**, 810 Eighteenth Street, Washington, D. C.

United States Patents

Note: Numbers of Reissue Patents are preceded by "Re."

Subject of Invention, Patentee, Patent No. and Filing Date.

Furnace conveyer. G. F. Beach, 1,782,335, original filed 4/8/26, divided and filed 6/1/27.

Method of welding copper boiler heads. A. H. Trageser & L. Hassinger, 1,782,373, 10/29/29.

Electric melting furnace. F. Linnhoff, 1,782,359, 2/7/29; Germany 2/11/28.

Recovering metals. U. A. Garred, 1,782,418, 4/8/27.

Heat-treating furnace. H. L. Waisner, 1,782,451, 11/7/27.

Welding machine. V. J. Chapman, 1,782,461, 1/24/28.

Annealing furnace. G. B. Shipley & H. Alinder, 1,782,481, 1/4/29.

Apparatus for heating a pickling solution. W. C. Siefert & G. W. Pawel, 1,782,482, 8/28/28.

Hydraulic press particularly for testing materials. A. J. Amsler, 1,782,595, 7/5/29; Germany 5/14/29.

Electrodeposition of metals. J. Hollins, 1,782,614, 1/22/29; Great Britain 2/25/28.

Electrolytic apparatus for refining aluminum and for like processes. P. L. Hulin, 1,782,616, 6/19/28; Germany 7/4/27.

Molding machine. T. O. Morris & J. J. Lawlor, 1,782,762, 6/1/27, renewed 2/8/30.

Treating copper ores preparatory to leaching. C. E. Carstens, 1,782,841, 8/17/25.

Casting machine. C. E. Hunter & De L. Lutz, 1,782,898, 4/30/30.

Apparatus for the electro deposition of iron. R. D. Pike, 1,782,909, 7/20/26.

Apparatus for casting zinc slabs and the like. D. M. Gray & J. J. Williams, 1,782,920, 10/27/28.

Purifying pig iron. K. Hofmann, 1,782,923, 5/9/29; Germany 5/25/28.

Apparatus for charging furnaces and the like. F. C. Biggert, Jr., 1,782,955, 1/7/27.

Rotary-hearth furnace. A. D. Dauch, 1,782,956, 3/20/26.

Means for rolling tubes. A. T. Keller, 1,782,968, 2/4/27.

Rod for use in arc welding or cutting. J. B. Green, 1,783,013, 2/10/27.

Process for the separation of cobalt and iron from solutions rich in iron as obtained by lixiviating roasted pyrites. N. E. Lenander, 1,783,046, 6/27/29; Germany 7/26/26.

Centrifugal casting machine. W. D. Moore & W. Morgan, 1,783,094, 6/4/28.

Ladle-tipping device for casting machines. W. Morgan, 1,783,128, 12/7/28.

Continuous soldering. M. Orenstein, 1,783,134, 2/9/29; Germany 2/15/28.

Alloy. (Cu–Ni–Zn). C. Philippossian, 1,783,139, 8/14/29; Switzerland 11/3/28.

Roller-mill guide. (Ni–Cr steel). M. Gorham, 1,783,148, 5/7/28.

Electric heating furnace. R. E. Talley, 1,783,155, 6/2/27.

Heat-treating apparatus. R. E. Talley, 1,783,156, 5/11/28, renewed 6/13/30.

Pickling crate. C. W. Haller, Re 17,882, (Original 1,711,054, filed 4/30/29) 3/26/30.

Method of making drums. W. A. Jones, 1,782,899, 3/19/26.

Method of coating metal surfaces. J. S. George & R. S. Sperry, 1,783,188, 12/23/26, original 8/11/25.

Process and apparatus for making bullets. S. Rousseau, 1,783,261, 9/3/26.

Furnace cooling by steam. H. F. Easter, 1,783,284, 3/9/28.

Mold. W. G. Goodwin, 1,783,285, 9/10/28.

Attachment for welding machines. E. W. Little, 1,783,337, 6/24/29.

Stereotype-plate-cooling apparatus. O. C. Roesen, 1,783,345, 3/5/27.

Method of electrically welding tubular articles. W. E. Crawford, 1,783,411, 5/8/29.

Blast furnace. J. P. Dovel, 1,783,416, 1/7/29, original 7/28/27.

Apparatus for coating wire. C. D. Johnson, 1,783,429, 6/22/29.

Process of making bearings. C. H. Landers, 1,783,438, 1/16/26.

Method of heating rolls. W. Schötteldreier, 1,783,524, 8/5/27, Germany 8/7/26.

Tube-transporting device. O. Bamberger, 1,783,555, 3/31/27.

Method of making electrically-welded tubing. J. W. Holt, 1,783,571, 4/18/27.

Apparatus for leaching and washing ores by the use of gas. A. B. Stevens, 1,783,591, 1/26/29.

Method of making cement-coated wire. J. B. Green, 1,783,613, 11/23/27.

Automatic soldering machine. J. E. Ferguson & W. A. Hoffman, 1,783,642, 11/2/28.

Etching precious metals. J. C. McFarland, 1,783,663, 6/22/28.

Manufacture of iron carbonyl. A. Mittasch & C. Müller, 1,783,744, 3/25/26, Germany 3/30/25.

Process of zone hardening steel articles. J. R. Adams, 1,783,764, 6/12/29.

Process of improving the resistance to corrosion of articles of magnesium and magnesium alloys. A. Beck & G. Siebel, 1,783,770, 1/30/29, Germany 2/2/28

Welding strip for golf shafts. H. C. Lagerblade, 1,783,802, 6/12/28.

Molding apparatus. F. J. Leuthner, 1,783,805, 8/2/29.

Apparatus for electrolytically depositing metal on metal tubes. F. G. Martin & W. Ramsey, 1,783,885, 9/29/27; Great Britain 4/22/27.

Soldering flux. H. C. Mougey, 1,783,925, 8/19/29.

Arc-welding apparatus. F. Lane, *et al.*, 1,784,015, 4/3/29.

Machine for welding. J. S. Newell, 1,784,024, 6/24/22.

Electrode Holder. (For welding electrodes.) J. H. Quisenberry, 1,784,075, 11/6/29.

Method of manufacturing electrically-welded vessels. R. Stresau, 1,784,080, 4/18/29.

Quenching tank. H. W. Fletcher, 1,784,095, 5/15/28.

Coating zinc and cadmium. A. Pacz, 1,784,106, 5/28/27.

Machine for babbitting sleeve bearings. C. H. Leis, 1,784,146, 12/28/29.

Compound mold for casting metal bodies. G. Bühler, 1,784,174, 10/29/28; Germany 11/4/27.

Annealing. J. R. Cain, 1,784,221, 8/2/27.

Core box. P. F. Devany, 1,784,225, 4/4/29.

Means for positioning mold pattern units. T. J. Flack, 1,784,345, 1/16/29.

Cooling means for castings. L. Förbus, 1,784,346, 12/24/29; Germany 1/2/29.

Water-cooled welding cable-joint construction. J. J. Paugh, 1,784,384, 4/29/29.

Continuous iron-temperature recorder. (*For molten iron.*) H. W. Dietert. 1,784,420, 7/12/26.

Rotary tempering furnace. E. Goerig, 1,784,427, 8/6/28; Germany 8/12/27.

Molding machine. W. Lewis, 1,784,457, 2/7/29.

Process for the recovery of the tin contained in the residues of tin-plate manufacture. J. Laley, 1,784,490, 4/3/28; France 1/23/28.

Method of cutting slots in metal. (*With a cutting jet.*) C. J. Coberly, 1,784,513, 7/10/29 (original 9/29/23).

Coating metal articles. F. M. Becket, 1,784,570, 10/29/28.

Forming die. R. J. Curtis, 1,784,579, 10/10/28.

Casting under pressure. S. Junghans, 1,784,600, 7/24/28; Germany 12/20/27.

Method of making crucibles. W. F. Whitney, 1,784,647, 11/3/26.

Apparatus for agglomerating and roasting minerals. A. de Samsonow, 1,784,658, 12/23/27; Belgium 1/4/27.

Electric furnace. A. Imbery, 1,784,670, 10/8/28; Great Britain 10/10/27.

Automatic charging of electric furnaces. P. L. J. Miguet, 1,784,699, 3/20/29; France 12/6/28.

Apparatus for preparing casting molds. B. L. M. van der Lande & G. Komen, 1,784,714, 3/26/28; Netherlands 8/27/27.

Rolling mill. K. Gruber, 1,784,791, 1/27/28; Germany 6/14/27.

Silicon steel. V. B. Browne, 1,784,811, 2/13/30.

Furnace and conveyer therefor. R. S. Cochran, 1,784,812, 4/23/28.

Magnetic material. G. W. Elmen, 1,784,827, 6/15/28.

Method of strain hardening manganese steel. F. A. Fahrenwald, 1,784,865, 12/13/26.

Method of strain hardening steel. F. A. Fahrenwald, 1,784,866, 3/24/27.

Method and apparatus for shipping metal. R. T. Romine, 1,784,909, 1/23/30.

Process of welding drills. F. O. Hoagland, 1,784,932, 2/1/28.

Process of producing chromic acid. M. J. Udy, 1,784,950, 12/16/27.

Cutting and welding torch. A. F. Jenkins, 1,784,964, 9/7/28.

Tank for chromium plating. C. R. Gleason, 1,784,987, 6/3/27, renewed 3/14/30.

Molding machine. T. O. Morris & J. J. Lawlor, 1,784,995, 3/12/29.

Metallurgical process. (*Treatment of molten Ni-Fe alloy.*) J. H. White, 1,785,060, 12/15/26.

Soldering flux. H. B. Dykstra, 1,785,115, 5/7/30.

Zinc-chloride-base flux. G. Lutz, 1,785,131, 12/26/29.

Soldering. H. S. McQuaid, 1,785,134, 12/26/29.

Flux for soft soldering. H. S. McQuaid, 1,785,135, 12/26/29.

Composite-metal article and method of making the same. C. W. Miller & R. E. Bissell, 1,785,137, 12/30/27.

Process of producing metallic cadmium from cadmium-containing material. H. H. Monroe, 1,785,139, 5/18/28.

Zinc-chloride-base flux. E. A. Taylor, 1,785,155, 12/26/29.

Multiple-stereotype-plate-casting machine. H. A. W. Wood, 1,785,164, 4/9/27.

Soldering flux. H. J. Barrett, 1,785,173, 5/7/30.

Flux for use in soldering. H. P. Corson, 1,785,180, 12/26/29.

Soft soldering flux. H. P. Corson, 1,785,181, 12/26/29.

Manufacture of low-carbon chrome steel. F. O. Kichline, 1,785,199, 4/20/26.

Removal of lead coatings from metallic articles. K. B. Bowman, 1,785,245, 10/8/29.

Magnetic material. W. F. Brandsma, *et al.*, 1,785,246, 8/1/28; Netherlands 7/19/27.

Recovery of metallic elements and alloys. H. M. Burkey & D. L. Ogden, 1,785,247, 8/15/28.

Process for producing lamelliform metal powders. E. Podszus, 1,785,283, 9/6/23; Germany 9/12/22.

Hot-metal car. C. P. Astrom, 1,785,292, 4/23/29.

Tin pot. J. T. McQuiston, 1,785,322, 1/12/27.

Alloy. (*Cu-Zn-Mn.*) J. N. White, 1,785,372, 11/12/29.

Process for controlling electroplating. R. J. Piersol, 1,785,389, 1/14/29.

Combined ore-reducing and hydro-carbon-refining apparatus. W. H. Smith, 1,785,427, 12/27/26.

Process of reducing ore and converting hydrocarbons. W. H. Smith, 1,785,428, 4/4/27.

Method of making plated shot. E. Pugsley, 1,785,493, 1/9/29.

Apparatus for desulphurizing cast iron. L. W. Spring, 1,785,503, 6/22/29 (original 6/16/28).

Solvent inhibitor for the acid treatment of metals. W. S. Calcott & I. E. Lee, 1,785,513, 4/17/29.

Open-hearth regenerative furnace. J. O. Griggs, 1,785,549, 4/1/29.

Manufacture or lining of pipes by centrifugal action. E. S. Hume, 1,785,586, 12/27/28; Australia 1/10/28.

Electrode joint. C. Kuhlmann, 1,785,587, 6/7/28; Germany 7/2/27.

Preliminary treatment of metal plates for the production of printing plates. F. Ullmann, 1,785,606, 3/7/27; Germany 3/10/26.

Metal pot for line-casting machines. L. W. Willis, 1,785,607, 7/5/29.

Apparatus for jarring ingot molds. L. Young, 1,785,757, 4/19/29.

Tinning apparatus. H. W. Bundy, 1,785,762, 12/4/25.

Plastic heat-treated aluminum alloy. N. V. Hybinette, 1,785,774, 5/18/29.

Pocketed welding, brazing, and hard-soldering rod. O. M. Krembs, 1,785,778, 3/11/29.

Method of rolling and annealing sheet metal. A. Paterson, 1,785,786, 3/26/28, renewed 5/14/30.
Crate for metallic sheets. J. R. Freeze, 1,785,863, 8/21/29.
Mold for casting metals. W. F. Eppensteiner, 1,785,941, 3/6/29.
Method of and apparatus for rolling sheet metal. J. R. Speer & F. H. Moyer, 1,785,986, 7/6/28.
Wire-testing machine. C. C. Sunderland, 1,786,138, 9/17/28.
Molding machine. R. F. Ringle, 1,786,171, 5/29/29.
Apparatus for high-temperature treatment of ores and other substances. M. Fourment, 1,786,202, 12/22/26; France 2/2/26.
Flask-handling device. S. D. Moxley, 1,786,218, 10/7/27.
Port construction and gas burner for open-hearth furnaces. G. F. Downs & H. F. Miller, Jr., 1,786,293, 11/4/20.
Rolling-mill housing. J. R. George, 1,786,296, 3/28/28.
Process of rolling alloy steel. H. M. Givens, *et al.*, 1,786,297, 11/20/29.
Extracting of tin from ores or materials containing tin. E. A. Ashcroft, 1,786,386, 5/4/28; Great Britain 6/24/27.
Method of producing ferromolybdenum and ferrotungsten. P. Schwarzkopf, 1,786,393, 4/29/29; Germany 5/22/26.
Protective metal coating and process and apparatus for producing the same. C. G. Fink & C. H. Eldridge, 1,786,398, 8/12/25, renewed 5/6/30.
Electric furnace. M. Unger, 1,786,322, 6/1/28.
Process for treating mill band saws. O. Muehlen, 1,786,444, 6/17/27.
Recrystallized refractory composition. T. S. Curtis, 1,786,482, 6/26/28.
Apparatus for and art of treatment of metal work. H. Rosenberg, 1,786,508, 6/20/29.
Electroplating apparatus. K. Baranowski, 1,786,592, 10/29/28; Great Britain 12/21/27.
Casting machine for battery grids. D. Pepper, 1,786,629, 6/4/29.
Molding machine. T. O. Morris & J. J. Lawlor, 1,786,672, 7/8/29.
Reduction of metal by rolling mills. A. Paterson, 1,786,775, 10/27/28.
Rolling mills. J. B. Tytus, 1,786,793, 5/20/25.
Process of refining iron and steel. S. Westberg, 1,786,806, 10/21/24.
Roll-polishing device. J. R. Byrum, *et al.*, 1,786,820, 3/24/28.
Furnace construction. H. Daum, 1,786,829, 7/10/28.
Rolling metal. D. Eppelsheimer, 1,786,834, 12/10/27.
Process for the separation and purification of metals and metallic alloys. (Sb from Pb alloys.) A. Hanak, 1,786,908, 8/8/28.
Method of operating carburizing apparatus. R. Kaier, 1,786,951, 8/18/28 (original 10/3/27).
Reduction of metals from ores. J. W. Hornsey, 1,786,999, 9/27/28 (original 11/25/25).
Seam-welding machine. W. H. Gibb, 1,787,039, 6/28/28.
Welding process. H. G. Spilsbury, 1,787,056, 8/27/27.
Welding machine. G. S. Lewis, 1,787,115, 5/18/28.
Method for making pure alumina by electrothermal reduction of the impurities in alumina-containing raw materials. H. Siegens, 1,787,124, 12/22/27; Germany 6/1/26.
Process of forming iron foils. J. R. Cain, 1,787,139, 6/11/26.
Galvanizing machine. J. Carroll, 1,787,141, 11/2/28.
Method of shaping edges for fusion welding. H. J. Grow, 1,787,247, 11/30/29.
Method of making sheet-metal bearings. W. H. Klocke, 1,787,255, 11/1/28, renewed 5/29/30.
Process of reducing ores. H. Wittek, 1,787,348, 12/1/26; Germany 7/26/26.
Steel alloy insensible to hot gases and vapors. B. Strauss, 1,787,403, 4/5/29; Germany 9/21/28.
Electric welding. J. F. Lawson, 1,786,759, 6/24/27.
Furnace. W. F. Detwiler, 1,787,307, 3/9/29.

Austrian Patents

Subject of Invention, Patentee, Patent No. and Date of Beginning of Term of Patent.

Process for making high-strength cast iron. K. Emmel, 120,382 (Addition to 113,306), 7/15/30.
Oxidation - and corrosion-resistant forgeable chrome-nickel steels. Poldihütte, 120,668, 5/15/27.
Process for separating alloys into their crystalline constituents. T. Kittl, 120,383, 7/15/30.
Process for making self-baking electrodes and for renewing them in service. Gebr. Siemens & Co., 120,380, 7/15/30.
Anode for the electrolytic recovering of pure aluminum from crude aluminum, aluminum alloys and the like. Aluminium Industrie Akt.-Ges., 120,386, 7/15/30.
Process for chromium-plating conducting objects. Soc. Nouvelle de l'Orfevrerie d'Ercuis, 120,388, 7/15/30.
Process for forming metal deposits. O. Lefnaer, 120,400, 7/15/30.
Etching machine. Hoh & Hahne, 120,379, 7/15/30.
Process for coating delicate goods with metals by electrode sputtering in a vacuum, with simultaneous cooling. Ges. für Elektrodenzerstäubung m. b. H., 120,656, 7/15/30.
Process and mandrel for pressing metal tubing. K. Hildebrand & O. Pflanzer, 120,359, 7/15/30.
Process for improving the mechanical properties, especially the compressive yield point, of products made of magnesium and magnesium alloys. I. G. Farbenindustrie Akt.-Ges., 120,375, 7/15/30.
Transformer for electric welding installations. Ateliers de Construction Electriques de Charleroi S.A., 120,339, 7/15/30.
Device for regulating the rate of feed of the wire in arc welding machines. A. E. G. Union Elektricitäts Ges., 120,358, 7/15/30.
Flexible-shaft drive for tool holders guided by a template, particularly those of autogenous welding and cutting machines. A. Schmidt, 120,367, 7/15/30.
Fuel tank for soldering torches and the like. M. J. R. Metallwarenfabrik Josef Rosenthal Akt.-Ges., 120,371, 7/15/30.
Arrangements of the welds in the welding of flanges to rolled-metal walls of tanks and the like. Akt.-Ges. vorm. Skodawerk in Pilsen, 120,373, 7/15/30.
Process for making hollow drill steels and the like by rolling or forging hollow billets. F. Hatlanek, 120,344, 7/15/30.
Process for pressing irregularly shaped objects, particularly parts of auto bodies. Edward G. Budd Mfg. Co., 120,346, 7/15/30.
Process for making sections of uniform wall thickness from strips of sheet metal. I. G. Farbenindustrie Akt.-Ges., 120,361, 7/15/30.
Process and apparatus for making rails with hardened heads. Vereinigte Stahlwerke Akt.-Ges., 120,342, 7/15/30.

British Patents

Note: When the date applied for differs from the date on which the application was lodged at the British Patent Office, the former date is given, followed by *.

Subject of Invention, Patentee, Patent No. and Filing Date.

Electrical induction apparatus applicable to resistance welding. J. Archard, 338,172, 11/26/28*.
Tuyères for blast furnaces. E. Pohl, *et al.*, 338,130, 5/10/29.
Manufacture of metallic sheet, strip, or wire. S. O. Cowper-Coles, 338,173, 5/16/29.
Electric furnaces. Carborundum Co., 338,131, 12/7/28*.
Device for the hot stamping of bolts and rivets of large dimensions. P. T. Kikot, 338,148, 8/8/29.
Extraction of tin from ores, alloys, scrap, or the like. Soc. D'Electro-Chimie, D'Electro-Métallurgique, et des Aciéries Electriques D'Ugine, 338,149, 6/22/29*.
Refining of iron or steel. F. Krupp Akt.-Ges., Friedrich-Alfred-Hütte, 317,373, 8/14/28*.
Producing colored protective layers on the surface of aluminum-alloys, and articles made of aluminum alloys. A. Pacz, 338,204, 8/16/29.
Art of protectively treating metals. A. Arent, 338,221, 8/20/29.
Treatment of air-blast for furnaces. G. Malyoth, 338,244, 8/28/29.
Method of heat-treating nitrogenized alloy steel articles. R. Sergeson, 338,315, 10/18/29.
Electrodes of electric furnaces and electrolytic vats. P. Girod, 338,371, 8/27/29*.
Manufacture of iron and iron-nickel and iron-silicon alloys. Associated Electrical Industries, Ltd. 338,409, 1/18/29*
Apparatus for drawing metal tubes. Soc. M. Bassot et Cie., 338,415, 1/24/29*.
Method of manufacturing crank shafts or cranks. Vereinigte Stahlwerke A.-G. 338,439, 3/15/29*.
Alumino-thermic process for the generation of highest temperatures. E. Blümner, 338,468, 3/11/30.
Coating especially adapted for filming tin and like foil. Staniofabrik Burgdof A.-G., 338,340, 10/9/29*.
Process and apparatus for the electrodeposition of metals. S. O. Cowper-Coles, 338,487, 5/15/29*.
Electrolytic production or separation of tin. Siemens & Halske Akt.-Ges., 338,488, 5/16/29.
Blow-pipe-burner machines for cutting or welding metals. Akt.-Ges. für Tiefbohrtechnik und Maschinenbau vorm. Trauzl & Co., 312,193, 5/19/28*.
Journal bearing and method of manufacture. Kalif Corp., 338,505, 7/19/29.
Method of and means for annealing crystalline substances. E. G. Herbert, 338,511, 8/16/29.
Production of metals and apparatus for use in the same. J. E. Fletcher, 338,-535, 8/19/29.
Process and apparatus and processes for the treatment of ores or materials containing copper and/or nickel. E. A. Ashcroft, 338,556, 8/20/29.
Manufacture of pointed tubular metal articles. S. J. Everett, 338,592, 8/22/29.
Steel alloys. Nitralloy, Ltd., 338,655, 10/9/28*.
Non-ferrous alloys. G. H. Whiteman, and Imperial Chemical Industries, Ltd., 338,676, 10/14/29.
Making or re-melting alloys of aluminum and iron. British & Dominions Feralloy, Ltd., & J. W. Bampfylde, 338,688, 10/21/29.
Method of rolling down metal bands and sheets in the hot state to thin gauges. L. E. Broemel, 338,771, 12/18/29.
Regenerative furnaces. O. Reiner, 338,788, 1/10/29*.
Machines for casting stereotype plates. C. Winkler, 338,802, 1/23/30.
Electro-deposition of metals. S. O. Cowper-Coles, 338,540, 5/15/29*.
Method of treating tin-containing material. Mitsubishi Kogyo Kabushik. Kaisha, 316,177, 7/24/28*.
Heat-treatment for hardened steel. Vereinigte Stahlwerke A.-G., 314,056, 6/22/28*.
Changing a simple element into other simple elements of lower atomic weight. P. de Prat, 314,427, 6/27/28*.
Aluminum alloy. H. J. Garrard, 338,923, 5/30/29.
Treatment of cast iron. Link-Belt Co., 338,924, 5/31/29.
Ferrous metal or alloy. Link-Belt Co., 338,925, 5/31/29.
Heating furnaces suitable for metallurgical purposes. R. A. Hadfield & R. J. Sarjant, 338,893, 6/26/29.
Manufacture and production of aluminum. I. G. Farbenindustrie A.-G., 338,668, 7/4/29.
Apparatus for extruding and coiling rods. Scovill Mfg. Co., 338,948, 8/22/29.
Electrodes for electrolytic purposes. Electro-Chemische Industrie, 318,154, 8/23/29.
Blast roasting or sintering of ores and metallurgical materials. National Processes, Ltd., & T. B. Gyles, 338,886, 8/27/29.
Heat-treatment of alloy irons and steels. P. R. Kuehnrich & Darwins Ltd., 338,912, 8/22/29.
Manufacture of steel having good machining properties. F. Borggräfe, 318,177, 8/29/28*.
Methods of lining pipes, more particularly the exhaust-pipes of gas engines. Gutehoffnungshütte Oberhausen A.-G., 318,179, 8/29/28*.
Pouring-trough for centrifugal metal-casting apparatus. Ferric Engineering Co., 339,017, 11/7/28*.
Die-casting machines. Krone-Sebek Die Casting & Manufacturing Co., 339,023, 9/19/29.
Blow-pipes, for cutting and welding, of the liquid-fuel-fed type. G. Lotzow, *et al.*, 339,037, 10/3/29.
Process of and machines for casting metal pipes. Soc. Anon. des Hauts Fourneaux et Fonderies de Pont-à-Mousson, 339,095, 12/20/28*.
Method of and heating-apparatus for the heat treatment of wire and stip prior to galvanizing or other form of surface treatment. L. D. Whitehead, 339,-155, 1/6/30.
Welding. Budd Wheel Co., 339,228, 4/25/29*.
Simultaneous reduction of ores and conversion of carbonaceous materials into hydrocarbons of low boiling point. J. L. Fohlen, 339,276, 7/25/29.
Production of continuously-burning, parallel-arranged electric arcs. I. G. Farbenindustrie Akt.-Ges., 339,329, 7/29/29.
Applying a metal coating to aluminum by galvanic means. M. K. De Trairup, 339,339, 9/3/29.
Manufacture of iron pans for zinc baths. N. O. Midderman, 339,384, 9/20/29.

Method of and apparatus for making articles by electrolytic deposition of galvanoplastic metal. G. Rosenqvist, 339,428, 10/24/29.
Aluminum alloy. O. Kamps, 339,469, 11/25/29.
Preparation of magnesium by electrolysis. Dow Chemical Co., 339,504, 12/17/29.
Heat treatment of manganese steel. Taylor-Wharton Iron & Steel Co., 339,-521, 12/31/29.
Welding of metal pipes or tubes. H. Mayweg, 339,570, 3/10/30.
Treatment of a molten mass of metal or alloy, particularly a mass of molten steel in a ladle. F. Krupp Akt.-Ges., 339,579 (Addition to 312,063), 4/30/29*.

Canadian Patents

Subject of Invention, Patentee, Patent No. and Filing Date.

Reinforcement of welded joints. Executors of W. J. Gamble, 305,755, 11/2/29.
Refractory materials for furnace linings. G. M. Carrie & A. C. Halferdahl, 305,757, 12/22/28.
Flux for soldering. J. H. Gravell, 305,783, 11/18/30.
Vibrating apparatus for removing patterns and castings from sand molds. C. B. Pike, 305,807, 12/17/28.
Protection of metal bodies from corrosive agencies. P. F. Schade, 305,812, 2/21/30.
Aluminum solder. C. F. W. Schwarz, 305,814, 7/13/29.
Method of treating solid materials (ores) with gases. F. M. Wiberg, 305,827, 9/18/29.
Process of electrodepositing metals of the platinum group. Baker & Co., Inc., 305,840, 5/15/30.
Electrodeposition of platinum metals. Baker & Co., Inc., 305,841, 5/15/30,
Hard metal composition. The Canadian General Electric Co., Ltd., 305,847, 3/7/28.
Manufacture of refractory articles. The Carborundum Co., 305,865, 11/24/28.
Process of reducing iron ores. The Davis Steel Process Corp., 305,871, 7/11/29.
Process of producing iron or steel directly from the ore. Same patentee, 305,-872, 7/11/29.
Rust-proofing material. The Parker Rust Proof Co., 305,928, 2/24/30.
Treatment of beryllium. Skinner & Sherman, Inc., 305,937, 10/22/29.
Mill roll. W. C. Oberg, 305,963, 1/2/29.
Ingot stripping mechanism. The Alliance Machine Co., 306,049, 6/14/29.
Method of strain hardening steel. The American Manganese Steel Co., 306,051, 4/4/28.
Digging tool with hard metal cores. Same patentee, 306,052, 11/14/29.
Steel (pearlitic manganese steel). The American Steel Foundries, 306,054 & 306,055, 8/28/29.
Process of refining lead-bismuth alloys. The Consolidated Mining & Smelting Co. of Canada, Ltd., 306,082, 5/9/29.
Process of recovering metals from the slimes of electrolytic lead refining operations. Same patentee, 306,083, 5/28/29.
Metal bar cooling bed. The Mesta Machine Co., 306,111, 6/23/30.
Process of plating brass with chromium. The Metals Protection Corp., 306,112, 9/20/29.
Method of heat treating rods, etc. F. A. Fahrenwald, 306,165, 6/27/29.
Bearing metal (lead-alkaline earth alloy). W. Mathesius & M. W. Neufeld, 306,173, 3/12/27.
Production of steel abrasive materials. S. D. Layton, 306,226, 2/19/30.
Apparatus for casting light metals. E. Roth, 306,246, 11/26/29.
Anti-corrosive process for metals. (Deposition of antimony.) The Arthur Arent Laboratories, Inc., 306,271, 5/27/29.
Refractory metal body. The Canadian Westinghouse Co., Ltd., 306,285, 4/30/27.
Process of producing rare metals. Same patentee, 306,286, 7/30/27.
Resistance alloy (chromium-tungsten). Same patentee, 306,287, 9/9/27.
Soldering machine. Same patentee, 306,292, 6/22/29.
Production of refractory articles. Same patentee, 306,297, 11/27/29.
Method of refining copper. The Western Electric Co., Inc., 306,406, 2/7/29,
Chaplet. The Fanner Mfg. Co., 306,425, 5/22/30.
Foundry molding machine. The British Insulated Cables, Ltd., 306,528, 9/24/29.
Method of treating tungsten filaments. The Canadian Westinghouse Co., Ltd., 306,544, 4/30/27.
Cast iron converter. La Carbonisation Soc. Générale d'Exploitation des Carbones, 306,579, 1/5/29.
Ferrous metal. Link-Belt Ltd., 306,582, 3/22/29.
Lead alloy. (Aged alloy containing 0.1% Ca.) The Western Electric Co., Inc., 306,610, 4/22/29.

Danish Patents

Subject of Invention, Patentee, Patent No. and Filing Date.

Process for changing the shape of hollow metal bodies and for improving the structure of the metal. United States Cast Iron Pipe & Foundry Co., 43,332, 6/22/29.
Tilting furnace. Siemens & Halske Akt.-Ges., 43,358, 1/10/30.
Process for making pipe by electric butt welding. F. A. Frisch, *et al.*, 43,372, 1/14/29.
Process for recovering zinc and other volatile metals from their ores. H. E. Coley, 43,375, 1/10/29.

French Patents

Subject of Invention, Patentee, Patent No. and Filing Date.

Machine for bending iron sections. A. François & H. J. Cousin, 696,750, 6/6/30.
Machine for bending iron bars. H. Binet, 697,083, 6/4/30.
Improvements to methods of producing and refining ferrous metals. Syndicat des Laitiers et Scories, 696,779, 9/11/29.
Process for roasting and pyrogenetic agglomeration of concentrated pyrite and sulfidic iron materials. A. Folliet & N. Sainderichin, 697,006, 5/26/30.
Alloy steels and objects which are resistant to corrosion by particularly active solutions. Fried. Krupp Akt.-Ges. & Heinrich Koppers Akt.-Ges., 697,053, 6/2/30.
Improvements to methods for producing sponge iron. I. Rennerfelt & I. C. S. G. Bohm, 697,058, 6/3/30.
Process for annealing steel. H. Hanemann, Addition 37,678 (2nd addition to 667,217 filed 1/10/29), 5/23/30.
Improvements to hard metallic compositions and to processes for making them. Cie. Française pour l'Exploitation des Procédés Thomson-Houston, Addition 37,695 (3rd addition to 654,210 filed 4/4/28), 9/26/29.
Process for refining nickel, copper and copper-nickel alloys. H. J. M. E. Clerc, Addition 37,713 (2nd addition to 669,109 filed 6/1/28), 5/28/29.
Method of preheating scrap iron for welding. A. Dossmann, 696,679, 6/5/30.
Gasoline soldering torch. S. Milioni, 696,720, 6/6/30.
Process and machine for making metal tubes with ends thickened by upsetting. Mannesmannröhren Werke, 696,836, 6/7/30.
Bar for the production of heat treated objects. A. B. Svenska Kullagerfabriken, 696,855, 6/7/30.
Casting machine. R. Rondel & G. Iochum, 696,976, 5/17/30.
Improvements to processes and to equipment for making wrought iron. A. M. Byers Co., 697,098, 6/4/30.
Methods and device for making large chain links by electric welding. Henri Davaine Fils & Co., 697,125, 6/6/30.
Improvements to electric furnaces. Wild Barfield Electric Furnaces, Ltd., 696,853, 6/7/30.
Improvements to electrolytic apparatus. A. E. Knowles, 697,043, 5/31/30.
Improvements to the method of propagating electrothermic reactions. Buffalo Electric Furnace Corp., 697,108, 6/5/30.
Overload safety device for rolling mills, presses and the like. E. Svatos, 697,-365, 6/26/29.
Process for making tools. Fried. Krupp Akt.-Ges., 697187, 6/11/30.
Wire-drawing die. Vereinigte Stahlwerke Akt.-Ges., 697,351, 6/13/30.
Process for improving the mechanical properties, for example the yield point and fatigue bending strength of austenitic iron-chromium-nickel-carbon alloys. Fried. Krupp Akt.-Ges., 697,188, 6/11/30.
Treatment of zinciferous materials containing cadmium. The New Jersey Zinc Co., 697,217, 6/11/30.
Improvements in the treatment of slag. Det Norske A/S for Elektrokemisk Industri, 697,403.
Means for cementing cast metal scrap. A. Gourgaud, addition 37,740 (1st addition to 664,565 filed 11/22/28), 11/5/29.
Process for forming a metallic coating on any kind of object. H. Mayr, 697,211, 6/11/30.
Process for producing metals having a corrosion-resistant layer. Vereinigte Stahlwerke Akt.-Ges., 697,297, 6/12/30.
Device for extracting metal pipes and the like. P. Dunsheath, 697,306, 6/-13/30.
Process for metallizing objects of organic origin by metallic vaporization. K. Richter, 697,308, 6/13/30.
Process for forming thin coatings on any kind of object. K. Richter, 697,309, 6/13/30.
Improvements to rotary furnaces. R. P. E. Roman & T. Lafitte, 697,373, 4/23/30.
Improvements to special compositions for making tools and the like. Firth Sterling Steel Co., 697,611, 6/18/30.
Improvements to processes and to means for rectifying surfaces such as those of sheet metal and the like. Bleriot Aeronautique, 697,619, 6/18/30.
Process for treating rails or other massive objects. Bethlehem Steel Co., 697,529, 6/17/30.
Improvements to ingot molds. Firth Sterling Steel Co., 697,552, 6/17/30.
Improvements to processes for reducing oxides and other compounds of iron. M. Amoroso & Società Anonima Metalfer, 697,626, 6/18/30.
Improvements to processes for rolling sheet metal. The American Rolling Mill Co., 697,664, 6/19/30.
Improvements to processes for working metallic objects. Firth Sterling Steel Co., 697,670, 6/19/30.
Process for improving the resistant qualities of magnesium alloys. I. G. Farbenindustrie Akt.-Ges., 697,747, 6/21/30.
Fire-resistant and corrosion-resistant alloy steel. T. Czepl, 697,801, 6/23/30.
Rolling mill drive. A. Schopf, 697,805, 6/23/30.
Process for making high strength steels. M. Stern Akt.-Ges., 697,811, 6/23/30.
Improvements to water-jacketed shaft furnaces. Soc. An. Le Nickel, 697,962, 9/30/29.
Device for placing the work in the dies of horizontal forging machines. Maschinenfabrik Hasenclever Akt.-Ges., 697,438, 6/16/30.
Process and devices for making sheet metal longerons. Boisvert & Aran, 697,-520, 6/16/30.
Improvements to welding machines. Ford Motor Co., Ltd., 697,583, 6/17/30.
Cast iron tappets and the like and process for making them. Ford Motor Co, Ltd., 697,631, 6/18/30.
Method of joining metals which are very hard to cut. R. Braun, 697,655. 6/19/30.
Bolts, wrist-pins, and the like obtained by swaging tubing. R. Charbonnier, 697,687, 6/19/30.
Improvements to stamping dies. Edward G. Budd Mfg. Co., 697,754, 6/21/-30.
Apparatus for examining crystalline substances with the aid of X-rays. N. V. Philips' Gloeilampenfabrieken, 697,731, 6/20/30.
Improvements to anodes. Udylite Process Co., 697,728 & 697,729, 6/20/30.
Muffle furnace. M. Ducroquet & R. Gillain, 697,610, 6/18/30.
Improvements to tunnel furnaces. Woodall Duckham, Ltd. & A. M. Duckham, 697,639, 6/18/30.

German Patents

Subject of Invention, Patentee, Patent No. and Filing Date.

Process for making weld iron. A. Dossmann, 513,732, 4/27/28.
Gas-heated, doorless hardening furnace with vertically or horizontally disposed preheating, hardening and tempering chambers. E. Reimann, 513,601, 6/15/28.
Process for making cores of hard iron powder. Weitverkehrskabel G. m. b. H., 513,761, 12/24/27.
Heat-resistant coils and windings. I. G. Farbenindustrie Akt.-Ges., 513,689, 12/29/28.
Process for making electric heating elements. Voigt & Haeffner Akt.-Ges., 513,607, 9/6/27.
Means for interchanging heating-element holders in electric furnaces. E. F. Russ, 513,762, 8/5/27.
Two-piece chaplet. E. Sonnet, 513,737, 5/5/27.
Process for producing non-porous castings of alloys containing copper by the addition of a copper compound. A. Kirchhof, 513,738, 4/16/24.

Decomposing stanniferous raw material. W. Poetsch, 513,697, 8/15/28.

Lead-base bearing metal. W. Mathesius & M. W. Neufeld, 513,623 (Addition to 441,071), 4/27/26.

Process for plating objects with chromium. Metals Protection Corp, 513,742, 7/3/27; U. S. 9/9/26.

Device for cutting or welding metallic bodies with curved surface and varying thickness. Akt.-Ges für Tiefbohrtechnik u. Maschinenbau vorm. Trauzl & Co., & F. L. Müller, 513,715, 8/6/29; Austria 7/13/29.

Method of finishing hammer- or press-forged shafts. E. Kamp, 514,148, 6/27/28.

Mandrel lock for tubing mills. Maschinenfabrik Meer Akt.-Ges., 514,243, 3/8/29.

Roll setting device for cold-rolling mills. Demag Akt.-Ges., 513,989, 8/12/28,

Rolling mill for making metal balls out of heated pre-pressed blanks. O. Rump, 513,939, 4/11/29.

Electric annealing furnace. Siemens-Schuckertwerke Akt.-Ges., 514,235, 7/1/28.

Method of operating a heat treating furnace fired either with gas or coal dust as desired. T. Wuppermann, 514,017, 5/9/28.

Leads from the transformer to the electrodes of three-phase furnaces. Siemens-Schuckertwerke Akt.-Ges., 514,193, 7/24/28.

Process and machine for making pipes, cylinders and the like by centrifugal casting. Ostermann & Flüs Akt.-Ges., 514,201, 5/27/28.

Process for making hollow bodies by centrifugal casting in green sand molds. S. A. des Hauts-Fourneaux & Fonderies de Pont-à-Mousson, 514,153, 9/13/25.

Water-cooled chill molds for casting slabs, billets, bars and pipes. A. Mohr, 513,930, 10/27/27.

Drive for the piston of a die casting machine. Braunschweiger Hüttenwerk G. m. b. H., 514,202, 3/2/30.

Process for electrolyzing halogen salt melts. I. G. Farbenindustrie Akt.-Ges., 514,125, 4/27/29.

Improvements of alloys of noble metals. Deutsche Gold- u. Silber-Scheideanstalt vorm. Roessler & W. C. Heraeus, 514,126, 4/18/25.

Electrolytic process for cleaning the surfaces of metallic objects. M. Wommer, 514,157, 2/3/27.

Welding process. M. Polanyi, 514,289, 1/18/29.

Electrically-driven roller, particularly for rolling mill roller beds. Siemens-Schuckertwerke Akt.-Ges., 514,646 & 514,647, 5/8/29 & 5/18/29.

Hydraulic extrusion press. Fried. Krupp Grusonwerk Akt.-Ges., 514,735, 7/27/28.

Process for making seamless cylindrical hollow bodies. W. Schroer, 514,584. 4/27/29.

Draw-press. The Toledo Machine & Tool Co., 514,585, 3/24/27.

Process for decomposing chromium ore with gases containing hydrogen chloride. I. G. Farbenindustrie Akt.-Ges., 514,743, 4/17/27.

Process for preventing hypereutectoid carburization in the cementation of steel H. I. Schiffler, 514,479, 3/19/27.

Electric annealing furnace. Akt.-Ges. Brown, Boveri & Cie., 514,353, 4/19/28.

Melting, calcining or heating furnace. Heraeus-Vacuumschmelze Akt.-Ges. & W. Rohn, 514,354, 12/19/25.

Self-baking electrode. Det Norske A/S for Elektrokemisk Industri, 514,575, 5/7/26; Norway 5/15/25.

Wire-feed device for arc welding machines. Allgemeine Elektricitäts Ges., 514,759, 11/24/28; U. S. 11/23/27.

Induction furnace with rammed melting hearth. E. F. Russ, 514,357, 12/12/29.

Portable sand-projecting machine. W. Seidemann, 514,767, 8/20/28.

Double molding machine. Badische Maschinenfabrik & Eisengiesserei, 514,768, 5/9/30.

Device for indicating the amount of metal in a chill mold. H. Kamps & H. Zepernick, 514,358, 4/11/29.

Method of securing the cover plates of chill molds. Aluminium Ltd., 514,359, 12/7/28; U. S. 1/27/28.

Two part mold for die casting. S. Junghans, 514,360, 1/8/29.

Process and device for melting metallic waste. Hirsch, Kupfer & Messingwerke Akt.-Ges., 514,442, 1/20/29.

Working up ores and intermediate products containing zinc, lead and copper. A. F. Meyerhofer, 514,537, 12/24/24.

Refining agent for type-metal alloys and process for preparing the same. E. Hoffmann, 514,726, 1/3/28.

Continuous process for separating and refining metals or metallic compounds with different melting points. Hirsch, Kupfer & Messingwerke Akt.-Ges., 514,612, 8/31/28.

Working up fine ores or metallurgical products, particularly lead-bearing dust, Metallges. Akt.-Ges., 514,679, 4/29/27.

Process for the electrolytic recovery of metals, particularly tungsten. H. Hartmann, 514,365, 9/11/28.

Improving silver-copper and silver-copper-cadmium alloys. Deutsche Gold- u. Silber-Scheideanstalt vorm. Roessler, 514,772, 4/7/26.

Salt bath for annealing metal objects. W. Frey & Co., 514,366, 1/31/30.

Immersion pyrometer for molten metals. R. Hase, 514,682, 5/11/29.

Electrolytic process for the formation of protective layers of lead peroxide. Siemens & Halske Akt.-Ges., 514,621, 10/23/27.

Welding of pipes meeting at an angle. A. Pozdena, 514,490, 3/4/28; Czechoslovakia 3/8/27.

Method of welding tubing tangentially to surfaces to be cooled or heated. R. Samesreuther, 514,550, 8/13/26.

Cutting or welding machine. Akt.-Ges. für Tiefbohrtechnik & Maschinenbau vorm. Trauzl & Co., 514,551, 8/6/29; Austria 7/13/29.

Process for making finely granulated metal from molten metal. Hartstoff-Metall Akt.-Ges., 514,623, 12/6/28.

Method of making tableware with reinforced places. M. Schmitz, 514,553, 4/3/30.

Dry backfire check for welding burners. O. Wolf, 515,009, 8/31/29.

Device for placing on the tips of autogenous cutting and welding burners. H. Jass, 515,194, 12/4/29.

Mandrel arrangement for rolling mills. Mannesmannröhren-Werke, 515,176, 6/15/27.

Extrusion press. Adolf Kreuser G. m. b. H., 514,819, 11/9/29.

Process for drying the blast for shaft furnaces, particularly blast furnaces. G. Malyoth, 515,216, 10/5/26.

Tilting device for drum furnaces, drum forehearths and mixers rotating about their longitudinal axes. Gewerkschaft Eisenhütte Westfalia, 515,041, 1/10/29.

Production of acid- and rust-proof objects. Poldihütte Akt.-Ges., 514,944, 9/2/23.

Process for heat treating the cores of loading coils, especially those made of high permeability materials. International Standard Electric Corp., 514,912, 8/9/27; U. S. 11/15/26.

Furnace for the production of aluminum. P. E. Fröland, 515,229, 3/6/28; Norway 3/12/27.

Method of annealing large metal billets. C. Lorenz Akt.-Ges., 515,013, 7/3/28.

Blast ducts for cupolas. F. Schinke, 515,239, 3/21/29.

Process for casting in liquid-cooled permanent molds. H. A. Schwartz, 514,-875, 3/4/24.

Device for extracting pipes or similar cylindrical objects from molds. Centrifugal Castings Ltd., 515,138, 12/11/28; Great Britain 1/17/28.

Centrifugal casting machine for making hollow bodies in horizontal molds. A. Possenti & C. Scorza, 515,139, 8/14/29; Italy 4/4/29.

Aluminum furnace having a magnetic stirring device. H. Thoma, 514,919, 12/4/28.

Machine for bending tubing. H. Westerbarky, 515,158, 3/25/28.

Cutting and welding burner using liquid fuel. S. Weil & G. Lotzow, 515,537, 5/23/29; France 5/2/29.

Sheet metal folding machine. A. Kramlowski, 515,381, 5/8/29.

Device for feeding tubing to expanding rolls. Mannesmannröhren-Werke, 515,303, 11/27/29.

Crank or eccentric presses, particularly extrusion presses. L. Schuler Akt.-Ges., 515,462, 1/17/29.

Process for making annular depression in metal sheets. Firma Eduard Theisen, 515,445, 12/28/26.

Process for making metallic carbonyls. I. G. Farbenindustrie Akt.-Ges., 515,464, 8/19/28.

Device for pounding material out of rotary furnaces. Gewerkschaft Eisenhütte Westfalia, 515,392, 11/24/29.

Method of improving the operation of shaft furnaces and other melting furnaces. Vulcan-Feuerung Akt.-Ges., 515,315, 9/6/27.

Process for making objects that are composed partly of white gold. Deutsche Gold- u. Silber-Scheideanstalt, vorm. Roessler, 515,579, 10/15/26.

Machine for bending iron bars, etc., E. Kibler, 515,582, 6/13/28.

Cutting or welding apparatus. Akt.-Ges. für Tiefbohrtechnik u. Maschinenbau, 515,354, 8/6/29; Austria 7/13/29.

Italian Patents

Subject of Invention, Patentee, Patent No. and Filing Date.

Process for reducing zinc and other volatile metals from their ores and the like. H. E. Coley, 271,922, 8/18/28, Great Britain 9/14/27.

Improvements to processes for heat treating metals, and apparatus in which use is made of a mass of molten metal. C. F. Hammond & W. Shackelton, 271,504, 7/26/28.

Method and apparatus for the electrolytic deposition of metals. E. Kelsen, 271,622, 7/24/28.

Process for deforming a crystalline metallic body. N. V. Philips' Gloeilampenfabrieken, 271,921, 8/18/28, Netherlands 6/21/28.

Process for reducing sulfidic ores. H. Skappel, 271,881, 8/8/28.

Process for producing a material which is as little as possible subject to cold-shortness, ageing and blue-brittleness. Vereinigte Stahlwerke Akt.-Ges., 271,421, 8/6/28, Germany 8/6/27.

Process for producing a material (iron or steel) having little tendency to cold-shortness and blue-brittleness nor to become brittle when aged naturally or artificially. Same patentee, 271,744, 7/20/28, Germany 7/21/27.

Annealing box. Aciéries Réunies de Burbach-Eieh-Dudeloonge S. A., 271,-288, 7/11/28, Luxembourg 4/27/28.

Improvements to molds for die-casting metal objects, such as pistons. Aluminium, Ltd., 271,785–271,787, 8/6/28.

Casting process. Eisen u. Stahlwerk Walter Peyinghaus, 271,440, 8/6/28.

Process for refining metals, particularly iron and steel. Ges. für Industriegasverwertung m. b. H., 271,884, 8/20/28; Germany 9/28/27.

Improvements in the hardness testing of metals or in testing hardness with simultaneous hardening of the metal. E. G. Herbert, 271,833, 8/27/28; Great Britain 8/29/27.

Die casting process and machine for use with this process. S. Junghans, 271,-755, 7/20/28; Germany 12/20/27.

Process for producing metallic materials having a fibrous structure. Kaiser Wilhelm Institut für Eisenforschung e.V., 271,829, 8/24/28; Germany 9/10/27.

Process for increasing the elastic limit or ductility of structural elements made of strong and forgeable metals. G. Kérekyártó, 271,597, 7/18/29; Hungary 8/11/27.

Process for the bright chromium-plating of iron and aluminum objects. H. Leiser, 271,463, 7/21/28; Germany 7/21/27.

Casting machine. J. Polak, 272,097, 7/4/28.

Coating for arc welding electrodes. La Soudure Electrique Autogéne S.A., 271,759, 7/23/28; France 3/11/28.

New type of cast object and process and apparatus for producing the same. Temple, Inc., 271,446, 7/27/28; U. S. 8/1/27 (Patent No. 1,650,307).

Process for working down ingots and semi-finished non-round objects of steel and the like. H. A. Waldrich G. m. b. H., 271,531, 5/21/28; Czechoslovakia 4/15/22.

New type of bearing lined with antifriction metal and process for making it. Cleveland Graphite Bronze Co., 272,059, 8/16/28.

Method of making electrodes. Det Norske A/S for Elektrokemisk Industri, 271,391, 7/18/28; U. S. 7/19/27.

Apparatus for examining substances by means of X-rays. N. V. Philips' Gloeilampenfabrieken, 271,970, 8/23/28; Netherlands 2/28/28.

Shaft furnace for treating solid substances with gases. A/S Norsk Staal, 271,934, 8/22/28.

Improvements to high-voltage arc furnaces. A/S Norsk Staal, 271,980, 8/22/28.

Electric resistance for carrying heavy currents, particularly for electric furnaces. G. Malaguti, 271,549, 8/6/28.

Improvements to open-hearth furnaces. "Terni" Societá per l'Industria e l'Electricita, 271,270, 4/6/29.

Norwegian Patents

Subject of Invention, Patentee, Patent No. and Filing Date.

Process for rolling thin strip iron and the like. C. Rötzel, 48,667, 5/4/28.

Process for converting liquid slags and the like into a porrous form. Dekt Nors. A/S foElektrokemisk Industrie, 48,692, 2/27/29.

MANUFACTURERS' LITERATURE REVIEWS

In this department we each month list the catalogs and other printed matter issued by manufacturers. Unless otherwise noted, any of the items listed may be secured free upon application to the issuing firm. Manufacturers who have not yet sent in their printed matter are invited to do so.

201 **Stokers.**—The Combustion Engineering Corporation, 200 Madison Avenue, New York, has issued a new catalog describing the Type-E Underfeed Stoker manufactured by them. This stoker is applicable to boilers ranging from 150 hp. up to 600 hp. The catalog includes line drawings showing application of this stoker to various types of boilers.

202 **Flow Meters.**—The Brown Instrument Company of Philadelphia, Pa., is sending out an unusual card model illustrating the principle of their flow meters. This has on the back a table of pipe capacities.

203 **Die Casting Handbook.**—The object of this handbook is to supply general information to engineers who are already familiar with the die casting process. It contains data on the Stewart Die Casting Alloys. Stewart Die Casting Corporation, 4535 Fullerton Avenue, Chicago, Illinois.

204 **Nickel Alloy Steel Products.**—The International Nickel Company, Inc., 67 Wall Street, New York, N. Y., has published a 16-page Buyers Guide to these products, which is a tabulation of sources of supply for the more commonly used forged, rolled, cast or drawn products made from Nickel Steels and Alloys. This edition contains footnotes concerning the size ranges and production limitations of the various concerns listed.

205 **X-Ray Spectrograph.**—Dr. Müller's X-ray spectrograph is capable of being used for any of the principal methods of X-ray spectrography and crystallography in which photographic recording is made use of and in addition can be employed as an optical crystal goniometer. A booklet describing it is sent out by the Adam Hilger, Ltd., 24 Rochester Place, Camden Road, London.

206 **Lead.**—The first issue of this periodical published by the Lead Industries Association, 420 Lexington Avenue, New York, describes a number of interesting uses of lead.

207 **Heat-Treating.**—The Surface Corporation, Toledo, Ohio, is distributing a reprint of an article entitled, 'Continuous Heat-Treating." This is a very complete description of their conveyor type automatically controlled furnace equipment with automatic fuel cut-outs and automatic timing devices.

208 **Gears.**—Book No. 1274 issued by the Link-Belt Company of Philadelphia, Pa., is a 16-page pamphlet descriptive of their recently announced all-metal variable speed transmission.

209 **Foundry Machines.**—The December issue of "Better Methods," published by the Beardsley & Piper Company, Chicago, Illinois, is devoted to a description of their units: sandslingers, sandmuller, sandarators, magnetic separators, and reciprocating riddles.

210 **Annealing Furnaces.**—The Westinghouse Electric & Mfg. Company, East Pittsburgh, Pa., has just released a leaflet describing their rectangular and cylindrical bell type annealing furnaces. The advantages of these furnaces are close temperature control, controlled atmosphere and simplicity of operation.

211 **Sound Ingots.**—The Gathmann Engineering Company, Baltimore, Maryland, have compiled a 88-page book, "Ingot Contour and its Relation to Sound Steel." This is a very thorough discussion of the production of ingots for high quality steel. Price $1.00.

212 **Testing Machines.**—Herman A. Holz, of 167 East 33rd Street, New York, has issued a very interesting pamphlet discussing the Amsler Hydraulic testing machines versus lever types of machines.

213 **Plating Machines.**—Bulletin No. 313 is a very thorough discussion of the Meaker Straight-A-Way and Return Type Machines, indicating the economies effected by the use of this equipment. The Meaker Company, 1615 South 55th Avenue, Chicago, Illinois.

214 **Refractories.**—The E. J. Lavino and Company, Philadelphia, Pa., had a competent engineering firm survey their Plastic K-N and Kromepatch while in actual use. Copies of these surveys, LC-104-CZ, LC-109-AZ and LC-102-HZ, can be obtained upon request.

215 **Automatic Control.**—This booklet describes and illustrates how automatic control renders its aid as though it were humanly directing your process to meet changing operating conditions and requirements freeing the human element from its limitations. Brown Instrument Company, 4482 Wayne Ave., Philadelphia, Pa.

216 **Bearing Tester.**—This is a leaflet describing an acoustimeter for the inspection of ball and roller bearings. The function, operation and advantages of the Burgess Bearing Tester are also given. Burgess-Parr Company, 111 West Monroe St., Chicago, Ill.

217 **Oscillographs.**—Bulletin GEA-954A describes and illustrates the Cathode-Ray Oscillograph. This instrument has its principal use in the recording of extremely fast or transient phenomena. It can be used for the study of the effect of artificial lighting or by a slight modification, of natural lighting. General Electric Co., Schenectady, N. Y.

218 **Industrial Heating.**—A new publication covering Industrial Heating Equipment has recently been issued by the Westinghouse Electric and Manufacturing Company, East Pittsburgh, Pa. Consisting of 100 pages it includes operating data, charts, tables and installation photographs in addition to specifications and illustrations of industrial heating equipment.

219 **Electroplating Aluminum.**—This instructive booklet issued by the Aluminum Company of America, Pittsburgh, Pa., gives in great detail the method of plating aluminum using different deposits. Several plates and tables make the book even more complete.

220 **Steam Generating Equipment.**—A sixteen-page catalog, GC-6, illustrates and briefly describes the fuel burning and steam-generating equipment manufactured by Combustion Engineering Corporation, 200 Madison Ave., New York. A complete list of C-E products is given.

221 **Tachometers.**—Catalog No. 46, issued by the Brown Instrument Company, Philadelphia, Pa., contains 16 pages with illustrations of Brown Indicating and Recording Tachometers in various models, together with the electric generators used in operating them. There are also illustrations and data covering standard applications of this equipment.

222 **Electrical Equipment.**—The General Electric Company, Schenectady, New York, has issued a number of new leaflets to be inserted in their GEA folder. These describe Resistor Arc Welders, Hand Starting Compensators, Fan-cooled Induction Motors, Magnetic Switches and Oil Circuit Breakers.

223 **Special Furnaces.**—A four-page folder sent out by the Surface Combustion Company, 2375 Dorr Street, Toledo, Ohio, describes an SC Car Bottom Annealing Furnace installed in the plant of the Link Belt Company.

224 **Coating Tanks.**—Bulletin No. 200 sent out by H. O. Swoboda, Inc. Pittsburgh, Pa., is a seven-page booklet discussing the "Falcon" electrically heated vertical large coating tanks for asphalts, tars, oils, varnishes and similar substances. Bulletin No. 170 is devoted to electrically heated compound melting tanks and Bulletin No. 190 to continuous electric furnaces for heat treating strip metal and wire.

225 **Brass Rod.**—A small folder published by the Titan Metal Manufacturing Company, Bellefonte, Pa., describes their Nittany Free Turning Brass Rod giving its chemical and physical properties as compared with six samples of other brass rods.

226 **The Laboratory.**—A recent issue of this publication by the Fisher Scientific Company, Pittsburgh, Pa., contains an article on a new atomizing pipette for use in gas analysis and a description of the Plug-Easer, a handy laboratory tool for loosening "frozen" plugs in glass stop-cocks.

227 **Stuart Oils.**—The second edition of this book, compiled by the D. A. Stuart Company, Chicago, Ill., includes much useful data on the kind of oil for use in different operations. The book is fully illustrated with tables and diagrams.

228 **Manganese Steel.**—The November issue of the Amsco Bulletin, issued by the American Manganese Steel Company, Chicago Heights, Ill., contains an interesting article on manganese steel sheaves as a means of saving rope as well as illustrations of manganese steel stone quarrying machine parts.

229 **Nirosta KA2 and KA4.**—The Associated Alloy Steel Company, Cleveland, Ohio, has printed three more pamphlets in their Technical Bulletin Series. These are: Resistance of Nirosta KA2 and KA4 against Chemical Attack, The Physical Properties of Nirosta KA2 and Fabrication of Nirosta.

230 **Westinghouse Catalog.**—The Westinghouse General Catalog, 1931–32, comprised of 1352 pages, presents descriptions and illustrations of apparatus manufactured and sold by the Westinghouse Electric and Manufacturing Company, East Pittsburgh, Pa.

231 **Pyrometers.**—Potentiometer pyrometers made by the Leeds & Northrup Company, Philadelphia, Pa., are accurate and well capable of withstanding rough service. They are described in a leaflet issued by the company.

232 **Refractories.**—A recent issue of *Grits & Grinds*, published by the Norton Company, Worcester, Mass., reprints an interesting article from Industrial Gas entitled "Alundum Refractories in Some Modern Gas Furnaces." A 16-page booklet issued by the company tells the whole story of the new Norton markings and "What is Controlled Structure?"

233 **Nickel Cast Iron.**—The December issue of this periodical published by the International Nickel Company, 67 Wall Street, New York, contains a brief history of cast iron, one of the series of Intimate Chats on Metallography and several important applications of nickel cast iron.

234 **Power Notes.**—The September-October number of this publication of the Diamond Power Specialty Corporation, Detroit, Mich., presents an interesting article on "Lowering Steam Consumption of Heating Systems," as well as one entitled "Superheated Steam Has Advantages in Drying Processes" and "Better Combustion with Clean Coal."

235 **Inspection.**—An attractive and well-planned booklet issued by the Pittsburgh Testing Laboratory, Pittsburgh, Pa., brings out the value of careful inspection of materials used in all construction.

236 **Small Power Motors.**—Circular 1883, a current publication of the Westinghouse Electric & Manufacturing Company, East Pittsburgh, Pa., contains many illustrations showing construction details of their small power motors, their external appearance and some of their applications. Another publication of the same company is entitled "Cars and Car Equipment."

237 **Steel.**—A leaflet sent out by the Edgar Allen Steel Co., Inc., 741 Washington Street, New York, illustrates their "iron fibred steel" and lists a number of their other products.

238 **Welding.**—Several valuable articles on welding are found in the October issue of "The Welder." These are: Welding for the Chemical Industry, Electric Welding of Mild Steel by the Metal Arc Process and The Acetylene Welding of Copper. Published by Murex Welding Processes, Ltd., Ferry Lane Works, Forrest Road, London, England.

METALS & ALLOYS

Devoted to Engineering Metallurgy

PUBLISHED MONTHLY BY THE CHEMICAL CATALOG COMPANY, INC.

419 Fourth Ave., New York

Editorial and Advertising Offices: 3619 Forbes Street, Pittsburgh, Pa.

Annual Subscriptions: U. S., Possessions, Mexico and Cuba, $3.00; Canada, $3.50; Other Countries, $4.00; Single copies, 40¢.
Copyright, 1931, by The Chemical Catalog Company, Inc. All rights reserved. Entered as second-class matter July 23, 1929, at post office at Easton, Pa., under the act of March 3, 1879.

CURRENT METALLURGICAL LITERATURE ABSTRACTS

These abstracts are not critical, but merely review developments. The classification number at the end of each abstract will be of assistance in mounting them on filing cards.

Negative print photostats of the original articles abstracted below can be obtained at 35 cents per page, plus 10 cents for mailing first class. The remittance should accompany the order.

CONTENTS—MARCH 1931

	Page		Page
Properties of Metals	62	Joining of Metals & Alloys	70
Properties of Non-Ferrous Alloys	62	Working of Metals & Alloys	71
Properties of Ferrous Alloys	63	Defects	73
Corrosion, Erosion, Oxidation, Passivity & Protection of Metals & Alloys	64	Chemical Analysis	73
Structure of Metals & Alloys	65	Economic	74
Physical, Mechanical & Magnetic Testing	66	Foundry Practice & Appliances	74
Electro-Chemistry	67	Furnaces & Fuels	75
Metallic Coatings Other than Electroplating	68	Refractories & Furnace Materials	75
Heat Treatment	69	Gases in Metals	76
		Inspection	76

GENERAL (0)

Value of Research in Non-Ferrous Metals. H. W. GILLETT. *Metal Industry* (London), Vol. 37, Aug. 8, 1930, pages 121–123.

Condensed from a paper read before the American Zinc Institute at St. Louis. Cites several recent expansions in research laboratory construction, due to the increased importance of scientific investigation. Research is insurance for tomorrow's profits. The Al business is built on finding, by research, the real facts as to their materials. The research department is the mainspring of the Al industry. Investigations on Mg have been in progress for several years, but progress is very slow. The International Nickel Co. ascribes its success in the last few years to the activities of its research department. Work of the Copper and Brass Association mentioned. Takes up the various uses of Zn and Zn alloys, and suggests further scientific research. VSP(0)

Tenth Report of the German Atomic Weight Commission. (X. Bericht der deutschen Atomgewichts-Kommission.) M. BODENSTEIN, O. HAHN, O. HÖNIGSCHMID & R. J. MEYER. *Berichte der deutschen Chemischen Gesellschaft*, Vol. 63, Jan. 8, 1930, pages 1–24.

Contains 70 references and gives a summary of investigations on atomic weights since Dec. 1928 on H, A, C, S, P, Cu, Hg, B, Pb, from Act., N, As, Sb, Cl, Re and Ni. Isotropes are discussed and revised tables of atomic weights and isotropes are given. CEM(0)

A Project of International Collaboration in Metallurgy. (Un projet de collaboration internationale en metallographie.) ALBERT PORTEVIN. *Revue de Metallurgie*, Vol. 27, Aug. 1930, pages 436–438.

During last autumn meeting of the Institute of Metals in Düsseldorf attention was called to the importance of bringing workers in different countries in contact with the latest developments of metallurgy. The question was resumed at the Spring Meeting of the Institute in London and the committee appointed at the former assemblage was able to formulate the optimum method for achieving it. Every country in which metallurgical work is being done shall appoint one or several persons of eminence in metallurgical work which once or twice a year will review the work of their country and communicate it to the international commission which will forward it to the societies of different countries for publication in their journals after translation. No new society or organization is proposed. The existing national societies are invited to nominate these members and communicate their names to provisional Commission of International Metallurgical Collaboration, Institute of Metals, 36 Victoria Street, London, S. W., England. The first meeting of the new commission is proposed for October at Düsseldorf. JDG(0)

Quality Steel Bar of Today Is Result of Long Period of Evolution. *Iron Age*, Vol. 126, Aug. 7, 1930, pages 325–348.

Traces developments which have kept steel makers busy to produce steel bars of dependable quality, to meet all requirements. Bessemer process wrought wonders in steel industry and greatly amplified uses of steel bars. Gives early classification of Bessemer steel for various uses. Railroads were the first to issue specifications and they varied as the engineers of each road differed in training and experience. Several grades of bars were determined by the amount of C they contained. Four factors affecting quality of steel are: method of manufacture, chemical composition, deformation process and heat treatment. Sound forging steel is made by open-hearth process with a scrap and pig Fe charge. Rolling processes have been improved in recent years. Exacting requirements of present day users leave much to be accomplished in future. VSP(0)

Some Trends in Science as Indicated by Accomplishments in 1929. H. E. HOWE. *Engineers & Engineering*, Vol. 47, Mar. 1930, pages 54–58.

A brief review of a series of industrial developments during 1929, among them the perfection of the high-Cr high-Ni alloy "Nirosta." (0)

The Increasingly Important Role of Chemistry in Steel Making. C. H. HERTY, JR. (U. S. Bureau of Mines). *Iron Age*, Vol. 126, Aug. 14, 1930, page 431.

From a report to the iron and steel section of the National Research Council's Science Advisory Committee. Major role of chemistry in steel making has been to formulate methods for determination of various substances in steel, once the effect of these substances has been determined by metallurgists. Scientific investigations on steel making may be divided into definite periods so far as type of work is concerned. Considers work that has been done from 1860 to 1930. VSP(0)

Steel Metallurgy in 1929. C. H. HERTY, JR. *Blast Furnace & Steel Plant*, Vol. 18, Jan. 1930, pages 83–84; *Heat Treating & Forging*, Vol. 16, Feb. 1930, pages 181–182.

Among the important developments are the Aston process for the production of wrought iron and the increase in alloy steel applications. Much interest has been shown in nitrided steels. In the open-hearth furnace, greatest advances have been made in combustion control and in a better appreciation of the necessity of slag control. MS(0)

Interesting Uses of Barium and Beryllium. H. W. GILLETT. *Metals & Alloys*, Vol. 1, Nov. 1930, page 811.

An editorial pointing out the economies available to industry through the application of high precision scientific work to industry. ESC(0)

Le Chatelier's Principle. H. W. GILLETT. *Metals & Alloys*, Vol. 1, Oct. 1930, page 754.

An editorial. An argument in favor of fewer rules, regulations and restraints for technical metallurgists is presented as an encouragement for more genuine interest. ESC(0)

Eighteen and Eight. H. W. GILLETT. *Metals & Alloys*, Vol. 1, Oct. 1930, pages 753–754.

An editorial. A survey of the austenitic metallurgy which is commercially culminated in the 18–8 chrome nickel steel is offered. The numerous desirable properties of this alloy are extolled and the furtherance of austenitic alloy development in the direction of the 18–8 chrome-manganese is indicated. ESC(0)

Quality Factors. H. W. GILLETT. *Metals & Alloys*, Vol. 1, Nov. 1930, page 811.

An editorial pointing out the inaccuracy of any method of designating the quality of steel by numbers because of the multiplicity of variables involved. ESC(0)

Alloy Steels of Yesterday, Today and Tomorrow. EDWIN F. CONE. *Iron Age*, Vol. 126, Nov. 20, 1930, pages 1485–1487.

Alloy steels had their origin within the last 30 or more years. Cr and Ni play the major role in present-day alloy steels. Cr has been used as early as 1870. Gives an account of Julius Bauer's patented chromium steel in 1871. Origin of high-speed steel is credited to the work of Taylor and White. Birth of American alloy steel industry of today should be credited to the work of Rossi, de Chalms, Becket and others. Flannery, J. Kent Smith and others introduced Va and Mo. Electric melting in this country is credited to Moore, Snyder and others, although Stassano of Italy, Rodenhauser of Germany and Heroult of France are pioneers in electric melting development. Considers what scientific research has done in the development of ferrous and non-ferrous alloys. VSP(0)

A List of Alloys. WILLIAM CAMPBELL. *Proceedings American Society for Testing Materials*, Vol. 30, Pt. 1, 1930, pages 336–397.

Campbell's list of non-ferrous alloys, which has been so useful for reference, has been brought up to date, and greatly enlarged. There are about 8000 compositions listed. The physical properties of the standard and widely used alloys are given from American Society for Testing Materials specifications and from other sources. The utility of the list has thereby been vastly enhanced. It can be purchased separately from the bound volume of Proceedings. HWG(0)

PROPERTIES OF METALS (1)

Tantalum. FREDERICK GROVE-PALMER. *Sheet Metal Industries*, Vol. 4, Dec. 1930, pages 669–70.

The properties of the metal are set forth and possibilities of uses suggested, e. g., "diamond" drills, because of the hardness developed by the addition of a small percentage of carbon. AWM(1)

Vanadium and Its Applications. (Le vanadium et ses applications.) R. SEVON. *Journal du Four Electrique*, Vol. 39, Sept. 1930, pages 329–332.

Brief information regarding the ores, properties and application of V and its compounds. Taken largely from the literature of Vanadium Corporation. Description of their Bridgeville plant and laboratories is given. JDG(1)

The Metallic Character of Clean Platinum Contacts. (Eine Kontrolle des metallischen Charakters von Platinkontakten.) RAGNAR HOLM & RUDOLF STOERMER. *Wissenschaftliche Veröffentlichungen aus dem Siemens-Konzern*, Vol. 9, No. 2, 1930, pages 323–330.

Experiments have been made to determine how platinum contacts behave under very high pressures. It can be concluded that clean contacts have a pure metallic conductivity at high pressures (to 1% exactly), and that Ohm's law holds good for current densities up to 4.3×10^6 amperes per cm.^{2} HA(1)

Measurement of the Thermal Conductivity of a Platinum Sample in the Temperature Range between 19 and 1020° C. (Messung der Wärmeleitfähigkeit einer Platinprobe im Temperaturgebiet 19–1020° C.) RAGNAR HOLM & RUDOLF STOERMER. *Wissenschaftliche Veröffentlichungen aus dem Siemens-Konzern*, Vol. 9, No. 2, 1930, pages 312–322.

The specific resistance and the thermal conductivity of a 99.95% platinum sample was measured according to the method of Kohlrausch, Diesselhorst and Meissner and can be expressed, respectively, by the following equation:

$$c = 1.048 \times 10^{-5}[1 + 3.695 \times 10^{-3} (\vartheta - 15) - 5.98 \times 10^{-7} (\vartheta - 15)^2 + 5.25 \times 10^{-11} (\vartheta - 15)^3]$$

$$k = 0.699 [1 + 2.83 \times 10^{-4} (\vartheta - 19.5°)]$$

A table is given from which the errors of measurement can be taken. Ha(1)

A Method for the Determination of Thermal Conductivity of Metals, Especially at Elevated Temperatures. (Eine Methode zur Bestimmung der Wärmeleitfähigkeit von Metallen, besonders bei hohen Temperaturen.) RAGNAR HOLM. *Wissenschaftliche Veröffentlichungen aus dem Siemens-Konzern*, Vol. 9, No. 2, 1930, pages 300–311.

In order to be able to use the method of Kohlrausch, Diesselhorst, and Meissner, also for very elevated temperatures the metal rod which is used in this test was modified so that the losses due to radiation could be neglected; the author therefore gave the sample a shape of 2 thick short cylinders which are connected by a very short, thin collar. The theoretical derivation for the method and an example showing the application for the computing of time for reaching final temperature is given, also 11 references. Ha(1)

The Electrode Potential of Indium Against Indium Chloride Solutions. SHIN'ICHIRO HAKOMORI. *Journal American Chemical Society*, Vol. 52, June 1930, pages 2372–2376.

The molal electrode potential at 25° C. of In(s), In^{+++} is given as + 0.336 volt referred to the molal hydrogen electrode. MEH(1)

The Temperature Dependence of Crystal Elasticity. II. (Ueber die Temperaturabhängigkeit der Kristallplastizität. II.) W. FAHRENHORST & E. SCHMID. *Zeitschrift für Physik*, Vol. 64, Sept. 22, 1930, pages 845–855.

It was previously found that the slip energy is independent of temperature and stretching velocity in the case of Cd crystals. The same result was obtained with single crystals of Zn (slip energy 0.97 cal./g.). Diagrams relating slip and slip tension are given for the temperature from —253° to 250° C. At higher temperature recrystallization disturbs these regularities. Below —83° rupture occurs by splitting along a basal face. (1)

Fundamentals of the Plasticity of Crystals and Investigation of Its Theoretical Interpretation. (Grundtatsachen der Kristallplastizität und Versuche zu ihrer theoretischen Deutung.) W. BOAS & E. SCHMID. *Mitteilungen der deutschen Materialprüfungsanstalten*, Sonderheft 13, 1930, pages 98–102.

General review of the situation as to the critical gliding stress and elastic limit of single crystals, chiefly based on experimental work of Polanyi and Schmid. The elastic limit found experimentally is only $^1/_{1000}$ to $^1/_{10000}$ of that calculated by present theory. A satisfactory theory must explain this, the law of critical gliding stress, why the gliding stress is so little affected by temperature, and why hardening occurs on the occurrence of slip. The theories of Voigt, Becker, Smeckal and Polyani are briefly mentioned. While there is to-day no general theory of crystal plasticity, this mysterious subject is so important to theoretical physics that it is to be hoped it will presently be cleared up. HWG(1)

Thirty-Sixth Annual Report of the Committee on Atomic Weights. Determinations Published during 1929. GREGORY PAUL BAXTER. *Journal American Chemical Society*, Vol. 52, March 1930, pages 857–862.

The only change in the atomic weight table given in this article is the lowering of As from 74.96 to 74.93. MEH(1)

The Selection of Tin for Fabrication. C. L. MANTELL. *Metals & Alloys*, Vol. 1, Aug. 1930, pages 645–648.

Sb, As, Pb, Bi, Cu and Fe are the common impurities in commercial ingot tin which render it harder and grayer. Uniformity of properties desired is obtained by uniformity of metal. It is marketed in 2 classes determined by Sn content. These are the class A Standard Sn and the class B 99% Sn of a variety of brands which indicate the origin of the ore or the smelter and consequently the quality of merchandise. Gueterbock and Nicklin observed a lowering of the freezing point upon addition of traces of Pb, Cu, Zn, As and Fe, and a raising of the freezing point upon addition of Sb and S. Small additions of Cu and Pb softened the metal and greater quantities increased the hardness. Bi had the reverse effect. Sb, As, S, Fe and Zn increased the hardness. Data regarding hardness numbers, compression yield points, tensile tests, reduction of area are tabulated. The bend test is the most reliable guide, observations are included concerning the effect of various impurities. Comment is made upon bath losses through dross and the effect thereupon due to impurities. Coe observed that cylinders of Sn, Pb, and their alloys tested under compression of regularly increasing loads did not yield smooth curves when the changes in height and diameter were plotted in the form of load strain diagrams during the semi-plastic and plastic ranges but yielded discontinuities. This is termed critical plasticity and is characteristic of all metals. The observations on Sn are tabulated. Sn is white with a slightly bluish tinge. Thin films of the metal transmit brown light. The reflected light is whiter than Ag or Zn. The metal is decidedly crystalline. The crystals may be broken by cold working but are readily reformed by heating. ESC(1)

Heat Treatment, Ball-Hardness, and Allotropy of Lead. F. HARGREAVES. *Engineering*, Vol. 130, Sept. 26, 1930, page 389.

Abstract of paper read before the Institute of Metals, Southampton, Sept. 11, 1930. See *Metals & Alloys*, Vol. 1, Dec. 1930, page 897. LFM(1)

Gallium, Germanium, Indium, and Scandium. ALICE V. PETAR. *Information Circular* 6401, *United States Bureau of Mines*, Nov. 1930, 17 pages.

A description of these 4 metals is given under the following headings: properties, history, occurrence, ores, production, list of dealers, markets and prices, metallurgy. Over 100 footnote and bibliographic references are given. AHE(1)

PROPERTIES OF NON-FERROUS ALLOYS (2)

Physical Properties of Electrically Conducting Wires at Low Temperatures. (Die Festigkeitseigenschaften von elektrischen Leitungsdrähten bei tiefen Temperaturen.) F. PESTER. *Zeitschrift für Metallkunde*, Vol. 22, Aug. 1930, pages 261–263.

Pulling and bending tests with wires of copper, bronze, pure aluminum, and Aldrey after varying storage times over the temperature range of —60° to +20° C. Tensile strength, elongation and bending value increase in general with decreasing temperatures down to —60° C. Changes in physical properties due to cold work during drawing are discussed. EF(2)

The Influence of Reheating upon the Resistivity and Resistance to Shearing of Alloys of Aluminum and Silicon. (Influence du revenu sur la résistivité et la résistance au cesaillement des alliages aluminium-silicium trempes.) LEON GUILLET & MARCEL BALLAY. *Comptes Rendus*, Vol. 190, June 23, 1930, pages 1473–1475.

The alloys used contained 0.4% of Fe and the Si varied between 0.14 and 2.56%. The resistivity of a wire previously heated for 30 min. at 500° and 600° C., reheated for varying times and temperatures, varied rather uniformly from 2.71 to 3.13 microhms/cm.^{3} 5 tables are given. The change in the resistance to shearing with different degrees of reheating, 150° and 200° C., when previously heated at 600° then at 500° is noted. (2)

Silver Solders. R. H. LEACH. *Proceedings American Society for Testing Materials*, Vol. 30, Pt. 2, 1930, pages 493–511; *Metal Industry* (London), Vol. 37, Oct. 10, 1930, pages 337–340.

Recovering Lead in Rubber Factory. F. L. HAUSHALTER (B. F. Goodrich Co.). *Chemical & Metallurgical Engineering*, Vol. 37, Feb. 1930, page 92.

The tensile strength of Pb, which is ordinarily 1900 lbs./in.^{2}, increased to about 2400 lbs./in.^{2} after it was melted and extruded onto wire and hose and removed therefrom. The percentage of elongation, however, decreased from about 50 to about 25. The tensile strength fell considerably below the original value at the temperature of vulcanization (280° F.). The tensile strength-temperature curve approximated a straight line. At 280° F., Pb began to yield at a stress of about 600 lbs./in.^{2} Dross Pb showed a straight line to the breaking point, less than 700 lbs./in.^{2} Refined dross yielded at 900 lbs./in.^{2}, while pure Pb began to yield at 700 lbs./in.^{2} The following table gives the tensile strengths in lbs./in.^{2} at the temperatures indicated:

	80° F.	280° F.
Pure lead, pig	1880	1239
Lead tube, before cure	1930	1345
Lead tube, after cure	2390	1385
Refined dross	1810	1118
Dross	400	650

Bearing Metals and Solders. J. BRADLEY. *Electrician*, Vol. 105, Nov. 28, 1930, pages 666–670.

The subject of bearing metals cannot be considered separately from that of lubrication. As the speed rises the friction of a journal decreases rapidly to a point depending on the pressure between the surfaces, and the viscosity of the oil, after which it increases slowly. There are periods, when starting from rest or stopping, in which the oil film does not exist making the metal of which the faces are composed important. A complete film of the lubricant is rarely maintained over a long period. A bearing metal should have as low a coefficient of friction as possible, regardless of the lubricant employed. The properties of efficient bearing metals, the alloys employed, and hard and soft solders are discussed. There is a wide gap between hard solders, requiring a red heat (700° C.) for fusion, and the soft solders of which there are none in general use now, other than the ordinary tin-lead solder with a melting point about 200° C. In addition, there is a similar gap in suitable fluxes, without which, of course, the solders are useless. Several photomicrographs and a melting point curve for Pb-Sn alloys are shown. WHB(2)

The Future of Silver and Its Alloys. W. GUERTLER. *Metal Industry* (London), Vol. 37, July 11, 1930, page 33.

Ag is not used pure, but usually contains alloying metals. German standard Ag contains not more than 20% of other metals, while American standard is $7^1/_2$%. Cu is the most common addition. The Cu alloys are known as "New Ag." Besides Cu they contain Ni, Fe, Zn, Cd, Sn, Al or Si. These new Ag alloys are often superior to Ag alloys in as much as they do not blacken. Another group of alloys is with Fe, at present superior to Ag alloy and known as "V_2A" steel. Ag may be used not as a principal constituent but as an addition to other metals. VSP(2)

P. M. G. Metal for Replacing the Bronzes. M. A. HUNTER. *Heat Treating & Forging*, Vol. 16, March 1930, pages 344–345.

Vickers-Armstrong, Ltd., has developed a Cu alloy substitute for Admiralty gun-metal, in which the 10% Sn of the gun-metal is replaced by 10% of a special hardener. The percentage of hardener may be varied. Alloy as cast contains 2% Fe and 3.4% Si with 2% Zn. Alloy is easily melted, and has a short freezing range of 50° C. It appears to be resistant to oxidation. Sand-cast alloy has an average yield-point of 25,000 lbs./in.^{2}, ultimate stress of 48,000 lbs./in.^{2} and elongation of 11.5% in 2 in. Metal can be readily forged hot. A bar forged at a red heat from a 3 in. round billet to a 1 in. square section had an average yield-point of 50,000 lbs./in.^{2}, ultimate stress of 77,000 lbs./in.^{2}, and elongation of 38% in 2 in. End forged at a black heat to 0.88 in. section had a yield-point of 82,650 lbs./in.^{2}, ultimate stress of 94,000 lbs./in.^{2} and elongation of 17% in 2 in. Brinell hardness of the sand-cast alloy was 104–121, forged, 126–143, and cold-finished, 149–153. Density is 8.45. MS(2)

PROPERTIES OF FERROUS ALLOYS (3)

Low-Expansion Nickel Steel. THOMAS F. RUSSELL. *Engineering*, Vol. 128, Sept. 27, 1929, pages 400–402.

Gives some results of tests carried out on Nilex, a steel containing 36% Ni. It is the Fe-Ni alloy having the lowest coefficient of expansion of all similar alloys under the same conditions of treatment. It was developed for use as clock pendulums, standard tapes for geodetic surveys, standards of length, and for scientific instruments where permanency of dimensions is important. Reviews theories of Guillaume and of Honda on magnetic induction and expansion of Fe-Ni alloys. Tests were carried out by the English Steel Corporation in an attempt to correlate coefficient of expansion, Brinell hardness, and magnetic induction. Includes tables and curves showing results of tests. LFM(3)

Nickel-Iron Alloys. H. J. GARNETT. *Electrician*, Vol. 104, Apr. 4, 1930, page 438.

The qualities of Mumetal are compared with those of Permalloy C particularly in relation to magnetic permeability, lessened susceptibility to impairment of magnetic properties by mechanical strain, and simplification of heat-treatment. WHB(3)

Chromium-Manganese Steels. F. M. BECKET. *Iron & Coal Trades Review*, Vol. 120, June 20, 1930, page 992.

Abstract of a paper, of the same title, presented at the recent meeting of the American Iron & Steel Institute in New York. See *Metals & Alloys*, Vol. 1, Dec. 1930, page 900. RHP(3)

Nickel-Chromium Steels More Widely Used. E. C. KREUTZBERG. *Iron Trade Review*, Vol. 86, April 17, 1930, pages 45–49; April 24, 1930, pages 53–56.

Presents information on the composition, physical properties, heat and corrosion resistance, applications, processing and fabricating methods of Nirosta KA2 and its modifications. It is claimed that much of this is published for the first time. Average composition is: C, under 0.16%; Mn, under 0.50%; Si, over 0.50%; Cr, 17–20%; Ni, 7–10%; P and S, max. 0.025% each. A product with 3% Mo has been developed for the paper industry. On heating to 2100° F. and quenching in water, the KA2 alloy has a tensile strength of 85,000–95,000 lbs./in.^{2}; yield point 30,000–40,000 lbs./in.^{2}, elongation in 2 in., 55–60%; reduction in area, 70–75%; Brinell hardness, 135–145; Izod impact, 115–120 ft.-lbs.; Charpy impact, 100–110 ft.-lbs.; sp. gr., 7.86; heat conductivity, 0.052 g. cal./cc./sec./1° C.; sp. heat, 0.118; m. p., 2550° F.; sp. resistance, 73 microms at 68° F.; coefficient of linear expansion, 0.000020/1° C. from 0–1000° C.; modulus of elasticity, 27,000,000–30,000,000 lbs./in.^{2} It is resistant to attack by most commercial chemicals, air, gases, and water. The halogens and their acids dissolve the metal. To secure best results, it must be used in heat treated condition. Treatment consists in heating the alloy quickly to 2050°–2150° F., and cooling rapidly. It can then be worked, welded, machined, and formed. Cold-working hardens it. Gives details of the procedure to follow in forging, expanding, rolling, belling, flanging, bending, pickling, riveting, welding, soldering, brazing, shearing, punching, drilling, sawing, machining, threading, forming, drawing, spinning, grinding, and polishing. Tabulates the licenses of the Krupp Nirosta Co. MS(3)

Some **Effects of Nickel Content in Austenitic Iron-Chromium-Nickel Alloys.** NORMAN B. PILLING. *Proceedings American Society for Testing Materials*, Vol. 30, Pt. 2, 1930, pages 278–290.

Includes discussion. See *Metals & Alloys*, Vol. 1, Dec. 1930, page 900. (3)

Comparative Tests on Cast Iron (Essais comparatifs des Fontes, en Tchécoslovaquie). F. PISEK. (Ecole Polytechnique, Brno, Czechoslovakia.) *First Communications of the New International Association for the Testing of Materials.* Group A. Zurich, 1930, pages 25–34.

Double shear tests on 15 mm. diameter bars, and to a lesser degree, Fremont shear tests (5.64 mm. diameter) show fair concordance with tensile tests. This conclusion is based on tests of 22 varieties of cast iron. Only the author's conclusions, without details of tests on different irons, are given. (3)

Cobalt Magnet Steels. H. E. KERSHAW. *Edgar Allen News*, Vol. 9, Sept. 1930, pages 701–705.

There are 2 classes of cobalt magnet steels: the low and medium cobalt chrome steels and the high cobalt steels. The cobalt chrome steels are subdivided: one containing 9% and the other 16% Co, but both containing 9–10% Cr, 1.5 Mo and 1.0–1.15% C; these are air-hardening and the best results follow a triple heat treatment. The high cobalt steel usually has 36% Co, with about 6% Cr, 4–6% W, and 0.9% C; these are oil-hardening; only a single treatment is necessary, but accurate temperature control is essential. This alloy has better magnetic properties than any other known at present; B-H max. values of 900,000–1,000,000 are regularly obtained. The high frequency electric crucible furnace is very efficient for the manufacture of cobalt magnet steels; can also be used for cast magnets. With Co-Cr steels better magnetic results are obtained from forged than from cast magnets; the higher the Co content, the greater the discrepancy between the magnetic results. With the 36% Co alloy, cast magnets can be produced having as good, sometimes better, magnetic properties than forged. Some special magnets are described. W(3)

Wrought Iron. H. W. GILLETT. *Metals & Alloys*, Vol. 2, Jan. 1931, pages 25–30.

A correlated abstract. Considerable propaganda is obtainable regarding the corrosion resistant properties of wrought iron due to the presence of slag filaments or high purity of the metallic part of the aggregate. The former argument is considered highly questionable from a technical point of view. Ease of fabrication and the purely physical, rather than the chemical properties are of importance in many applications. It is readily welded, has good threading properties, and readily takes coatings such as galvanizing. Statements have also been made regarding the resistance of wrought iron to fatigue under vibration, to abrasion, as well as its ability to retain its strength at high temperatures. Moore has observed the endurance limits for the rotating beam and axial loading tests—plots are included—which indicate its superiority to *mild* steels. Sisco, Haigh, Moore and Kommer, Wright and Hinde, Howe, Rawdon and Epstein, Souther, Stanton and Barstow, Gough and Murphy and others are quoted as observing lower strength values for wrought iron. Repeated stress laboratory tests have not been borne out in practice as indicated by the use of alloy steel for car axles. Wrought iron has also been found highly satisfactory for car and locomotive piping. Various observations, notably Rawdon and Epstein and MacIntosh and Cockrell show that increase in phosphorus increases the endurance limit. Bernhard has conducted an interesting study of the "recovery" due to rest periods. Trinham, Haigh, and Tudsberry and Gibbs have made observations regarding "recoveries." Need for greater clarity regarding the ability of wrought iron to absorb energy and further data concerning the relation between rest periods and fatigue failure is pointed out. Izod values by Rawdon and Epstein, and Petrenko point to the utility of wrought iron as due to ability to resist impact rather than repeated stress. A balance should be struck between endurance limit and impact strength if we correctly appraise the service value of a material. It is notable that the makers of a material (wrought iron) advertised and advocated for both corrosion-resistance and fatigue-resistance have never published a single test on corrosion-fatigue. ESC(3)

Study of the Pearlitic Manganese Steels. JOHN H. HRUSKA. *Heat Treating & Forging*, Vol. 16, April 1930, pages 455–459; May 1930, pages 598–602; *Blast Furnace & Steel Plant*, Vol. 18, May 1930, pages 802–806; Sept. 1930, pages 1463–1467.

Pearlitic Mn steels are of 3 types, viz., those containing 0.90–1.30%, 1.30–1.60% and 1.60–1.90% Mn. For carburizing steels, C content is 0.15–0.20%, while it is much higher for straight heat treating. Content of P is below 0.035%, and S is 0.100–0.125%. Examination for non-metallic inclusions, surface defects, seams, etc., is best conducted on annealed or normalized stock. Testing for quality in carburizing is based upon the McQuaid-Ehn test. The best index is obtained by counting the number of pearlite crystallites, completely surrounded by fine "veins" of cementite. Most desirable values range from 12×10^4 to 20×10^4. For specific purposes, concentration of C in the surface layers is considered essential. This concentration is nearly always above the eutectoid composition, providing the enriched case is more than 0.031 in. thick. Pearlitic Mn steels are mostly cleaner than other commercial grades of machine steels. Presents tables giving a comparision of the physical properties of pearlitic Mn steels with other alloy steels, and showing the effect of various heat treatments on the physical properties of the Mn steels. Following results serve as illustrations of the variation in properties with heat treatment. Steel in table contained 0.41% C and 1.69% Mn.

Treatment	Drawn at ° F.	Tensile Strength lbs./in.^{2}	Elastic Limit lbs./in.^{2}	Elongation % (2 in.)	Reduction of area %
As rolled		122,450	60,380	21.8	39.0
Quenched in	600	208,300	171,150	10.2	30.8
H_2O from	800	181,900	153,080	13.2	41.4
1475° and	1000	146,580	137,550	18.0	51.9
drawn	1200	114,130	88,850	21.3	57.3
Quenched in	600	167,900	139,000	9.4	36.3
oil from	800	149,180	111,280	13.6	40.0
1500° and	1000	127,330	90,460	20.4	51.3
drawn	1200	106,650	80,430	22.0	62.1

A steel containing 0.21% C and 1.69% Mn had a single impact value of 8.6 ft.-lbs. after quenching from 1650° F. in H_2O and drawing at 600° F. in salt for 2½ hrs. When the drawing temperature was increased to 1000° F., the impact value was 58.9 ft.-lbs. Shaft containing 0.34% C and 1.74% Mn, quenched in H_2O at 1450° F. and drawn at 800° F. had the following hardness numbers: Brinell, 396; Rockwell, C-42.3; Scleroscope, 58.8. When drawn at 1200° F. these were respectively, 26.9, C-28.8, 42.5. Mn improves the tensile properties of steel at higher temperatures. Steel containing 0.18% C and 1.44% Mn had a tensile strength of about 97,000 lbs./in.^{2} at 500° F. and 40,000 lbs./in.^{2} at 1100° F. Tests indicated that for grades containing 0.16–0.21% C, each 0.1% Mn above the amount ordinarily present in structural grades of steel corresponds to increases of 4.3–7.8% in tensile strength at temperatures around 500° F.; whereas at 1000° F., this improvement amounts to 4.8–10.6%. Pearlitic Mn steels are manufactured according to alloy steel practice in the basic open-hearth or electric furnace. Presents typical logs of heats. These steels have advantages in carburizing such as generally lower carburizing temperatures (1600°–1650° F.), 10–35% decrease in carburizing time, and decreased danger of deformation. In straight heat-treating, best results are obtained with grades containing not more than 0.55% C. Commercial grades are preferably quenched in H_2O instead of in oil. Tabulates possible ranges of quenching and drawing temperatures for various grades. These steels are being used in many industries, particularly those relating to transportation. Tabulates many of the applications. In mechanical operations their use results in an increase of 20–90% in feeds and speed. The life of tools is prolonged 35–400%. MS(3)

Gray Iron Possesses Valuable Engineering Properties. *Foundry*, Vol. 58, June 1, 1930, pages 152–154.

In high P gray Fe, physical properties depend on iron phosphide component. In low P the elasticity is dependent on properties and distribution of pearlite, ferrite and graphite. Modulus of elasticity for pure Fe and steels is close to 30,000,000 lbs./in.^{2} Tensile modulus of elasticity for malleable cast Fe is 25,000,000 lbs. Effect of overstrain in steel furnishes a comparison to the effect of primary strain in gray Fe. In higher C commercial Fe much of graphite occurs in whorls. Fracture proceeds through the graphite flakes. Localized stress intensities are higher than average stress intensities. VSP(3)

Production and Properties of Stainless Steels. (Die rostfreien Stähle, ihre Erzeugung und ihre Eigenschaften.) E. HOUDREMONT. *Stahl und Eisen*, Vol. 50, Oct. 30, 1930, pages 1517–1528.

The author classifies the stainless steels in 3 or 4 groups—martensitic, ferritic (semi-ferritic) and austenitic steels—and gives the production methods, the properties and the application of these various groups of steels. All stainless steels are mostly made in electric furnaces, in part in the open hearth furnace. The proper choice of the raw materials is of extreme importance. The various methods of making stainless steels in the open-hearth furnace are described in detail and charts of the charge of 2 heats are given. The casting properties of these various steels are discussed in detail, showing that the 3 groups behave differently in casting. The martensitic Cr and Cr-Ni steels with 13–15% Cr tend, when improperly deoxidized and with very low carbon content, to intercrystalline cracks. The truly ferritic 30% Cr and the semi-ferritic 18% Cr steels only tend to an orthotropic crystallization to a very small extent, and are not very sensitive to the cooling conditions. The austenitic Cr-Ni steels show a pronounced orthotropy. For rolling and forging all stainless steels must be thoroughly heated to 1100° C. The heat conductivity decreases from the martensitic to the austenitic steels, as given in the table below.

Carbon Steel	0.11 cal./° C. · cm. · sec.
Martensitic Steel	0.09 cal./° C. · cm. · sec.
Ferritic Steel	0.06 cal./° C. · cm. · sec.
Austenitic Steel	0.04 cal./° C. · cm. · sec.

Austenitic steels show the highest resistance to deformation in the group of stainless steels. The recrystallization temperature of austenitic steels is by 100–400° C. higher than that of the ferritic and martensitic steels, so that in using low rolling temperatures the austenitic steels can be strain hardened. In rolling stainless steels, a special design of the passes is necessary since these steels spread much more than other steels. The coefficients of spread are given for these steels, showing that the ferritic steels spread more than the martensitic and austenitic steels. All stainless steels can be cold-worked; austenitic steels can be strain hardened most. In deep drawing, the austenitic steels are unexcelled. Detailed information is given on the heat treatment of the stainless steels. Recrystallization diagrams have been established for the representative steels in all groups. As to the corrosion attack, reference is made to the recent publication by Strauss, Schottky and Hinnüber (*Zeitschrift für anorganische und allgemeine Chemie*, Vol. 188, Mar. 8, 1930, pages 309–324; *Metals & Alloys*, Vol. 1, Oct. 1930, pages 785–787). Difficulties in welding austenitic steels are discussed. Reference is made to development of stainless steels which are not impaired by welding. GN(3)

Comparison of the Physical Properties of Different Sections of Cast Iron and of the Standard Arbitration Test Bar. M. V. HEALEY. *Proceedings American Society for Testing Materials*, Vol. 30, 1930, part 1, pages 206–212.

Micro-Corrosion Tests on Aluminum and Aluminum-Alloys. (Mikrokorrosions-versuche an Aluminium und Aluminium-legierungen.) H. RÖHRIG. *Zeitschrift für Metallkunde*, Vol. 22, Oct. 1930, pages 362–364.

This paper delivered before the Deutsche Gesellschaft für Metallkunde, Berlin, 1930, presents evidence that the crystalline segregations are nobler than the surrounding matrix. Corrosion starts in the immediate vicinity of those segregated crystals. In the same manner the pure Al-plate on Al-alloys is attacked first, although Al turns out better if both layers are exposed to corrosive attack individually. The mechanism of the progressing corrosion is discussed as well as the influence of pores, pipes, inclusions and grain boundaries. By improving its purity, the crystalline segregations can be cut down materially and thus fewer weak spots are present. According to the author, the thermal treatment of Al and its alloys opens a wide, unexplored field with the object of improving the corrosion resistance. Röhrig kept track of the corrosion attack by means of a microscope. He used the following media: salt-water, with additions of hydrogen-peroxide, diluted organic acids and alkalies, formic acid, phenol diluted and pure. EF(4)

Corrosion-Prevention Methods as Applied in Aircraft Construction. H. S. RAWDON. *Proceedings American Society for Testing Materials*, Vol. 30, Pt. 2, 1930, pages 61–67.

Discussion appended. See *Metals & Alloys*, Vol. 1, Dec. 1930, page 901.(4)

Corrosion. (Korrosion.) Report of a Special Meeting of the Deutsche Gesellschaft für Metallkunde. PRZYGODE. *Elektrotechnische Zeitschrift*, Vol. 51, Sept. 4, 1930, pages 1278–1279.

Three principal questions were treated: (1) explanation of the corrosion phenomenon; (2) testing of metals for resistance to corrosion; (3) protection against corrosion by surface coatings. Recent investigations have proved that corrosion is an electro-chemical process, not a purely chemical one; phenomena, as forming of holes, de-zincing of brass, and formation of protective films on the surface prove this conclusively. This knowledge has led to several practical applications to make metals corrosion-proof by certain additions. Tests to determine resistance against corrosion should extend to determination of changes of surface, structure, and weight, and also those of mechanical properties. Measurements of tensile strength and particularly elongation have so far proved to be the most suitable, further bending tests and deepening tests. Certain test methods have been developed but none stand out as the best. With respect to sensitivity against influence of corrosion the properties can be taken in the following order: bending number, elongation, load, tensile strength, electrical resistance. Ha(4)

Rust-Proofing of Iron and Steel Products. CHARLES H. PROCTOR. *Metal Cleaning & Finishing*, Vol. 2, March 1930, pages 215–218, 231.

Outlines the development of black rust-proof coatings such as the Bower-Barff, Parker, and Coslett and Richards processes. Then gives solution formulas and operating details for electrodeposition of Zn, and the production of black protective coatings over the electrodeposited Zn. MS(4)

The Resistance of Electrodeposits to Corrosion, with Special Reference to Cadmium and Zinc. W. S. PATTERSON. *Metal Industry* (London), Vol. 36, May 16, 1930, pages 527–529; May 30, 1930, pages 579–582.

Corrosion of Riveting and Welding in Combustion Chemical Practice. (Die Korrosion an Niet- und Schweissstellen in der Brennstoffchemischen Technik.) O. GROSS. *Brennstoff-Chemie*, Vol. 11, Apr. 1, 1930, pages 133–134.

Responsibility of electrolytic action from acids and vapors reacting upon riveted and welded surfaces discussed. (4)

The Effect of Brines on Metals. (Die Einwirkung von Kühlsolen auf Metalle.) T. LIEPUS & H. OSTERBURG. *Metallwirtschaft*, Vol. 9, Nov. 7, 1930, pages 926–927 and Nov. 14, 1930, pages 946–948.

The action of chemically pure solutions of alkaline $CaCl_2$, neutral NaCl, alkaline NaCl and neutral $MgCl_2$ on Fe, Cu, Sn, Zn and Al is described, in regard to effect on the polish of the metals, their loss in weight and change of structure after metallographic examination. Curves showing loss in weight against time for 90-day immersions are given, grouped according to solutions and according to metals. Summarizing, these brines have the least effect on Sn. It is attacked slightly by the 2 alkaline solutions, but not by the others. Al is next best, then Zn. Fe is attacked the most, except by the 2 alkaline solutions. In choosing a brine the metals with which it comes in contact should be considered. Impurities in the solutions accelerate the attack on metals. Electrolytic action also takes place in the presence of 2 different metals. CEM(4)

Protective Coatings, Rust Protection and Coloring of Aluminum. (Ueberzüge, Rostschutz und Färbung des Aluminiums.) HERBERT KURREIN. *Metallwirtschaft*, Vol. 9, Dec. 5, 1930, page 1009; Dec. 12, 1930, pages 1031–1032.

Contains 9 references. Electroplating aluminum is more difficult than for other metals for several reasons. Al oxidizes very quickly when exposed to air. This oxide can be removed from pure Al by treating in HCl, HF or mixtures of the two, or in alkaline cleaners, such as Na_2CO_3–$NaHCO_3$ or NaCl–NaOH mixtures. Commercially impure Al and Al alloys cannot be cleaned in alkaline solutions as they leave a dark scum of insoluble impurities. These must be cleaned in acids. A slight etching is advantageous for plating, and for this reason sand blasting is practical. The high electrical potential of Al is another disadvantage and Al has a tendency to become covered with a loosely adhering coat of metal when immersed in the plating bath. This is best prevented by making Al passive previous to plating by dipping in concentrated HNO_3 at 60° C. for 5 minutes. This treatment also has the advantage of dissolving insoluble compounds after alkaline treatment. Al which has been made passive can be plated with Ni or Zn in acid solution, with Cd in cyanide and with Cu in H_2SO_4 or HNO_3 solution. Ag, Au, brass, or Cr can be plated over one of these metals. Ni is the best coating for Al. It can be applied without special previous treatment except degreasing in a special solution containing glycerin, at normal temperature with 0.5 amp./sq. dm., and 2–3 volts or at higher temperature with higher current density. In $^1/_2$ to 1 hour a dense, white coating of Ni is obtained which can be easily polished. Al can be Ni plated in ordinary solutions after making it passive in HNO_3, and dipping in weak alkaline cyanide and acid $FeCl_3$ solutions. Al cannot be plated with an adherent coating of Cu in cyanide solutions. A better process is to scratch-brush, dip in dilute alkali, then without rinsing in conc. HNO_3, plate in a solution of 100 g./l. $CuSO_4$ and 60 g./l. HNO_3 with 1–1.7 amps./sq. dm. at 1 volt for 10–20 minutes. For Zn plating Al should be sandblasted and after rinsing in water plated in 145 g./l. $ZnSO_4$, 35 g./l. sodium acetate and 1 g./l. gum Arabic. H_2SO_4 should be added to bring the pH to 4.0. Current density amps./sq. dm. This treatment gives very good corrosion resistance. CEM(4)

A Study of the Error of Averages and Its Application to Corrosion Tests. C. H. HUMES, R. F. PASSANO & ANSON HAYES. *Proceedings American Society for Testing Materials*, Vol. 30, Pt. 2, 1930, pages 448–455

Accurate Corrosion Test for Chrome-Iron Alloys. W. R. HUEY (E. I. du Pont de Nemours Co.). *Iron Age*, Vol. 126, Dec. 4, 1930, pages 1696–1698.

From a paper read before the National Metal Congress. Describes test developed in the laboratories of the E. I. du Pont de Nemours Co. VSP(4)

Steel Mains and Corrosion. E. E. JEAVONS & H. T. PINNOCK. *Gas Journal*, Vol. 191, July 23, 1930, pages 203–204; July 30, 1930, pages 255–256.

Steel mains properly bitumen coated, laid and earthed according to the authors' method, are subject to little or no electrolytic corrosion. A brief résumé is given of the Mond high pressure distribution system. A study was made of the electrolytic corrosion in this system of mains. Specifications are given for preventing electrolytic corrosion. Joints should be Cu bonded and at regular intervals wrought Fe earth bars should be welded to main. (4)

Effect of Carburizing Mixtures on Nickel-Chromium Alloy. M. A. HUNTER (Driver-Harris Co.). *Fuels & Furnaces*, Vol. 8, April 1930, pages 553–554, 560.

Energizers most commonly used in carburization are Na_2CO_3, $CaCO_3$, and $BaCO_3$. Tests carried out by J. J. Vreeland on the corroding action of the carbonates on Nichrome, showed only slight attack at 950° C. by Na_2CO_3 and completely negative results with $BaCO_3$ and $CaCO_3$. Tests were then made on the effect of adding a small amount of free S to the carbonates, with the following results.

Material	Temp. ° C.	Time in hrs.	Weight of Ni-Cr alloys in grams Before	After
Na_2CO_3 + S	950	.75	18.1395	14.6698
$BaCO_3$ + S	950	.75	16.6424	16.2842
$CaCO_3$ + S	950	.75	15.4692	15.4057

Experiments were then carried out with 6 commercial carburizing mixtures some of which contained as energizers, only Na_2CO_3, others only $BaCO_3$, and others mixtures of these with $CaCO_3$. Small pieces of Ni-Cr alloy packed in these mixtures in a Ni-Cr container and subjected to 1000° C. for 24 hrs. showed no appreciable attack. The outside of the container was corroded considerably, however, particularly where Na_2CO_3 was used. This material is lighter and more easily carried out of the box as dust than the other carbonates, the same being true of the dissociation products, the oxides. It reacts with the S of the fuel gases, and the mixture containing the sulphide, depositing on the exterior of the box, exerts a corrosive action on the Ni-Cr alloy. Some observations indicated that Zn vapor is very destructive at high-temperatures to both Ni and Ni-Cr alloys. MS(4)

Occurrence and Estimation of Lead and Zinc Compounds in Coal. *Iron & Coal Trades Review*, Vol. 121, July 18, 1930, page 80.

Abstract of a paper read before the Institution of Mining Engineers at Birmingham, July 9 by K. Neville Moss, A. A. Hirst, and L. W. Needham on the above subject. Two methods of examination were used: (*a*) spectroscopical; and (*b*) chemical. 11 samples were tested The results are summarized in the following table·

Material	Percentage Content of Lead	Tin	Zinc
Coal A	0.0032	Nil.	Nil.
Dirt-parting	0.024	Nil.	0.048
Coal B	0.025	Nil.	Nil.

These metals can cause trouble by promoting corrosion of boiler tubes. RHP(4)

Treatment of Airplane Parts to Prevent Corrosion. DENIS O'BRIEN (Fairchild Airplane Corp.). *Metal Cleaning & Finishing*, Vol. 2, May 1930, pages 431–432, 444.

An oil is forced into metal parts made of hollow steel tubing and is allowed to drain. Frame tubes and struts are cleaned by sand-blasting, coated with an oil-base oxide primer, and then fixed in spar varnish. Axles of landing gear, hydraulic members and wing fittings are first Cd plated and are also painted. Al parts are scratch brushed on a buffing wheel and are then coated with full-bodied oil-based Fe_2O_3 which is oven baked for 2 hrs. Exterior parts are then lacquered. Pontoons are made of duralumin. A commercial cleaner is used on these. Then a mist coat of an oil-base, air-drying oxide primer is applied, after which 2 coats of lacquer are applied. Interior of pontoons is treated with a coating of some commercial glyceride. MS(4)

Preservation of Highly Polished Surfaces. A. C. HANSON (Rock Island Arsenal Laboratory). *Industrial & Engineering Chemistry*, Vol. 22, June 1930, pages 603–604.

Results of tests on the effect of humidity on polished surfaces show that high humidity does not necessarily mean corrosion. Unless the moisture is deposited on the metal, there will be no corrosion. It is a matter of dew point and not humidity. MEH(4)

Contribution to the Evans Theory. (Beitrag zur Evansschen Belüftungstheorie.) E. HERZOG & G. CHAUDRON. *Korrosion und Metallschutz*, Vol. 6, Aug. 1930, pages 171–172; **Contribution to the Evans Theory,** E. MAAS & E. LIEBREICH. *Korrosion und Metallschutz*, Vol. 6, Aug. 1930, pages 172–173; **Distribution of the Corrosion Occurring under a Drop (Ueber die Verteilung der unter Tropfen entstehenden Korrosion.)** U. R. EVANS. *Korrosion und Metallschutz*, Aug. 1930, pages 173–174.

See *Metals & Alloys*, Dec. 1930, page 903. Continuation of the controversy on the value of the drop corrosion test and Evans' interpretation. In the first publication, the French authors report on experiments which can be satisfactorily explained by Evans' theory. Maass and Liebreich point out that the deductions of the French investigators are wrong. Evans' article refers to a paper previously abstracted in *Metals & Alloys*. EF(4)

The Problem of Condenser Tube Corrosion. D. HANSON. *Nickel Bulletin*, Vol. 3, Mar. 1930, pages 81–85.

A theoretical consideration of corrosion, discussing particularly the mechanism of condenser tube corrosion, the theory of electrolytic corrosion and the factors influencing corrosion. It is concluded that the solution of the corrosion problem lies in the use of corrosion-resistant alloys. The possibility of the use of Ni-Cu alloys is treated. Contains a schematic illustration of a jet test apparatus used for determining the comparative corrosion resistance of various condenser tubes. (4)

The Influence of Soluble Fluorides on the Corrosion of Iron. A. W. CHAPMAN. *Journal Chemical Society*, Vol. 133, July 1930, pages 1546–1550.

The corrosion of Fe (as foil) by KF and KCl solutions (with and without the addition of the inhibitors Na_2CO_3 and $KCrO_4$) is studied. Corrosion occurs in the same manner in 0.7 *N* KF and KCl solutions, continuing for higher KCl concentrations, but for 0.85 *N* (and above) KF solutions, the action ceases abruptly. It is suggested that this behavior of KF solutions is due to the formation of a protective film (probably a fluoride or double fluoride of Fe) on the metallic surface which prevents attack. Much less concentrated Na_2CO_3 and $KCrO_4$ solutions are required to inhibit the attack of dilute KF solution than of KCl solution of corresponding dilution, probably because the fluoride ion penetrates the protective film produced by the inhibitors less easily than the chloride ion. Solutions 0.1 *N* in KF and containing 0.05*M*–0.005*M* $KCrO_4$ cause the appearance of black spots on the surface of the Fe specimen, explained as the result of the interaction between FeF_3 (a primary corrosion product) and the chromate in the solution. STRUCTURE OF METALS & ALLOYS (5)

Metallography & Macrography (5a)

A New Etching Reagent for Nitrided Layers. (Ein neues Aetzmittel für Nitrierschichten.) O. HENGSTENBERG & F. BORNFELD. *Krupp'sche Monatshefte*, Vol. 11, Sept.-Oct. 1930, pages 265–266.

Since the etching solutions for nitrides as proposed by Fry and Comstock do not satisfactorily show the transitions of the various nitrided layers in a nitrided steel, the authors developed a new method which applies the following solutions: 1 g. HgCl + 20 cc. HCl + 80 cc. alcohol. This etching follows an etching with a solution of 10 g. $MgCl_2$ + 1 g. $CuCl_2$ + 40 cc. HCl + 100 cc. alcohol. In testing the hardness of a nitrided steel, it is shown that the various zones developed by the etching correspond to the hardness-depth curve. GN(5a)

Constitution of Nickel-Chromium Alloys. N. B. PILLING & T. E. KIHLGREN. *Transactions American Society for Steel Treating*, Vol. XV, June 1929, pages 1060–1061.

The constitution of the nickel-chromium alloys is discussed by N. B. Pilling and T. E. Kihlgren, in a data sheet prepared for the American Society for Steel Treating. In spite of the great industrial importance of these alloys, the information regarding their constitution is conflicting and, in some cases, of debatable value. The authors present an equilibrium diagram which attempts to reconcile the conflicting data previously published. (5a)

Constitution of Nickel-Copper Alloys. N. B. PILLING & T. E. KIHLGREN. *Transactions American Society for Steel Treating*, Vol. XV, June 1929, pages 1061–1062.

A short summary of the information available on the constitution of the nickel-copper series has been prepared for inclusion in the data sheet series of the American Society for Steel Treating. Copper and nickel crystallize in a face-centered cubic lattice, and the alloys form a simple series, with complete miscibility of the 2 elements both in the liquid and solid states. The nickel-copper equilibrium diagram reproduced in the sheet is that of Guertler and Tammann, fully confirmed by later workers. (5a)

Grain Growth in the Chrome-Irons. ARTHUR PHILLIPS & RALPH W. BAKER. *Iron Age*, Vol. 126, Nov. 27, 1930, pages 1588–1589, 1665.

From a paper read before the National Metal Congress. Experiments with steel containing 28% Cr and 0.25% C leads to the conclusion that steel of this composition is subject to rapid grain growth at temperatures, 1290° to 1830° F. and rapid growth at temperatures 1830° to 2550° F. Coarse structure is the cause of brittleness. VSP(5a)

Secondary Hardening in "Hyper-Hardened" Steels and the Stability of Austenite. (Trempe secondaire des aciers hypertrempés et stabilite de l'austenite.) P. CHEVENARD & A. PORTEVIN. *Comptes Rendus*, Vol. 191, Sept. 29, 1930, pages 523–525.

If steel be quenched under conditions which result in the suppression of both Ar′ and Ar″ points it will be retained in the austenitic state. In other words, it will be "hyper-hardened" (hypertrempé). So then, if, starting with a hypereutectoid steel in a completely "hyper-hardened" state, one lowers its carbon content by any means, one should observe the appearance first of Ar″ and then of Ar′; further, the occurrence of austenite in a particularly stable condition should be observed between the Ar″ and Ar′ points. Chevenard and Portevin have been able to generalize these conclusions and to extend them to the case of secondary hardening observed in a steel containing 1.5% and 2.0% Cr, which had been retained in the austenitic state as a result of quenching in water from 1180° C. Subsequent to the above treatment suitable samples of this steel were heated to a series of constant temperatures for 7 hours, during which time they were subject to examination—dilatation, micrographic, hardness, electrical resistivity and magnetic tests being made. At drawing temperatures below 330° or above 500° C. the phenomena observed by the authors in the case of this steel were identical with those they had previously noted and described in respect to a "hyper-hardened" 2.0% Mn hypereutectoid steel. Between 330° and 500° C., however, a profound perturbation was noted in the case of the Cr steel which was clearly related to the appearance of phenomenon absolutely different from that of secondary hardening. It appears that during drawing the retained austenite becomes decarburized as a result of the precipitation of a complex carbide and concurrently a certain proportion of the austenite transforms to ferrite and iron carbide. This proportion at first decreases with the drawing temperature; at about 330° C., however, the proportion becomes practically equal to unity, while the resistivity attains a maximum and the hardness a first maximum. The proportion then falls with increasing drawing temperatures, as is evidenced by the trend of the dilatation isothermals. After drawing at temperatures between 330° and 500° C., there still remains a certain amount of partially decarburized austenite. Commencing at 350° C. this austenite transforms into martensite on cooling with consequent production of the Ar″ point. On elevating the drawing temperature the amount of Fe_3C liberated during heating rises and the remaining austenite is increasingly decarburized. As might be expected, the Ar″ point and the amplitude of the quenching transformation (Ar″ transformation) increase, the resistivity and hardness rising to a pronounced maximum. Finally beginning at 430° C., the Ar′ transformation appears with production of troostite—the phenomenon of the doubling of the Ar point, as seen in quenching, is then observed (a fact which the authors believe has not been described hitherto). The double maximum in the hardness curve for this steel establishes the existence of 2 modes of hardening: (1) structural hardening, due to the change from austenite to ferrite plus cementite; (2) physico-chemical hardening, due to the formation of secondary martensite. Finally, it has been proved that a region of temperature exists above the Ar″ point where partially decarburized austenite is relatively very stable. OWE(5a)

The Macro Etching of Tin-Base Bearing Metals. ERNEST B. DRAKE. *Metals & Alloys*, Vol. 2, Jan. 1931, pages 20–24.

A method for macro-etching tin-base babbitts of various compositions has been suggested. The failures in connecting rod bearings which have been run in test engines appear most often in finely crystalline babbitts near the joint. The macro-etched babbitts indicate fairly well the size and distribution of the micro constituents which may be expected. Centrifugally cast main- and connecting-rod bearings show SnSb cubes are absent, all imbedded in a ground mass of tin-rich eutectic when the babbitt is of the type: 85% Sn, 7.5% Sb, 7.5% Cu. The die cast main- and connecting-rod bearings show no SnSb cubes but do show a larger amount of CuSn needles imbedded in a ground-mass of tin-rich eutectic and δ-solid solution when the babbitt is of the type: 85% Sn, 7.5% Sb, 7.5% Cu. ESC(5a)

The Photographing of Cooling Curves. H. D. CROCKFORD & A. E. HUGHES. *Journal of Physical Chemistry*, Vol. 34, Nov. 1930, pages 2624–2626.

Authors describe a simple apparatus developed by them for recording cooling curves of mixtures of certain nitrotoluenes and benzoic acid, the freezing points of which could be checked to 0.1° C. with those obtained from direct galvanometer readings. The apparatus could be readily applied to metallographic work. OWE(5a)

Automatic Preparation of Metallographic Samples. R. G. GUTHRIE & J. A. COMSTOCK. *Metals & Alloys*, Vol. 1, Sept. 1930, pages 727–730.

Fundamental considerations, operation of polishing machine, advantages of automatic preparation are discussed. (5a)

Iron-Aluminum-Carbon Alloys. (Beitrag zur Kenntnis der Eisen-Aluminium-Kohlenstoff-Legierungen.) O. VON KEIL & O. JUNGWIRTH. *Archiv für Eisenhüttenwesen*, Vol. 4, Oct. 1930, pages 169–175; *Stahl und Eisen*, Vol. 50, Nov. 20, 1930, page 1643.

The influence of Al on the systems iron–graphite and iron–cementite was studied. In melting Swedish soft Fe, the C was introduced by electrode graphite and technically pure Al was finally added. The results show that, for an Al content of 2–3%, practically all C is present as graphite. In increasing the amount of Al up to 11%, graphite disappears completely but, on further increase of the Al content to 18%, all C is again present as graphite. The eutectic temperature of Fe-C alloys is gradually increased with the increasing Al content so that this temperature amounts to 1300° C. for 14% Al. Above this content, the eutectic temperature is again lowered; 1% Al diminishes the eutectic C concentration by 0.16% C. The temperature of the pearlitic transformation is somewhat lowered up to 3.5% Al, but rises again above this concentration up to 8% Al. Detailed reference is made to the structures occurring in the alloys investigated. 2 new phases were observed in these alloys. GN(5a)

Coarse Crystallization of Aluminum. (Die Grosskristallisation von Aluminium.) R. KARNOP & G. SACHS. *Mitteilungen der deutschen Materialprüfungsanstalten*, Sonderheft 13, 1930, pages 94–98.

The Molecular Constitution of Certain Intermetallic Solid Solutions at Temperatures below that of the Eutectic Examined Thermodynamically. F. H. JEFFERY. *Transactions Faraday Society*, Vol. 26, Oct. 1930, page 587; **The Molecular Constitution of the Solid Solution of Tin in Lead at Temperatures Below the Eutectic.** F. H. JEFFERY, pages 588–590.

These two papers can be considered together. The former shows that the equation of equilibrium of the phases along the boundary from the end of the eutectic isothermal for decreasing temperatures is:

$$\log (1 - n') - \log n = \frac{\lambda}{R\Theta} + \left((\log K\theta_1 - \frac{\lambda}{R\Theta_1}\right)$$

where n = the molal fraction of Y in X for the first phase and n′ = the molal fraction of X in Y for the solid solution formed in the second two-phase system (the other symbols have their usual thermodynamic meanings). Now, if the molecular aggregations of the two components X and Y in each of the solid solutions be chosen suitably [log (1 — n′) — log n] is a linear function of $1/\theta$. Inasmuch as both solid solution boundaries are involved, it is almost certain that if a solution can be found it is unique. Hence, the molecular constitution of the solid solution at these temperatures can be found. The second paper shows that the above equation can be applied to the case of the solid solution of tin in lead from 180° to 130° C. and that, as a result, the assumption that an isothermal exists at 145° to 150° C. is untenable. What a Heat Treater Should Know about Physical Chemistry. GEORGE M. ENOS (University of Cincinnati). *Fuels & Furnaces*, Vol. 8, March 1930, pages 321–326.

Brief discussion of the gas laws, phase changes, and equilibrium diagrams. MS(5a)

A New Macroscopic Etching Reagent. *Metallurgist*, Sept. 1929, pages 142–143.

Brief review on the article by G. d'Huart in the June, 1929, issue of *Revue de Metallurgie* about the new etching reagent. See *Metals & Alloys*, Oct. 1929, page 179. (5a)

A Micro-Furnace for Temperatures above 1000°. H. S. ROBERTS & G. W. MOREY. *Review of Scientific Instruments*, Vol. 1, Oct. 1930, pages 576–580.

The furnace consists essentially of a bare strip of platinum-rhodium bent into a U and electrically heated. An optical pyrometer is sighted down into the bottom. Discussion of accuracy and limitations of the strip for investigations of phase relations and melting points at high temperatures. Advantages of this type of micro-furnace are: reaching very high temperatures, almost instantaneous heating and cooling, and light weight and consequent inexpensiveness of strip. Major sources of error are: differences of temperature between top and bottom of charge, and uncertainties in constancy of relation between brightness temperature and true temperature of strip. Upper temperature limit for single-thickness platinum-40% rhodium strip is about 1850° C. MFB(5a)

Structure & X-ray Analysis (5b)

An X-ray Analysis of the Copper-Manganese Alloys. (Röntgenanalyse der Kupfer-Manganlegierungen.) ELIS PERRSON. *Zeitschrift für physikalische Chemie*, Abt. B, Vol. 9, July 1930, pages 25–42.

An X-ray crystallographic analysis of the Cu–Mn system is reported and the possibility discussed of a continuous transition of the Cu-phase into the γ-Mn-phase with increasing Mn content. It is shown that the γ-Mn-phase, ordinarily stable at high temperatures only, becomes stable at ordinary temperatures when alloyed with small amounts of Cu and chilled. The boundary of this phase occurs with concentrations of 83 atomic % Mn. The lattice parameter of the Cu-phase increases with increasing Mn content, from 3.008 to 3.74 A. U. with 50% Mn, then remains constant to the phase boundary. The atomic volume in both simply built phases appears to change continuously over the entire system. Alloys consisting of these phases are formed with considerable expansion. (5b)

X-ray Testing of Aircraft Materials. ANCEL ST. JOHN. *Proceedings American Society for Testing Materials*, Vol. 30, Pt. 2, 1930, pages 147–149.

Discussion appended. See *Metals & Alloys*, Vol. 1, Nov. 1930, page 845. (5b)

Measurements of Elasticity with X-Rays. (Elastizitätsmessungen mit Röntgenstrahlen.) G. SACHS & J. WEERTS. *Zeitschrift für Physik*, Vol. 64, Aug. 28, 1930, pages 344–358.

The change of the lattice constant of a "Duralumin" rod of oblong rectangular cross-section, on bending on the convex side is found to be proportional to the sagging. The ratio of the main dilatations is found from the spectrogram. Precision of the lattice constant is $\pm 3.10^{-4}$ A. U. (5b)

Application of Refraction of Electrons. (Ueber Anwendung der Elektronenbeugung.) E. RUPP. *Forschung und Technik*, 1930, pages 18–22.

For testing the structure of materials, X-rays have taken a dominant position when the space lattice is to be determined. For determining the surface structure and lattice, electrons are used with much greater advantage because of the smaller degree to which they penetrate into the material. Pictures can be made in a few seconds while exposures with X-rays require hours. The method uses electron velocities of 5000 volts and more. The tubes used and the practical application are described and some results of measurements of gas inclusions in metallic surfaces, chemical reactions of catalytic surfaces and glow-electrically and light-electrically acting surfaces. The results are illustrated by curves and diagrams. Ha(5b)

Practical Experiences in Hardness Testing. B. BROWN. *American Machinist*, Vol. 73, Oct. 23, 1930, pages 651–654.
Discussion by C. H. Wilson, Wilson-Maeulen Co., Inc., *American Machinist*, Vol. 73, Oct. 30, 1930, page 693. There are 4 types of hardness testing machines: (1) Indentation, such as the standard Brinell, Brinell Comparator, Pyramid, Rockwell, Alfred Herbert and Hardometer; (2) rebound machines, such as Scleroscope, and the Alpha Rebondimeter; (3) ductility machines of the cupping variety, such as Erichsen, and the Erichsen-Olsen; (4) others, including Herbert Pendulum, and the cloudburst. Brinell was the first really successful machine. Measurement of depth of indentation is usually more accurate than the diameter. Cold weather gives increased oil viscosity and often erroneous results arise. Time of application of load and ball size often lead to errors. Etched balls make the microscope work more accurate. Brinell Comparator gives a rough estimate of hardness when used by an experienced man. It is of no value for thin sheet metal. Rockwell machine uses a different scale from that of the Brinell and causes confusion. It is not good for material less than 0.04 in. thick unless the material is very hard. The Pyramid tester appears to be the only indentation machine which may be used on very thin sheet. The Herbert machine is suited for rough work. It cannot well be used on hard metals. The Scleroscope is not good for any but flat surfaces and cannot be used on thin material. The Alpha Rebondimeter has about the same characteristics as the Scleroscope. Imperfections in the surface are more likely to throw the ball sideways. Erichsen is valuable where much press work is done. It gives 3 sources of information: (1) depth of cup; (2) dome macrostructure; (3) type of the burst. Does not measure force required for drawing. The Erichsen-Olsen machine is similar to the last but it measures force required for drawing also, up to 12,000 lbs. The Pendulum machine gives reliable results, readily convertible to Brinell scale. It also measures the potentialities of a metal for work hardening. The Cloudburst tests uniform hardness without damaging the surface. By reducing impacts so that the ball impressions do not overlap, the indentations may be measured and results converted to Brinell. Briefly gives principle and operation of each of the above mentioned machines. Discussion: Admits the confusion due to difference in Rockwell and Brinell scales. Discusses why the Rockwell machine could not use Brinell scale, and indicates that the Rockwell scale in actual practice is as accurate as the Brinell. Also that it has a place in testing which cannot be taken by the Brinell tester. RHP(6)

Practical Testing of Sheet and Strip for Drawing Operations. L. N. BROWN. *Metal Stampings*, Vol. 3, March 1930, pages 239–242, 270.
Cup tests are usually made to determine drawability of sheets. On material up to 0.0625 in. thick, standard practice is to use a $^7/_8$ in. ball or plunger with a 1 in. diameter die with standard radius, and standard width test piece. On heavier material most satisfactory results are obtained using the standard ball and a 2 in. die. A testing machine has been developed which measures the load necessary to make cups of certain depths, as well as the depth of cup. Samples 3 in. wide are used on tests of 0.0625 in. or under, while samples $4^1/_2$ in. wide are used for heavier sheets. In testing, the load necessary to make an impression 0.1 in. or 0.25 in. deep is measured, together with depth at which the sample breaks, and the thickness of the material. All tests should be made under the same conditions. Other tests such as the various hardness tests and the tensile test are also employed. Presents some typical results obtained. MS(6)

Hardness by Mutual Indentation. IRVING H. COWDREY. *Proceedings American Society for Testing Materials*, Vol. 30, Pt. 2, 1930, pages 559–571.
Includes discussion. See *Metals & Alloys*, Vol. 1, Nov. 1930, page 847. (6)

The Relation between Sheet Thickness and Depth of Impression by the Erichsen Method. (Die Wirklichen Beziehungen zwischen der Blechdicke und Erichsentiefung.) K. DAEVES. *Stahl und Eisen*, Vol. 50, Oct. 23, 1930, page 1501.
Since the present known standard curves of the Erichsen method showing the relation between sheet thickness and depth of impression are unreliable, particularly for thin sheets, the author evaluated the results of 4000 tests to determine the true relations. As a result, it is shown that the depth of impression is not proportional to the thickness of the sheet but proportional to the logarithm of the sheet thickness according to the equation: depth of impression = 6.36 × log. sheet thickness ÷ 10.83 mm. GN(6)

The Wear of Rails. (Die Verformungsabnutzung der Schienen.) N. DAWIDENKOW. *Stahl und Eisen*, Vol. 50, Nov. 6, 1930, pages 1580–1584.
A new method to test the wear resistance of rails which determines the wear resistance by deformation tests is described. The diameter of a ball impression is chosen as the unit of the deformability. The ball pounds repeatedly against the surface of the rail under certain conditions. In comparing the results of this test on 109 rails, it is shown that the new method gives a reliable basis from which to predict the practical behavior of rails from laboratory tests as far as the resistance against deformation is concerned. GN(6)

Theory of Wear. (Ueber die Abnutzungtheorie.) H. FRIEDRICH. *Maschinenbau*, Vol. 9, Feb. 20, 1930, pages 129–131.
Comparison is made between abrasion by friction and by machines: grinding, filing, sawing, etc. The explanation for the wear theory is based upon these comparisons. Experiments are made on an abrasion-testing machine. Calculated and measured values are compared. (6)

Photo-Elastic Studies of Aircraft Parts. T. H. FROST. *Proceedings American Society Testing Materials*, Vol. 30, Pt. 2, 1930, pages 150–153.
Discussion appended. See *Metals & Alloys*, Vol. 1, Nov. 1930, page 846. (6)

A Furnace for High Temperature Tensile Tests. (Beschreibung eines Zerreissofens.) O. HOLTSCHMIDT. *Mitteilungen aus den Forschungsanstalten des G.-H.-H.-Konzerns*, Vol. 1, Nov. 1930, pages 40–44.
An electrically heated fused salt-bath furnace for tensile tests up to 700° C. is described, in which the specimen is immersed in the bath. Not over 6° C. difference in temperature exists between the middle and ends of the specimen. A Martens' mirror extensometer is used. The mirrors are removed before fracture of the specimen; the rest is left in the bath. Fittings are illustrated for use when testing tubing. HWG(6)

Offers Some New Hardness Tables. T. N. HOLDEN, JR. (E. W. Bliss Co.). *Iron Age*, Vol. 126, Oct. 2, 1930, page 932.
Describes 2 hardness tables. One of the tables deals with Brinell hardness using a 5 mm. ball with 750 and 250 kg. load. The other table shows Brinell hardness numbers using a 10 mm. ball with 3000, 1000, and 500 kg. load. VSP(6)

Army Arsenal Tests Experimental Welds. J. B. ROSE. *Welding*, Vol. 1, Oct. 1930, pages 832–834.
Results of experiments conducted at the U. S. A. arsenal at Watertown, Mass. on fatigue and impact values for welds. 6 tables summarize the data. W(6)

Proper Heat Treatment Reduces Stress-Corrosion Cracking of Brasses. ALAN MORRIS. *Fuels & Furnaces*, Vol. 8, July 1930, pages 935–936, 946.
From paper read before the American Institute of Mining & Metallurgical Engineers. See *Metals & Alloys*, Vol. 1, Apr. 1930, page 473. MS(6)

Inspecting Bar Stock by Magnetic Analysis. R. R. MOORE. *Machinery* (N. Y.), Vol. 36, May 1930, pages 672–673.
A brief description of etching test and functioning of magnetic flaw detector. Oscillogram for bar containing crack is shown; approximate size of crack is indicated diagrammatically. A summary of advantages is given. See *Metals & Alloys*, Vol. 1, July 1930, page 629. (6)

Creep Stress Determination. *Metallurgist*, Feb. 1930, pages 22–23.
A review of the work of W. Rohn on the correct determination of the limiting creep stress of materials working for long periods at high temperatures. Among the materials considered: Alloy of 16% Fe, 60% Ni, 15% Cr, 7% Mo and 2% Mn, annealed at 1050°. (6)

The Unbalanced Alternating Current Bridge for Magnetic Analysis. W. B. KOUWENHOVEN & A. C. SELETZKY. *Proceedings American Society for Testing Materials*, Vol. 30, Pt. 2, 1930, pages 298–312.

Influence of the Specimen Shape on the Notch Toughness of Sheets of Various Composition and Heat Treatment. (Einfluss der Probenform auf die Kerbzähigkeit von Grobblechen verschiedener Zusammensetzung und Wärmebehandlung.) F. KÖRBER & K. WALLMANN. *Mitteilungen Kaiser Wilhelm Institut für Eisenforschung*, Vol. 12, 1930, pages 193–202, Report 157; *Stahl und Eisen*, Vol. 50, Dec. 4, 1930, page 1724.
The authors investigated the suitability of various notch bar specimens in order to determine the influence of the shape on the data of heat treated sheets. Four different structural steels were used for the investigation. Sheets in 3 thicknesses, between 10 and 30 mm., were rolled at 3 different temperatures between 700° and 900° C., annealed partly above and partly below the A_3 point, either cooled in the furnace or on the floor. Other samples were quenched and drawn, and tested. GN(6)

Mechanical Testing of Aircraft Materials. J. B. JOHNSON. *Proceedings American Society for Testing Materials*, Vol. 30, Pt. 2, 1930, pages 119–126.
Discussion appended. See *Metals & Alloys*, Vol. 1, Nov. 1930, page 846 (6)

Fracture of Notched Tensile Tests. (Der Bruch Gekerbter Zugproben.) W. KUNTZE. *Mitteilungen der deutschen Materialprüfungsanstalten*, Vol. 14, 1930, pages 7–16.

Internal Stresses in Hollow Cylinders of Tool Steel Estimated. O. V. GREENE (Carpenter Steel Co.). *Iron Age*, Vol. 126, Nov. 13, 1930, pages 1378–1380.
Taken from a paper read before the American Society for Steel Treating. Describes 2 methods of determining internal stresses in hollow cylinders of carbon tool steel. Relative advantages are pointed out. VSP(6)

Fatigue Strength and Resistance to Slip. (Schwingungsfestigkeit und Gleitwiderstand.) P. LUDWIK. *Zeitschrift für Metallkunde*, Vol. 22, Nov. 1930, pages 374–378.
Fatigue tests were performed paralleling tensile and hardness tests in order to throw light upon the correlation of endurance properties with elastic limit, maximum tensile strength, reduction of area and hardness. Hardness measurements during the fatigue test were carried out and yielded an increase of 65% in case of electrolytic copper, presumably the metal was stressed to the same degree as given by the fatigue strength value. At lower or higher stresses, this maximum hardness could not be attained. Further endurance tests refer to polished and notched test rods of various materials and some experiments were carried out with sea-water dropping upon the test pieces in order to study the corrosion endurance strength. Endurance bending and torsion tests with polished test rods yielded a ratio between torsion and bending strength of 0.575 ± 6%. The same ratio holds for the yield point values from torsion and tension (compression) stress in the case of static load. A larger ratio of 0.929 ± 6.16 was obtained on cast iron due to the notching effect of graphite. In spite of equal degrees of grooving the sensitiveness to torsion amounted to only 0.575 of the bending value. Owing to this the torsion fatigue strength of turned or notched test bars compared with their bending endurance strength is higher than in test pieces with a polished surface. EF(6)

The Danger of Fracture in Metallic Materials. (Die Bruchgefahr bei metallischen Werkstoffen.) W. KUNTZE. *Mitteilungen der deutschen Materialprüfungsanstalten*, Sonderheft 14, 1930, pages 60–61. Also in *V. d. I. Nachrichten*, Vol. 9, No. 49, 1929.
Further comment on the importance of "technical cohesion strength" (Trennfestigkeit). Very general discussion. (6)

Calculation of Vibration Strength from Tensile Strength and Elastic Property. (Berechnung der Schwingungsfestigkeit aus Zugfestigkeit und Trennfestigkeit.) W. KUNTZE. *Mitteilungen der deutschen Materialprüfungsanstalten*, Vol. 14, 1930, pages 82–85.

Magnetic Testing of Steels. (Die magnetische Prüfung von Stählen.) KUEHNEL & PUSCH. *Zeitschrift Verein deutscher Ingenieure*, Vol. 74, Nov. 12, 1930, page 1521.
More recent methods use, instead of direct current, alternating current and an oscillograph for both indicating and recording. In this way, defects, heat treatment, hardness, inclusions, segregations, etc. can be determined as well as the quality of welded seams. The instrument is built by the Magnetic Analysis Corp., Long Island City, N. Y. A few records are given. Ha(6)

ELECTRO-CHEMISTRY (7)

Electroplating (7a)

Cadmium as an Electroplated Coating. (Kadmium als galvanischer Ueberzug.) HERBERT KURREIN. *Chemiker Zeitung*, Vol. 54, April 30, 1930, pages 333–335.

Contains 17 references. A review and discussion of the development of Cd plating. CEM(7a)

Artistic Finishes on Floor Lamps and Lighting Fixtures. MEYER ROTOR. *Metal Stampings*, Vol. 2, Jan. 1930, pages 39–40, 52; Feb. 1930, pages 139–140, 170.

Solution formulae and operating details for imparting to brass and bronze parts such finishes as acid bronze, English bronze, antique English bronze, Flemish bronze, Flemish brass, and oxidized silver. MS(7a)

Electrodeposition of Uncommon Metals. D. B. KEYES & S. SWANN, JR. (University of Illinois). *Metal Cleaning & Finishing*, Vol. 2, May 1930, pages 415–416.

Abstract of a bulletin of the University of Illinois Engineering Experiment Station. See *Metals & Alloys*, Vol. 1, July 1930, page 630. MS(7a)

Control of Copper Cyanide. WALTER M. PINNER & EDWIN M. BAKER. *Metal Cleaning & Finishing*, Vol. 2, June 1930, pages 511–512.

Abstract of paper read before American Electrochemical Society, May 29–31, 1930. See *Metals & Alloys*, Vol. 1, Oct. 1930, page 797. MS(7a)

Use of Insulated Racks for Electroplating. *Metal Cleaning & Finishing*, Vol. 2, June 1930, pages 497–498.

A recent development in racks for suspending parts in the plating tank is one having the spine coated with a special corrosion-resisting compound which insulates it from contact with the electric current. Its use effects savings of metal, labor, and current. MS(7a)

Lead Anodes for Chromium Plating. L. C. PAN (College of the City of N. Y.). *Metal Cleaning & Finishing*, Vol. 2, May 1925, pages 405–408; June 1925, pages 503–506.

Pb has been found to be a superior material for insoluble anodes for Cr plating, and is most generally used. Steel is the only other material being used in any appreciable quantity. Advantages of Pb are that it does not seriously affect the metal content of the bath; if proper care is taken, it is insoluble in CrO_3 and has long life; it admits no impurities to the bath; and it maintains a low trivalent Cr content in the bath. Pb anodes have a high O over-voltage due to the fact that a film of PbO_2 forms over the entire surface as soon as they are put into operation. This film reoxidizes the trivalent Cr back to the hexavalent form, thus maintaining the proper composition of the bath. If Pb anodes are left in the bath when not operating, $PbCrO_4$ will be formed on the surface which will shorten the life of the anode and will necessitate the use of higher voltages. Proper care of the anodes requires that the current be turned on the anodes immediately after putting new ones in the bath; and every day, as soon as the day's plating is done, they should be removed from the bath, rinsed in H_2O, wiped off with a soft brush or sponge, and allowed to dry in air over night. After more than 6 weeks time, it is not necessary to clean the anodes every day. Anodes made of 6% Sb and 94% Pb differ from pure Pb anodes in that they are less soluble in Cr plating solutions, form less $PbCrO_4$ while idle in solution, form less PbO_2 while in operation, are harder, and have more strength. Simplest way to connect anode body to the anode bars is to attach a Pb-coated Cu hook to the anode body by means of bolts and nuts. Anodes are best made in narrow strips 4 in. wide, $^3/_{16}$ in. thick, and long enough to reach 4–6 in. from the bottom of the tank, and should be arranged so that there will be a space of 3–4 in. between adjacent anodes. Each hook should give contact on the anode bar at 2 points. Anode current density should be lower than the cathode current density. MS(7a)

Production of Imitation Pewter and Flemish Iron Finish on Brass and Copper Parts. CHARLES H. PROCTOR. *Metal Cleaning & Finishing*, Vol. 2, April 1930, pages 307–309.

Describes cleaning, plating, and polishing operations, and gives solution formulae. MS(7a)

Electrodeposition of Tin. CHARLES H. PROCTOR. *Metal Cleaning & Finishing*, Vol. 2, Feb. 1930, pages 117–120, 136.

Operating details and solution formulae for coating metal articles by the boiling process and by electrodeposition. Outlines uses and applications of Sn as a protective coating. MS(7a)

Electroplaters' Handbook. CHARLES H. PROCTOR. *Metal Cleaning & Finishing*, Vol. 2, Jan. 1930, pages 71–74; Feb. 1930, pages 167–170; March 1930, pages 257–260; April 1930, pages 347–350; May 1930, pages 441–444; June 1930, pages 541–543; July 1930, pages 633–637; Aug.1930, pages 717–720; Sept. 1930, pages 805–808; Oct. 1930, pages 887–890.

Collection of receipts and formulae, with operating details, for the deposition of Al, Sb, As, brass, bronze, Cu, Cd, Co, Cr, Au, Fe, Pb, Ni, Pd, Pt, rust-proof deposits for Fe and steel, Au, Sn, and Zn; various colors and finishes on metals; pickling; silvering glass mirrors; and dips and matts. MS(7a)

Preparation and Chemical Control of Brass Plating Solutions. CHARLES H. PROCTOR. *Metal Cleaning & Finishing*, Vol. 2, Jan. 1930, pages 25–30.

Gives typical plating bath formulae and operating details. Deals with anode composition and reducing agents. Outlines method of chemical analysis. MS(7a)

Electrodeposition of Nickel for Chromium Plating. SAMUEL GORDON. *Metal Cleaning & Finishing*, Vol. 2, April 1930, page 310.

To prevent peeling of Ni deposit even though imperfectly cleaned the following solution is recommended: 1 gal. H_2O, 6 oz. $NiSO_4$, 2 oz. $NiSO_4$-$(NH_4)_2SO_4$, 1 oz. $NiCl_2$, 1 oz. $MgSO_4$, 1 oz. H_3BO_3, $^1/_2$ oz. Ni F_2. Cast brass or bronze articles should be flash plated in $Cu(CN)_2$ solution prior to Ni plating. Bath must be kept up to full working capacity by periodical additions of 1 oz. $NiSO_4$, $^1/_2$ oz. $NiCl_2$ and $^1/_{16}$ oz. NiF_2/gal. of solution. MS(7a)

The Electro-Deposition of Cobalt-Nickel Alloys. Part I. S. GLASSTONE & J. C. SPEAKMAN. *Transactions Faraday Society*, Vol. 26, Oct. 1930, pages 565–574.

The compositions of the alloys deposited from well-buffered solutions of definite H-ion concentration containing various proportions of cobalt and nickel sulphates have been studied at a series of current densities ranging from 0.0028 to 5–6 amp./sq. dm. At low current densities the compositions of the deposits are almost independent of (1) the current density; (2) the dilution of the solution; and (3) stirring. Beyond a certain current density the Co content of the deposits decreases; the deposits always contain relatively more Co than do the electrolytes. The former phenomenon has been correlated with the impoverishment of the catholyte in cobalt ions, occasioned by the latter phenomenon. Dilution of the electrolyte emphasizes the former phenomenon; stirring tends to eliminate it. The composition of the initially deposited alloys is independent of the H-ion concentration of the electrolyte; the current efficiency for metal deposition increases with increasing pH and the effect of impoverishment of the electrolyte appears at lower current densities. Acetate ions do not appear to affect the relative tendencies for Co and Ni to deposit from solutions of mixed suphates. The paper concludes with a comparison of Co-Ni with Fe-Ni depositions. OWE(7a)

Platinum Plating for Repaired Weights. *Metal Industry* (N. Y.), Vol. 28, Aug. 1930, page 380.

From Technical News Bulletin of the Bureau of Standards. VSP(7a)

Silver Plating Small Brass Articles by Immersion. CHARLES H. PROCTOR. *Metal Cleaning & Finishing*, Vol. 2, May 1930, pages 411–412.

Describes procedure employed, including operating details and solution formulae for cleaning, acid and cyanide dipping, Ag immersion, and final cleaning and lacquering. MS(7a)

Variation in Thickness of Nickel Deposits. LELAND E. & VERNON E. GRANT (New Departure Mfg. Co.). *Metal Industry* (N. Y.), Vol. 28, June 1930, pages 275–276; July 1930, pages 325–327.

Gives results of experiments to determine variation in thickness of Ni deposit on articles plated in various parts of one tank. Also how much the pieces in one tank varied from those in other tanks. Plating solution was of following composition:

Single nickel salts	16 oz./gal.
Ammonium chloride	2 oz./gal.
Boric acid	2 oz./gal.

Three types of anodes used. These were cast, electrolytic and heat treated rolled anodes. Attempt was made to hold pH between 5.6 and 6.1. Current density was about 5 amps./ft.^{2} Thickness of deposit was measured, first, through a microscope and, secondly, by weighing amount of deposited Ni. Contains table giving results of measurements of 64 specimens. Another table gives results of measurement made on specimens plated in a double salt solution of the following composition:

Double nickel salt	10 oz./gal.
Ammonium chloride	2 oz./gal.
Boric acid	2 oz./gal.
Epsom salts	2 oz./gal.

As a result of experiments, the following conclusions are justified: (1) similar articles plated simultaneously in single Ni salt solution do not have uniform deposits; (2) pieces at the bottom of the rack usually have the thickest deposit. VSP(7a)

Preliminary Study of the Electro-Deposition of Metals from Liquid Ammonia Solutions of Their Salts. L. F. AUDRIETH & L. F. YNTEMA. *Journal of Physical Chemistry*, Vol. 34, Sept. 1930, pages 1903–1906.

As a result of experiments involving the electrolysis of cyanides, iodides and nitrates of a number of metals, the authors conclude that the phenomena of electro-deposition of metals from liquid ammonia solutions of their salts closely parallels the behavior of the corresponding aqueous solutions. They question whether the use of liquid ammonia as a solvent will lead to the desposition of metals which have not yet been discharged from aqueous solution. OWE(7a)

The Production of Continuous and Seamless Tubing by Electrodeposition. JEAN BILLITER. *Metal Industry* (N. Y.), Vol. 28, Aug. 1930 pages, 378–380.

Paper presented before the Electrochemical Society at St. Louis, May 29–31, 1930. Describes 2 methods of making Cu and Fe tubing. See *Metals & Alloys*, Vol. 1, Oct. 1930, page 796. MS(7a)

Electro-Deposition of Metallic Beryllium. HAROLD SIMMONS BOOTH & G. G. TORREY. *Journal American Chemical Society*, Vol. 52, June 1930, pages 2581–2582.

Communication to the Editor. The authors announce that they have been successful in obtaining Be by the electrolysis of solution of Be salts in various inorganic and organic non-aqueous solvents. The metal so deposited is insoluble in the strongest acids unless the metal is in contact with a more electro-negative metal like Pt. Dehydrated Be salts may be electrolyzed in liquid ammonia and the metal obtained. MEH(7a)

Airtight Joints by Electroplating. J. B. CALVA (Baeder Adamson Co.), *Chemical & Metallurgical Engineering*, Vol. 37, July 1930, page 445.

A cast-iron waste-heat evaporator, in which the tubes were electrically welded to the headers, would not hold a vacuum, as the welds were not airtight. Fe rings $^1/_4$ in. in diameter were placed around each of the welds, concentric with the tubes. Small pieces of rubber held the rings in place and insulated them. The rings were interconnected with Cu wire, and a piece of wire passed through a watertight wooden cover which was bolted to the flange. An electrolyte made up of $FeCl_2$, $CaCl_2$, and H_2O was poured into the tubes, covering the rings and welds. The electric welding machine was adapted for electrolytic work, the current being limited to 15–20 amp./dcm.^{2} The positive terminal was connected to the Cu wire from the rings and the negative, to the evaporator. After 24 hrs. of electrodeposition, the maximum expected vacuum was obtained. MS(7a)

Effect of Addition Agents on Acid Copper Plating Solutions. B. CLARK & E. O. JONES. *Metal Cleaning & Finishing*, Vol. 2, March 1930, page 232; April 1930, pages 319–320.

Paper presented before Electroplaters' and Depositors' Technical Society and the Faraday Society. See *Metals & Alloys*, Vol. 1, July 1930, page 630. MS(7a)

Burnishing and Nickel Plating Kitchen Utensils. T. C. EICHSTAEDT. *Metal Industry* (N. Y.), Vol. 28, Oct. 1930, page 478.

Discusses the burnishing and plating of steel articles such as spoons, egg separators, beaters, turners, strainers, ladles, etc. Deals with ball burnishing of stainless steel. Gives solutions for burnishing and barrel plating. VSP(7a)

Electrometallurgy (7b)

Electrolytic Recovery of Lead from Lead Sulfate Waste. COLIN G. FINK & LAWRENCE GREENSPAN. *Canadian Mining Journal*, Vol. 51, Oct. 10, 1930, pages 974–976.

See *Metals & Alloys*, Vol. 1, Dec. 1930, page 911. (7b)

Manganese in Electrolytic Zinc Practice. OLIVER C. RALSTON (United Verde Copper Co.). *Engineering & Mining Journal*, Vol. 130, Oct. 23, 1930, pages 375–378; Nov. 24, 1930, pages 510–512.

An analysis of available data and a critical study of the evidence that formed a considerable part of the testimony in the case of Electrolytic Zinc Process vs. French's Complex Ore Reduction, hinging on the validity of a Canadian patent. WHB(7b)

Investigation of the Influence of Current Density and Temperature upon Commercial Zinc Electrolysis. (Untersuchungen über den Einfluss von Stromdichte und Temperatur auf die technische Zinkelectrolyse.) P. RÖNTGEN. *Metall und Erz*, Vol. 26, Dec. 1929, pages 617–624; correction, Vol. 27, Jan. 1930, page 34.

Contains 2 references. The influence of current density and composition of acid Zn solutions on the H overvoltage are discussed. Higher current density can be used only with higher Zn concentration and this is limited by the solubility of Zn in dilute H_2SO_4. The influence of current density and temperature on current efficiency, voltage and current requirements in pure solutions was investigated and is illustrated by curves. The harmful effect of Co is less pronounced with higher current densities. While formerly 320–450 amps./m.^{2} was the usual current density, 6000 amps./m.^{2} is desirable at 60–80° C., especially when Co is present. The lowering of current efficiency when colloids are used to obtain smoother deposits is less at higher temperatures. CEM(7b)

METALLIC COATINGS OTHER THAN ELECTROPLATING (8)

Applying Aluminum in Petroleum Refinery. STANLEY GILL (Gulf Pipe Line Co.). *Chemical & Metallurgical Engineering*, Vol. 37, Aug. 1930, page 483.

Based on paper read before the American Petroleum Institute, Dec. 5, 1929. Al and its alloys are very resistant to H_2S corrosion at temperatures below 250° F. Since the development of numerous fields producing high S crudes, use of Al in the refinery has increased greatly. Solid Al roofs for tanks designed like the usual steel roof are too costly. Light-gage Al has proved valuable as a sheathing over wooden decks of tanks. In some cases where corrosion is extremely severe, it is possible that the cost of solid Al decks will be justified by the savings. Main applications of Al and its alloys will be confined to small pieces of equipment which are not subjected to extremely high temperatures or pressures, but which are rapidly corroded. MS(8)

Aluminum Foil Coatings Cut Evaporation Losses. STANLEY GILL (Gulf Pipe Line Co.). *Chemical & Metallurgical Engineering*, Vol. 37, Aug. 1930, pages 508–509.

From paper read before the American Petroleum Institute, Dec. 1929. Progress report of investigation, still incomplete, on use of Al foil as a coating material for oil tanks. Most difficult feature is the discovery of a suitable adhesive, few having been found. Foil 0.0015–0.005 in. thick has been used successfully. If it is less than 0.003 in. it is likely to be too light. It is very easily applied, if a suitable adhesive has been selected. Foil coatings applied with adhesives that were not oilproof showed a life against severe sulphide corrosion more than twice that of the best paint coatings. Exterior coatings are more resistant to corrosion and afford much better protection against evaporation losses than Al paint. A tank with only the deck foil coated has about half the evaporation rate of a tank entirely coated with Al paint. MS(8)

Large Galvanizing Bath Made of Three Heavy Plates, Welded Together. *Iron Age*, Vol. 126, July 24, 1930, pages 229, 248.

A tank believed to be largest ever produced, was made by Thompson Brothers at Bradley Engineering Works, Bilston, England. Plates are of $1^1/_2$ in. gage for bottom plate and 2 in. for the 2 verticals, each of which made a side and an end. Internal length of bath is 36 ft., width inside 3 ft. 3 in. and depth of 5 ft. 6 in. Weight of each side of plate is 8 tons. Weight of completed tank is 24 tons empty. Its capacity is 130 tons of spelter. Joint welded by the Smith Fire process. Composition of bath material is given. Compares American steel for same purpose. VSP(8)

Deposition of Cadmium on Small Iron and Steel Articles by Immersion. CHARLES H. PROCTOR. *Metal Cleaning & Finishing*, Vol. 2, June 1930, pages 491–493.

Articles must be just as clean as they should be for electroplating. An ideal surface is one that has been sand-blasted, immersed in an acid dip immediately thereafter, and washed in cold H_2O. Fabricated steel articles should be cleaned with a solution of 3 oz. KOH and 3 oz. Na_3PO_4 per gallon, H_2O at 180–200° F., washed, given an acid dip, washed, and given an alkaline dip. The articles are then immersed in the Cd solution consisting of 1 gal. H_2O, 8 oz. KOH, 3 oz. CdO, 2 oz. Na_2SnO_3, 4 oz. $Al_2(SO_4)_3$ (commercial) and $^1/_{10}$ oz. 1 min. Postum. The solution is heated to the boiling point and maintained at this temperature in a wooden or enameled steel tank. A minimum of 30 minutes immersion is required to obtain a Cd deposit that will meet an exposed weather test or a 20 hr. salt-spray test. Malleable iron articles immersed 45 min. in the boiling solution and exposed to a weather test in New York did not show any indication of rusting until the end of 60 days. To increase the life of the rust-resisting qualities of the coating the articles should be immersed for a moment in a solution of pt. China wood oil and 3 pts. CCl_4 and C_2HCl_3, measured by volume. MS(8)

Temperature of Galvanizing Bath Affects Dross Production. WALLACE G. IMHOFF. *Iron Trade Review*, Vol. 86, June 19, 1930, pages 65–66.

Important practical features affecting the character of the dross made are: the size and shape of the galvanizing pot, method of heating the pot, heat distribution, temperature of metal bath, method of drossing the pot, and the drossing equipment. High degree of heat in the bottom of kettle makes dross denser, and causes pot to fail somewhere at dross line. Average normal operating temperature for large amount of material is 850° F. Holes in drossing spoon should be of the proper size. The higher the temperature of the bath, the greater is the dross production, the higher is the Fe content in the dross, and the greater is the specific gravity of the dross. Includes photomicrographs of dross with various percentages of Fe. MS(8)

Bend Tests on Hot-Dipped Zinc Coatings Measured with Micrometer Calipers. WALLACE G. IMHOFF. *American Metal Market*, Vol. 37, Dec. 24, 1930, pages 5, 9, 10.

The complete results of tests on galvanized iron pails are tabulated and lead to the conclusion that the lighter the Zn coating and the lower the temperature of the bath, the better the adherence to the base metal, the less peeling and flaking, and the more ductile the coating. For procuring the best coating, a good grade of zinc must be used, and the proportion of alloys added to the bath is kept at a minimum. The time "through the flux" and the "submersion time" give a combined time of 24 seconds in the metal. Best results (pails from plant Z) were due to: (1) an open steel base; (2) proper picking conditions; (3) good condition of the Zn pot; (4) proper fluxing conditions; (5) the right use of metal additions to the bath; (6) the right bath temperature; (7) the proper submersion time; (8) the proper withdrawal time; (9) the right production for the conditions set; and (10) the lightest weight of metal deposited. A similar number of reasons for the poor deposits (pails from plant S) are given. Thirteen general conclusions are listed and a comparison of the deposits on pails from 4 sources tabulated. WHB(8)

Smoothness of Zinc Coatings. WALLACE G. IMHOFF. *Heat Treating & Forging*, Vol. 16, June 1930, pages 729–731; *Blast Furnace & Steel Plant*, Vol. 18, July 1930, pages 1154–1156.

To obtain a smooth Zn coating, steel should have low P and S, be free of segregation, contain very little oxides and inclusions, have an unoxidized surface, and be poured at the proper temperature. The surface of the steel should be smooth, i. e., contain no rolled-in scale and be free from corrosion and rust. Steel should be properly pickled. After pickling, it should be well fluxed with a hot clean liquid flux which will dry quickly and leave the surface a steel gray color. The flux on the kettle must be kept fresh and glossy, and it should roll onto the work, rather than part. The temperature of the galvanizing bath must be correct. Metal additions must be in the proper amounts. Too much Al and Ag in the bath will make a rough coating. If kettle is not drossed often enough, coating will be very rough. Overheating the bath will also cause a rough coating. Scruf and oxides in the coating are due to wrong temperature and wrong composition of the bath. Too fast withdrawal will give a rough finish. Articles done one at a time have a high quality finish. A number of articles galvanized at one time tend to stick to each other and tear the coating. For smooth coatings, work should be put into the H_2O tank before the coating becomes sticky. The H_2O should be hot for small articles. It can be colder for larger work. MS(8)

INDUSTRIAL USES AND APPLICATIONS (9)

Arc Welding Used for Large Gas Line. *Chemical & Metallurgical Engineering*, Vol. 37, March 1930, page 154.

Uinta Pipe Line Company's arc-welded line from southeast of Rock Springs, Wyo., to Ogden and Salt Lake City, Utah, comprises 200 miles of 18-in. pipe and 77 miles of 16-in. pipe. Each joint in the section is welded twice, 2 separate beads being run around each joint. The first bead is welded with $^3/_{16}$ in. electrodes, about $^3/_4$ lb. of electrode metal being used for the 18-in. joints. The second bead is welded with $^1/_4$ in. electrodes, about $1^3/_4$ lb. being consumed. MS(9)

Heat-Treated Steel Rails. *Iron & Coal Trades Review*, Vol. 121, July 25, 1930, page 126.

Abstract of Report No. 2 at the 11th session of the International Railway Congress Association by M. Cambournac and M. Patte on "Resistance of Rails to Breakage and Wear." Report pertains to all countries except the British Empire, America, Japan, and China. Based on statements from 60 companies who answered the questionnaire sent out by the association. Question No. 6 was: "Have you carried out tests with heat-treated rails? What results have you obtained? Describe the treatment and give its principal characteristics. Explain the test method which has enabled you to satisfy yourself that the treatment has been done properly. In what position and under what condition do you prefer to use heat treated rails?" Describes treatment by the Sandberg process, Newves-Maisons process, and the Maximalianhütte process. The French Joint Committee on rails draws conclusions in favor of heat treatment. French railways have extended the use of heat treated rails. Gives a method of testing to determine whether heat treatment has been properly done. RHP(9)

Aviation Materials—Reviewed in Broad Symposium. *Iron Age*, Vol. 126, July 3, 1930, pages 19–22.

Conducted by the American Society for Testing Materials at Atlantic City, June 27, 1930. Chairman Knerr read a brief introduction on the scope of the aircraft industry. Metals in aircraft construction were discussed by J. B. Johnson in a paper, "Ferrous Metals used in Airplane Construction." R. L. Templin, F. V. Hartman and E. C. Hartman read a paper, "Structural and Engineering Light Alloys for Aircraft." Papers dealing with aircraft engines were, "Failures of Aircraft Engine Parts and Causes Thereof," by Thomas T. Neill and "Materials of Construction in Aircraft Engines," by R. R. Moore. Abstracts of these papers will be found in *Metals & Alloys*, Vol. 1, Nov. 1930, page 849. Jerome Strauss read a paper on "The Highly Alloyed Steel in Aircraft Construction," which is also abstracted in the November issue of *Metals & Alloys* on page 842. Welding as applied to aircraft construction was taken up in papers by H. L. Whittemore, J. J. Crowe and H. H. Moss on "Procedure Control in Aircraft Welding," and T. Watson Downes on "Metal Joints in Aircraft Construction." These are abstracted in the October, 1930 issues of *Metals & Alloys* on page 801. The concluding paper of the symposium was by Horace C. Knerr on "Heat Treatment of Aircraft Parts." An abstract of this is on page 849 of the November 1930 issue of *Metals & Alloys*. VSP(9)

The Uses of Nickel Brasses. SHERWOOD B. SEELEY. *Metals & Alloys*, Vol. 1, Aug. 1930, pages 657–659.

A discussion of the nickel brasses (nickel silver) whose compositions are 60% Cu, 5.30% Ni and the remainder Zn, also those containing small amounts of Pb. The color of these brasses varies directly according to the amount of Ni present. The 18% Ni is silvery white and the 5% Ni is very light colored brass. It is used for ornamental vases and cups and tableware. In these uses the alloys are readily Ag plated. These articles do not bend as readily as sterling Ag. Low priced watches are made of this alloy since wearing of nickel plate disclosed no yellow brass. Rustless equipment in bathrooms, cafes, boats and automobiles are also made from this material. Nickel brass can be drawn and stamped into trays, dish-holders, milking machine parts, etc. It is drawn into wire for mesh bags. A popular patented slip fastener is manufactured from these alloys. Seamless tubing may also be drawn in all sizes from these alloys. Nickel brasses are made to contain 1% Pb. This alloy does not rust, is easily machined, and may be rolled very hard. They are used for keys and rods in automatic screw machines. The rolling treatment of these alloys is similar to ordinary brasses. They may be spun and extruded. The 60% Cu alloy shows a transformation point called fire-cracking. ESC(9)

How Castings Meet Designers' Needs in Modern Machinery. D. M AVEY. *Machine Design*, Vol. 1, Sept. 1929, pages 26–30.

A description of various phases of application of castings to machine construction from the standpoint of the designer. The physical properties of castings are listed. States the properties of gray cast Fe and their value to the machine designer, malleable cast Fe characteristics, as well as those of steel castings and non-ferrous castings. (9)

Belgian Rails: Conditions of Service and Control of Quality. *Iron & Coal Trades Review*, Vol. 121, July 25, 1930, page 117.

Abstract of a paper of this title presented by Jules Servais at the Liege Congress of Mining and Metallurgy. Increased weight, speed, and traffic require better rails. Rails are made of basic Bessemer steel. Tensile strength 68 to 70 kg./mm.^{2} Average carbon 0.45%, maximum 0.55%. RHP(9)

Steel House Construction. *Iron & Coal Trades Review*, Vol. 121, July 11, 1930, page 48.

Abstract of paper read by Lee H. Miller before the American Iron & Steel Institute. See *Metals & Alloys*, Vol. 1, Nov. 1930, page 849. RHP(9)

Metallurgical Progress and Its Influence in Ship Building. (Metallurgische Fortchritte und ihr Einfluss auf den Schiffbau.) C. COMMENTZ. *Zeitschrift Verein deutscher Ingenieure*, Vol. 74, Nov. 22, 1930, pages 1613–1614.

In ship building and construction of marine engines, improvements have been made in the years since the war which are due to a very great extent to improvements in production and working of metals. The question of material in ship building hinges on 3 points: strength, weight and price. Greater strength, as it is found in recent materials, results in reduced weight but is always more expensive. But in marine shipping increased cost of ships can, to a certain extent, be admitted because the loading capacity is increased by reduced weight and, therefore, the pay load is increased. A better economy, especially in engines, can also be obtained. From these points of view, the author discusses the advantages of using high-grade steels for the body of the ship whereby the differences between passenger liners and freight steamers are taken into consideration. The influence of high-grade steel in engines and boilers and the use of light metals are also considered. These last are not yet commonly applied because of their cost, except in warships, large trans-Atlantic passenger liners and small, fast ships. But there seems no doubt that these materials will, in the future, be used in this field to a much greater extent as the shape (flow lines) is essentially influenced by metallurgical progress. Ha(9)

The New Diesel Aircraft Engine. FAY LEONE FAUROTE. *Iron Age*, Vol. 126, July 17, 1930, pages 148–151, 201–202.

Diesel aircraft engine developed by Packard Motor Co. weighs 2.26 lbs./hp., with a maximum speed of 2000 r.p.m. developing 225 hp. at 1950 r.p.m. Operation of diesel engine. Crankcase weighs 34 lbs. and is made of alloy steel. Combination of fuel pump and nozzle are detachable. Pistons are made of Al alloy and the crankcase is made of one piece Mg alloy casting. Domestic fuel oil is used. VSP(9)

HEAT TREATMENT (10)

Heat Treatment of Aircraft Parts. HORACE C. KNERR. *Proceedings American Society for Testing Materials*, Vol. 30, Pt. 2, 1930, pages 154–170. Discussion appended. See *Metals & Alloys*, Vol. 1, Nov. 1930, page 849. (10)

Heat Treating Aircraft Materials. J. W. URQUHART. *Heat Treating & Forging*, Vol. 16, June 1930, pages 743–746.

Describes English practice. Wire is subjected to a straight-line heat treatment process. Electric resistance heating is slowly displacing gas and oil-fired tubular furnaces. Material used for spar building strip intended for heat treatment is a rolled 40–45 ton steel, containing 3–5% Ni and 0.5–1.5% Cr. Heat treatment raises the tensile strength to 80–90 ton/in.^{2} Vertical heat treating system is used for wing strip steel. Strip is made part of an electric circuit. For thicknesses varying from 0.01–0.02 in., actual voltage used is 5.5–9 volts per ft. length of strip. Steel is heated until temperature is 1472–1562° F., which it attains in 15 sec. Current is allowed to flow for almost a minute, when it is diminished until the temperature is about 1336° F. Heated strip is protected from oxidation by carrying it through the heating and cooling phases in a narrow tube of refractory material, filled with a reducing atmosphere. Strip is quenched by drawing it through a chamber filled with ordinary machining suds. It is then extended upon a tempering bench, provided with means of applying considerable mechanical tension upon it, while the steel is being heated to a maximum of 788° F. This eliminates distortions and tempers the steel at the same time. This process is carried out electrically, using 20–40 volts and 100–350 amperes, depending upon the cross-section and width of the strip. Time taken is less than 2 min. MS(10)

Heat Treatment of Cylinder and Alloy Irons. F. J. WALLS & A. HARTWELL, JR. *Fuels & Furnaces*, Vol. 8, July 1930, pages 969–971.

From a paper read before the American Foundrymen's Association. MS(10)

Character of Furnace Equipment Used in Heat Treatment of Aircraft Parts. HORACE C. KNERR. *Fuels & Furnaces*, Vol. 8, Aug. 1930, pages 1103–1105.

From a paper read before the American Society for Testing Materials. See *Metals & Alloys*, Vol. 1, Nov. 1930, page 849. MS(10)

Heat Treatment of Automotive Parts. ERNEST F. DAVIS (Warner Gear Co.). *Fuels & Furnaces*, Vol. 8, May 1930, pages 617–622; June 1930, pages 791–794.

Describes furnaces used and practice followed in annealing, cyaniding, carburizing, and hardening of various automotive parts. MS(10)

Heat Treating in a Modern Forge Shop. M. J. GORMAN (Moore Drop Forging Co.). *Heat Treating & Forging*, Vol. 16, Jan. 1930, pages 41–42.

Usual practice is to normalize, reheat, and quench in oil, water, or caustic solution. Forgings are drawn at 900–1350° F., depending upon physical properties desired. Tabulates properties of SAE 3130 steel after various treatments. Dies to be hardened are placed face down in a furnace having a temperature of 600–800° F., and heated slowly to 1400–1475° F., if made of straight C steel, or to 1450–1550° F., if of alloy steel. The former are water quenched, while the latter are oil quenched. MS(10)

Correct Design and Heat Treatment of Steel Dies for Die Castings. R. L. JOHNSON (Garwood Works, United States Aluminum Co.). *Iron Age*, Vol. 12, Aug. 28, 1930, pages 546–548, 576.

Based on address before joint meeting of the Canton and Cleveland chapters of the American Society for Steel Treating. Proper design of dies can only be attained by experience, designing skill and the application of specialized knowledge. Die casting die steels fail owing to surface checking. Checks are due to fatigue of surface layer in contact with molten metal. Preliminary checking may be due to presence of inclusions in the steel. Die cannot be kept at uniform temperature throughout its mass. Actual life of a die depends on the shape, design and function of the casting. Complicated dies seem to give the best service. Hardening of dies is difficult. One piece dies are more satisfactory. Modern trend is toward use of higher alloy die steels for Al. Dies for Zn-base die castings are made of machine grade of steel, with added chromium. Proper soaking period is important. Furnaces for proper heat treating should be of such type that all parts of furnace are at the same temperature at all times. VSP(10)

Continuous Equipment for Heat-Treating Steel Castings. A. C. JONES (Lebanon Steel Foundry). *Fuels & Furnaces*, Vol. 8, April 1930, pages 475–478.

Two continuous, oil-fired, pusher type furnaces are used. The castings are heated to 1650° F., quenched in air, and drawn at 1225° F. After this treatment, medium C steel has a pearlitic structure. Typical physical properties obtained with different heat treatments of steel with 0.25% C are:

	Yield-point lbs./in.^{2}	Tensile strength lbs./in.^{2}	% elongation	% reduction of area
Annealed	39,500	69,500	28.2	36.2
Normalized	44,500	75,585	27.3	38.0
Normalized and Drawn	42,415	70,417	30.0	46.8

MS(10)

Trend in Heat Treatment of Alloy Steel Castings. A. W. LORENZ (Bucyrus-Erie Co.). *Iron Age*, Vol. 126, Sept. 11, 1930, pages 693–695, 755–756.

Manufacture and treatment of alloy castings is one of the most important developments in the steel founding industry. During past 2 years there was a rapid increase in the use of full-quenching treatments. Car-bottom annealing furnaces are still preferred. Three classes of alloy steel castings have been developed—pearlitic, manganese, nickel chromium and air-hardening chromium-nickel molybdenum. VSP(10)

Hardening (10a)

Tool Hardening Today. A. H. D'ARCAMBAL (Pratt and Whitney Co.). *American Machinist*, Vol. 73, Sept. 18, 1930, pages 472–475.

Over 90% of tool steel made in this country is made by the electric furnace process. It is better quality than that made by the crucible process due largely to closer control. Lists and gives composition of 5 of the more common steels used for tools. Largely a description of methods of treatment used by the Pratt and Whitney Co. RHP(10a)

The Mechanism of Hardening Steel. (Ueber den Mechanismus der Stahlhärtung.) G. KURDYUMOV & G. SACHS. *Zeitschrift für Physik*, Vol. 64, Aug. 28, 1930, pages 325–343.

Austenite (γ-iron) chilled from 1100° to room temperature is partially converted into a tetragonal modification, as shown by X-ray diagrams (Debye-Scherrer) from a rotating rod of the material. The dark ground of the films points to considerable irregularities in the arrangement of the atoms of the crystal lattice. Tempering leads to formation of martensite. The lattice distortion diminishes with increasing temperature and time of tempering. The relative orientation of the crystals of the austenite modification, the tetragonal phase and the γ-iron has been found and the possible course of the rearrangement is discussed. (10a)

Case Hardening & Nitrogen Hardening (10c)

Thermal Analysis of Quenched Carbon Steels. SEIKICHI SATO. *Fuels & Furnaces*, Vol. 8, Aug. 1930, pages 1095–1096.

From a paper published in Science Reports of the Tohoku Imperial University. See *Metals & Alloys*, Vol. 1, Oct. 1930, page 800. MS(10c)

Relation of Time and Temperature to Depth of Case in Carburizing of Carbon Steels. J. SORENSON. *Fuels & Furnaces*, Vol. 8, Jan. 1930, pages 41–43.

Proposes the use of the equation $A = K \times b$ for determining the depth of case obtained in 1 hr. of carburizing time at a definite temperature for straight C steels. A = hrs., K = a constant which varies with carburizing temperatures. The constants for various temperatures are: 1600° F. 0.0045; 1650° 0.0060; 1700° 0.0080; 1750° 0.0110; 1800° 0.0130; 1850° 0.0155. The equation may be used for determining the time required to obtain a desired depth at a definite temperature. The constants are merely to be used as a guide in determining the depth that can be obtained under average conditions. Although based on results obtained from actual experience, various factors may cause variations. MS(10c)

Case Hardening with Nitrogen. C. F. OLMSTEAD (Mahr Mfg. Co.). *Heat Treating & Forging*, Vol. 16, April 1930, pages 509–511.

Includes bibliography of 9 references. General, non-technical review of the nitriding process, advantages of nitriding, and the steels suitable for nitriding. MS(10c)

The Case-Hardening of Commercial Steels by Means of Nitrogen. B. JONES. *Iron & Steel Industry*, Vol. 3, Dec. 4, 1930, page 77.

The specimens (3/4" square) were nitrided 90 hours in silica tube 3' length of 3 1/2" diameter. The steels studied included 5 austenitic and 20 plain C and alloy steels. The austenitic steels were of the following types: 18–8 Cr-Ni, invar., 15–5 Ni-Mn, 26.5–13.4–3.5 Ni-Cr-W, and 1.25–13.2 C-Mn. The C contents of the plain C steels were 0.04, 0.30, 0.60, and 0.90%. The alloy steels included 4 and 5% Ni, two Ni-Cr, Ni-Cr-Mo, 2 Cr-Al-Mo, 2 Ni-V, Ni-Cr-V, 2 Cr-V, 2, 13, and 29% Cr and a 2% Al. Dry NH_3 gave greater hardness and better appearing cases. Nitriding temperatures of 600 and 650 showed a tendency to embrittle the case. Austenitic steels, in which the austenite was stable at the nitriding temperature, were not appreciably hardened. The 1.25–13.2 C-Mn transformed and showed increased hardness due to the transformation and to some nitriding. The plain C steels show the following % increase in hardness: 82, 88, 44, and 8 for 0.03, 0.30, 0.60, and 0.90% C, respectively. Of the alloy steels the Cr-Al-Mo steels showed the best results. Next in order came stainless steel, 1.2 Cr-0.7 V, 1.2 Cr-0.4V, and 2.0 Al. The 4 and 5% Ni steels showed no hardening. The author studied the duplex treatment of calorizing and nitriding. Calorizing before nitriding improved the nitriding properties of the steels in the following decreasing order: 4 Ni, 2.7 Ni-0.4 V, 5 Ni, 0.60 C, 0.30 C. Calorizing was harmful to Cr-Al-Mo, invar and Ni-Cr-W steels. The bibliography contains 25 references, very few American. OEH(10c)

Nitriding of Steel in European Practice. J. W. URQUHART. *Heat Treating & Forging*, Vol. 16, Jan. 1930, pages 48–50, 52.

Nitralloy concerns recommend that steels for nitriding contain from 0.9–1.3% Al. Normal depth of the case is 0.02 in. which is generally obtained by heating at about 500° C. for 90–100 hrs. All other treatments should be completed, and the surfaces should be thoroughly cleaned before nitriding. Boxes of 18% Cr-Ni steel are used in British practice. The ordinary nichrome ribbon resistor furnace is used in all European countries. Wire basketing is often used to hold the work. Flow of NH_3 is regulated to give a dissociation of 25–30%. Hardness of case is comparable to that of bort. MS(10c)

Quenching (10d)

Selection of Heat-Treating Oils. ARTHUR MUMPER. *Heat Treating & Forging*, Vol. 16, April 1930, pages 460–461.

Proper quenching oil for oil-hardening non-shrinkable steels is determined by the nature of the pieces to be treated. Consideration should be given to the difference in specific gravity of oils. Light oils conduct heat more rapidly than heavy oils. Therefore, the former are more suitable for heavy sections of steel, while the latter are better for thin sections. Illustrates the point by describing the quenching of a high Mn steel die ring and a W steel die plate, both of which were quenched at 1500° F. and drawn at 385° F. MS(10d)

Single Quenching after Carburizing. WILLIAM F. CHUBB. *Heat Treating & Forging*, Vol. 16, April 1930, pages 481–483.

Reprinted from *Metallurgia*, Vol. 1, March 1930, pages 197–199. MS(10d)

Aging (10f)

The Age-Hardening Process in Alloys (Separation of Supersaturated β Copper-Zinc Solid Solution on Aging at Different Temperatures). (Zur Kenntnis des Vergütungsvorganges in Legierungen. (Der Vorgang der Entmischung übersättigter β(Cu-Zn)-Mischkristalle durch Alterung bei verschiedenen Temperaturen.)) M. HANSEN. *Mitteilungen der deutschen Materialprüfungsanstalten*, Sonderheft 13, 1930, pages 25–37; also in *Zeitschrift für Physik*, Vol. 59, 1930, pages 466–496.

A phenomenon quite similar to that met in duralumin occurs in the β brasses of around 60 1/2 to 57 1/2% Cu. The β field is separated from the $\alpha + \beta$ field by a sloping line. Alloys quenched from above this line retain the β structure, but on aging at elevated temperatures, the transformation to $\alpha + \beta'$ occurs, since β' is the stable form below 453° C. The effect of quenching temperatures and aging temperatures was studied on 6 alloys in this range of compositions, and the effect of quenching rate (into water at 0°, 20° and 100° C.) was studied on a 59% Cu alloy. The necessary quenching temperature, of course, varies with the composition. The obtainable hardness rises as the composition, within the range of composition studied, approaches the high-copper side. Alloys of 60 to 60 1/2% Cu with about 115 Brinell as quenched, gave hardnesses of over 200 Brinell on aging at 150° C. for 8 days, 175° C. for 4 days or 200° C. for 18 hours. At 250° C. it reached 20 Brinell in less than an hour, but in 100 hours, it fell almost to the original value. At 300°, the hardness rose only to 160 Brinell after 10 minutes heating, and was reduced almost to the original value in 8 hours. Heating at 175° for 20 days showed no softening from the maximum hardness obtained in 4 days. Quenching into water at 0° or 20° made little difference, but quenching into boiling water was nowhere near so effective. The separation of β was followed by observing the change in electrical resistance which was rather similar to the change in hardness. There was no change in resistance or hardness that could be connected with the β to β' inversion, the behavior being as if β only were concerned. At aging temperatures of 250° C. and below, the increase in resistance appears to take place in 2 steps. A large increase in resistance is first shown, without a corresponding increase in hardness, after which the resistance falls while the hardness rises. The first change is ascribed to lattice distortion and internal stress; the second to separation of β. HWG(10f)

JOINING OF METALS & ALLOYS (11)

Brazing (11a)

Electric Resistance Brazing. W. C. Reed (General Electric Co.). *American Machinist*, Vol. 73, Nov. 13, 1930, pages 779–781.

Describes resistance brazing equipment. Silver alloys are used as the brazing media. Joints may be brazed by this process in less time than by soldering and the results are greater strength, greater electrical conductivity, and smaller joint. RHP(11a)

Soldering (11b)

A New Solder for Electrical Apparatus. James Silberstein. *Metals & Alloys*, Vol. 1, Aug. 1930, pages 659–660.

Since the eutectic arrest at 182.5° C. in the system Pb–Sn reaches from pure Sn to 85% Pb, any Pb–Sn solder will fail at this temperature. Good soldering requires cleanliness of surfaces. A lead chloride flux permits a very tenacious adherence between Al and Pb although Pb and Al will not form an alloy. Observation of failure temperature of 5 soldered joints tabulated:

Alloy Comp.	45% Sn, 58% Pb	100% Sn	3.5% Sn, 96.5% Pb	2.5% Ag, 0.25% Cu, 97.25 Pb	100% Pb
Temp. of Failure	175°–179° C.	210°–214° C.	230°–239° C.	296°–301°C.	314°–317°C.

Temperature failure tests of various solders simultaneously observed indicate that pure Sn and $^{42}/_{58}$ Pb–Sn solders fail at the same current. In both cases the Ag–Cu–Pb alloy was superior. ESC(11b)

Soldering Aluminum. (Das Löten von Aluminium.) L. Rostosky & E. Lüder. *Apparatebau*, Vol. 42, Feb. 21, 1930, pages 37–42.

A discussion of the properties of the joints and their structure when welding or soldering Al. (11b)

Solders and Soldering Fluxes. A. Eyles. *Sheet Metal Worker*, Vol. 21, Oct. 3, 1930, pages 600, 608; Oct. 31, 1930, pages 668, 672; Nov. 14, 1930, pages 688, 706.

Fabrication, composition and use of various solders and fluxes, British research of solders and metallurgy of soldered joints. GN(11b)

Welding & Cutting (11c)

Influence of Flux Coated or Covered on the Metal Arc Electrode. M. Haramiishi (Tokyo Salvage Company, Ltd.). *Journal American Welding Society*, Vol. 9, June 1930, pages 33–46.

During metallic arc welding not only is there a physical change in metal structure taking place in the electrode caused by the heat of the arc but there is also chemical change. After much study of this intricate subject it was found that: (1) Any desired metal can be obtained chemically in the deposited metal with the flux coated electrode, although wire core has some elements which are main components of the desired alloy metal, the flux has the other required elements; (2) by utilization of heat given off by the arc, the deposited metal can be chemically changed from that of wire core with the prepared flux; (3) chemical change occurs in the electrode as well as in the flux when the heat of the arc is applied; (4) flux works as a medium in supplying necessary elements for the desired alloy adjusting the heat temperature of the molten metal suitably and protects it against undesirable impurities. Tests were made with cast-iron, high-speed steel, high-Mn steel, hypo-eutectic steels, and gun-metal. Includes numerous photomicrographs. LFM(11c)

Copper Welding in the Chemical Industry. S. J. Mashl (Van Schaak Bros. Chemical Works). *Journal American Welding Society*, Vol. 9, June 1930, pages 46–53.

Tough pitch Cu is most suitable type of Cu for welding. Due to its affinity for O, deoxidizing agents such as P, boron suboxide, Al, and Si are used. Rod used must contain substance that will dissolve oxide or prevent its formation. Rod should have same melting point as article to be welded. Best results are obtained when rod is applied at same time that parent metal becomes molten. Recommends annealing weld after it has cooled. Describes welding procedure as carried out in the plant giving photographs showing applications of various types of welds. LFM(11c)

Welding of Super Code Pressure Vessels. L. H. Burkhart (Struthers-Wells-Titusville Corp.). *Journal American Welding Society*, Vol. 9, June 1930, pages 28–32.

Gives results of tests carried out on welded specimens. In tensile tests no specimen broke in or near the weld showing that weld is stronger than the plate. Ductility tests were made by bending in a hydraulic press. Elongation ranged from 16 to 20%. Special tests were made on specimens of all weld or deposited metal which showed why no specimen broke in the weld. Tensile strength of weld metal is 50% greater than that of plate used and elongation 20% greater and reduction of area 30% greater. Gives tables and photographs. LFM(11c)

Welding as Performed at Present. J. W. Urquhart. *Heat Treating & Forging*, Vol. 16, May 1930, pages 595–597, 602.

Considers and compares the different methods of electric welding used in Europe. A point brought out is that certain kinds of rods work best when the current supplied to them is from the negative pole instead of the positive, the latter being earthed. Author's experiments indicate that the composition of the steel being welded has more influence than that of the rod in determining the polarity of the rod. MS(11c)

Welding Aluminum Castings. *Foundry*, Vol. 58, June 15, 1930, page 55.

Prior to welding the piece is usually preheated, temperature being raised slowly to proper heat. Illustrates and describes method of procedure on a lid of a rotary bottling machine 56 in. in diameter and $^3/_4$ in. thick. VSP(11c)

New Developments in Tube Welding. Ferdinand Owesney, Jr. *Blast Furnace & Steel Plant*, Vol. 18, April 1930, pages 620–621.

From *Die Rohrenindustrie*, Vol. 23, Oct. 23, 1930, pages 339–340. Discusses application of medium and high frequency induction welding. Machine in which the principles are applied will be placed on the market in the near future. MS(11c)

Cutting Up Heavy Scrap with Oxygen Lance. *Blast Furnace & Steel Plant*, Vol. 18, April 1930, pages 644–645.

From *Oxy-Acetylene Tips*. MS(11c)

Acetylene-Electric Welding. (Azetylen-elektrisches Schweissen.) Adrian. *Zeitschrift Verein deutscher Ingenieure*, Vol. 74, Nov. 15, 1930, page 1584.

The author describes a new method of welding with acetylene and electric arc combined as it has been developed by IG-Farbenindustrie and AEG. The advantage of protection against the air of the acetylene flame and local heating and purity of heat source of the electric arc are combined in this way. The electrode of the electric circuit is introduced into the acetylene flame which proceeds in the direction of welding and pre-heats the edges. Alternating current is used; the amperage is lower, the voltage somewhat higher (about 33 volts). The welding speed is greater than in acetylene welding, about double for a plate of 6 mm.; the costs are about 30% lower. The quality of the joint is good but the human factor has a considerable influence, as this method cannot as yet be made automatic. Ha(11c)

Stress Distribution in Side-Welded Joints. W. H. Weiskopf & Milton Male. *Journal American Welding Society*, Vol. 9, Sept. 1930, pages 23–48.

Presents 3 new features in connection with side-welded joints; that is, joints in which the welds are disposed parallel to the direction of stress: (1) A theory as to the manner in which welds deform under shearing loads and, resulting therefrom, a determination of the value of the Detrusion Ratio, D. (2) A means of determining the effective areas of the bars composing such a joint (the percentage of the total areas that should be considered as transmitting load). (3) A method of determining the length of the welds, such that the maximum shear stress will not exceed the average design stress by more than any desired ratio. These are offered not with idea that problem is completely solved, but as practical suggestions that may be used with safety pending further investigation. In the 1930 test it was impossible to reconcile theory presented with only one short weld specimen tested so no definite conclusions could be drawn. Highly theoretical discussion is given with many graphs, diagrams, and formulae. Summary of results of thesis presented at Univ. of Pittsburgh by Haven, Logan and Hobe. LFM(11c)

Principles of Steel Mill Practice Applied to Welding. J. B. Austin (Una Welding & Bonding Co.). *Rolling Mill Journal*, Vol. 4, June 1930, pages 319–322.

Abstract of a paper read before the Association of Iron & Steel Electrical Engineers, June 16–20, 1930. See *Metals & Alloys*, Vol. 1, Oct. 1930, page 801. MS(11c)

Investigations into the Influence of Covered Welding Electrodes on the Mechanical Properties of the Welds. (Untersuchungen über den Einfluss von Umwicklungen der Schweisstäbe auf die mechanischen Festigkeitseigenschaften der Schweisse.) K. Baumgaertel. *Forschungsarbeiten auf dem Gebiete des Ingenieurwesens*, published by the Verein deutscher Ingenieure, No. 336, 1930, 33 pages.

It has been found that the absorption of oxygen and nitrogen from the surrounding air during welding reduces the mechanical properties of the weld; to exclude or to reduce this influence the welding rods are provided with a kind of covering or are dipped. In order to obtain a clear view on this question tests were made with the following kinds of welding rods: (1) bare rods; (2) dipped rods of the American Welding Process Co. (*a*) intermediate, (*b*) normal; (3) asbestos covered rods of the same company, (*c*) special A, (*d*) special B, (*e*) low volt, (*f*) standard. The rod itself had the following composition in all cases: 0.11 C, 0.01 Si, 0.41 Mn, 0.023 P, 0.037 S, remainder Fe. In the covered rod, asbestos takes the place of a flux. The chemical composition of the coating is given in detail for every kind of rod used and contains especially calcium- and aluminum-silicates. The test results showed that the 2 light coverings *a* and *b* do not materially influence the tensile properties and simply facilitate welding. The asbestos covered rods, however, covered with a flux show a decided favorable influence as illustrated by physical, chemical, metallographic, and X-ray tests. Of course, the proper chemical composition of coating is necessary, correct manipulation of the rod, and proper care in welding. The least influence was found in the Brinell test, while tensile strength and elongation showed considerable improvement compared with bare electrodes; the same was true also for bending tests, some of the samples could be bent 180° without fracture. X-ray tests showed finer-grained structure for covered electrodes. Ha(11c)

Gas Welding Machines in Germany. K. P. Berthold. *Welding*, Vol. 1, Oct. 1930, pages 815–819.

Begins with an enumeration of the various applications of welding in Germany, which are practically the same as in the U. S. Germany is gradually overtaking the great lead the U. S. has enjoyed in this field. Gas welding is still preferred in Germany to electric seam welding, opinion being that a seam subjected to heavy stresses should preferably be gas welded, for such a seam is always tougher and stronger than an electrically welded one. This conservative attitude is strengthened by the consideration of the cost of installing an electric welding set. The Mauser seam welding machine, a machine for welding heavy containers, and circular seam welding machines for special purposes are described. Concludes with a survey of the basic factors determining the economical use of automatic welding. As a rule, welding machines are applicable only in case of mass production. W(11c)

Shrinking Stresses and their Consideration in Arc-Welding. (Schrumpfspannungen und ihre Beachtung beim Lichtbogensschweissen.) Bondy. *Zeitschrift Verein deutscher Ingenieure*, Vol. 74, Nov. 15, 1930, page 1560.

It is suggested that the initial interior stresses in structural material which are opposed to those actually existing later in service be produced by welding; this might lead to a reduction in weight. Lottmann, in a reply, believes that before practical use it should be ascertained whether these initial interior stresses remain constant or if they will disappear in time. Ha(11c)

Safe Welding of Empty Barrels for Mineral Oils. (Gefahrloses Schweissen von Entleerten Mineralölfässern.) Brauer. *Schmelzschweissung*, Vol. 9, Dec. 1930, pages 272–274.

Very often accidents are caused due to welding or soldering done on empty barrels which had been filled with mineral oils. A mixture of benzine vapor and air is explosive at a ratio of 2.5 to 4.0% vapor in 100 parts of the mixture, that is, in a barrel of 200 l. contents 10 to 25 g. of benzine are required; the explosion is the most violent for 17 to 20 g. Such residues of oil can be held by films of corroded material on the inside. The author discusses and describes several methods of eliminating the formation of vapors of which the best seems to be rinsing with water before welding until no trace of oil can be discovered on the surface of the water. It is absolutely necessary to instruct the personnel thoroughly as to the danger of work on empty oil barrels and tanks. Ha(11c)

A Year of Arc Welding. A. M. Candy. *Welding*, Vol. 1, Jan. 1930, pages 159–161.

Reviews commercial activities in the general arc welding business for 1929, which was greater than in any other 12-month period. A curve illustrates increase in this business by quarterly periods since Jan. 1927. W(16)

Destruction Test of an Electrically Welded Superheater Drum. O. L. Cox. *Mechanical Engineering*, Vol. 52, Dec. 1930, pages 1063–1064.

Description of procedure of test and results. GN(11c)

Welding Practice in the C. B. & Q. Railway Shops. Joseph C. Coyle. *Welding*, Vol. 1, Oct. 1930, pages 820–823.

Welding is especially applicable for use in railroad shops because of the saving that can be effected by repairing and reclaiming various equipment, such as cross heads, smoke stacks, frames, wheels, cylinders, drawing boxes, front end plates, flues, both the arc and oxy-acetylene processes being used. For example, worn cross heads, costing $75.00 or more new, are reclaimed by arc welding for about $5.00 each; cast iron smoke stacks, costing $40.00 new, are reclaimed with acetylene torch for about $9.00. A description of the equipment, procedure and some of the structures reclaimed is given. W(11c)

Much Arc Welding in New Liquid CO_2 Plant. A. F. Davis (Lincoln Electric Co.). *Chemical & Metallurgical Engineering*, Vol. 37, July 1930, page 435.

Much of the stacks, piping, absorbing towers, and tanks in the plant of the Liquid Carbonic Corporation at Cleveland, Ohio, is fabricated by arc welding. MS(11c)

WORKING OF METALS & ALLOYS (12)

Melting and Refining (12a)

High-Quality Basic Open-Hearth Steel. *Iron & Coal Trades Review*, Vol. 121, Aug. 22, 1930, page 262.

Abstract of Technical publication, No. 347 of the American Institute of Mining and Metallurgical Engineers on "Practical Observations on Manufacture of Basic Open-Hearth, High-Carbon Killed Steel," by W. J. Reagan See *Metals & Alloys*, Vol. 1, Nov. 1930, page 852. RHP(12a)

Making Wrought Iron Mechanically in 700 lb. Balls. *Iron Age*, Vol. 125, June 19, 1930, pages 1814–1817.

Describes method employed by the Wrought Iron Co. of America, Lebanon, Pa. Time in puddling operation is saved by melting pig Fe in oil-fired furnace, whence it is taken in 700 lb. installments and poured into rotary furnace. Operations in rotary furnace are similar to those involved in hand-puddling, except that melting takes place elsewhere. Operation is either by oscillation or rotation. Each heat requires about 45 minutes. VSP(12a)

The Analysis of Basic Slags and the Representation of Their composition in a Triangular Diagram. OTAKAR QUADRAT. *Engineer*, Vol. 150, Oct. 3, 1930, page 360.

An abstract of a paper read before the Iron and Steel Institute, Prague, Sept. 16, 1930. See *Metals & Alloys*, Vol. 1, Dec. 1930, page 915. LFM(12a)

Open-Hearth Trends During 1929. L. F. REINARTZ (American Rolling Mill Co.). *Blast Furnace & Steel Plant*, Vol. 18, Jan. 1930, pages 96–99.

Progress in furnace construction is toward larger capacities. Construction of roofs, ports, valves, dampers and checkers is being improved. Fuel is being conserved by means of insulation and better furnace control. European steel men do not favor the very large stationary furnace. Research in steel-making processes is aiding the open-hearth operator. MS(12a)

Basic Open-Hearth High Carbon Killed Steel. W. J. REAGAN (Edgewater Steel Co.). *Blast Furnace & Steel Plant*, Vol. 18, Sept. 1930, pages 1473–1475, 1481; Oct. 1930, pages 1611–1612, 1618.

Paper read before the Iron & Steel Division of the American Institute of Mining & Metallurgical Engineers. See *Metals & Alloys*, Vol. 1, Nov. 1930, page 852. MS(12a)

Calcium Molybdate, Iron and Steel Making. THOMAS W. HARDY (Mines Branch, Department of Mines, Canada). *Blast Furnace & Steel Plant*, Vol. 18, April 1930, pages 613–617; May 1930, pages 784–788, 795; *Heat Treating & Forging*, Vol. 16, April 1930, pages 471–474, 480; May 1930, pages 608–613.

Outlines the history and occurrence of Mo, its effect on the properties of steel, its early applications to ferrous metallurgy, the use of the ferro-alloy as an addition agent and particularly the development of $CaMoO_4$ as an alloying agent. Experimental heats using the compound as an addition were made in 1918, and a U. S. patent was granted to Alan Kissock on April 15, 1919. However, it was not until 1925 that the process became generally used. Discusses characteristics of $CaMoO_4$. In the basic electric furnace, it is the slag which accomplishes the reduction of the salt whereas, in the open-hearth furnace, it is probable that the Fe is mainly responsible. Recovery of Mo from $CaMoO_4$ is as high as that from the ferro-alloy. $CaMoO_4$ cannot be used satisfactorily to introduce more than $1^1/_2$% Mo. As a general rule in steelmaking, the molybdate should be added before or during the period in which a heat is being "worked down." The most generally used methods of applying it in the basic open-hearth process are (1) to add it after the lime begins to "come up" and before slag is formed and (2) to add it after the slag has formed but at least 2 hrs. before tapping. Method (2) is generally used in the acid open-hearth process. Usual practice in the basic electric process is to add it either on the bare metal just after skimming off the slag, or immediately after the CaO has been thrown in. Best practice in the acid electric process is to charge it with the scrap. In converter practice, the requisite number of bags are thrown into the vessel and the hot metal poured on top of them. In the crucible process, if the Mo content in the steel does not exceed 0.30%, the molybdate is placed in the middle of the charge in the crucible. For higher percentages, it is unsatisfactory. It cannot be successfully added in the ladle. Best practice in the air furnace is to distribute the requisite number of bags throughout the charge. Use of $CaMoO_4$ in the cupola is not recommended unless the cupola is producing nothing but Mo iron. It is charged on each layer of coke in sufficient amount to introduce the desired percentage of Mo into the layer of metals immediately above. It is preferable to use briquetted $CaMoO_4$. Mo pig-iron may be produced by mixing the briquetted molybdate with iron ore and charging into the blast furnaces. This has not been done commercially, however. $CaMoO_4$ is an ideal starting point for the manufacture of ferro-Mo. Mo in small percentages has been successfully alloyed with certain non-ferrous metals by adding the molybdate to the molten metal in the electric furnace. The salt is particularly suited for reduction by Si or alumino-thermic methods. MS(12a)

Steel Castings. C. HOWELL KAIN. *Foundry Trade Journal*, Vol. 41, Dec. 5, 1929, pages 403–404; Dec. 12, 1929, pages 422–425.

The author discusses details of the production of electric steel castings. In experiments on a duplex process, hot cupola metal was charged into an electric furnace and ored down to 0.1% C and the oxidizing slag then removed. The bath was boiling gently at this point. A reducing slag was built up and the heat finished as quickly as possible by Fe-Si and Fe-Mn additions. The steel, when tapped, although not unduly hot had a high degree of fluidity with an absence of wildness. The recovery of Si is increased from 65% of the amount charged when the Fe-Si is added directly after the removal of the oxidizing slag to 135% when the Fe-Si is added only after the reducing slag has been built up. This high yield is explained by the fact that in addition to some Si being reduced from the slag, the Fe-Si is added when the bath is quiet and there is little tendency for the Si or silica to be removed by the boil. Al or Ti can be used for final degasification. The action of Al is instantaneous while Ti gives its best results only when the metal is allowed to stand from 3 to 5 min. before pouring. Molding methods used in the solution of several difficult casting problems are discussed. (12a)

Certain Methods of Deoxidizing Steel. J. M. GAINES, JR. *Blast Furnace & Steel Plant*, Vol. 18, Jan. 1930, pages 102–104.

Present methods of deoxidation result in the formation of non-metallic inclusions in steel. After considering the factors which necessitate deoxidation, proposes a method making use of the rodding reaction. First stage of the process would be the removal of the slag, substituting an inert material such as a lime-clay mixture. In some cases it might prove feasible simply to thicken the existing slag to the point where slag-metal reaction is sufficiently retarded. Second stage would be deoxidation by the introduction of solid objects such as rods, or if C is low, lumps of washed metal or bars of graphite. Tubes through which N is blown into the bath might be used instead of rods. Advantages of the method would be lower inclusion content of the finished product, with consequent reduction in chipping costs, and a saving in the amount of ferro-alloys used. Chief disadvantages appear to be the time and material represented in the exchange of slags. MS(12a)

Casting & Solidification (12b)

Properties of Die Castings Affected by Casting Practice. CHARLES PACK. *Iron Age*, Vol. 126, Nov. 13, 1930, pages 1386–1388.

Taken from a paper read before the Institute of Metals Division of the American Institute of Mining and Metallurgical Engineers at the National Metal Congress. See *Metals & Alloys*, Vol. 1, Nov. 1930, page 852. VSP(12b)

On the Volume Change of Manganese and Some Alloys which Contain Nickel or Cobalt during Solidification. K. HONDA, Y. MATUYAMA & Y. ISOBE. *Kinzoku no Kenkyu*, Dec. 1930, pages 635–639.

The volume change of alloys: nickel-carbon eutectic (2.23% C), cobalt-carbon eutectic (2.20% C), manganese-carbon (1.1% C) and distilled pure manganese has been measured by means of a thermobalance. The authors showed that pure manganese and manganese-carbon alloy which forms a solid solution at high temperature contract during solidification, the former, by 4.5% and the latter, by 1.60%. But the alloy nickel-carbon eutectic expands by 2.06% and the cobalt-carbon eutectic by 2.03%. This expansion is caused by the formation of graphite during solidification; the specific volume of the graphite is very large as compared to that of nickel or cobalt. KT(12b)

Designing for Aluminum Die Castings. D. B. HOBBS. *Product Engineering*, Vol. 1, Feb. 1930, pages 60–62.

The die-casting process consists in forcing molten metal under considerable pressure into steel dies. The main characteristics of die castings, their extreme accuracy, uniformity and superior finish are the result not only of the method by which the castings are made, but also of the fine art developed in die construction. The fact that Al alloys have a higher melting point than Pb, Sn, and Zn alloys required the development of special alloy steel dies. A general description of the casting process is given. (12b)

Ingot Phase in the Manufacture of Rolled Steel Products. Pt. I–VI. JOHN H. HRUSKA. *Rolling Mill Journal*, Vol. 4, Apr. 1930, pages 145–148; June, 1930, pages 309–312, 318; July, 1930, pages 367–370; Aug. 1930, pages 417–418, 430; Sept. 1930, pages 471–473; Dec. 1930, pages 681–682, 687–688.

Deals with the importance of the teeming phase for the production of good rolled products; top and bottom pouring practice; solidification of steel ingots; types of molds and their influence on the soundness of the ingots; formation of dendritic structure; causes of blow-holes in ingots and means for their reduction; location and extent of segregation and teeming practice for its diminution; and inclusions in steel. MS(12b)

Cast Iron or Steel Stools for Ingot Molds. JOHN H. HRUSKA. *Iron Age*, Vol. 126, Oct. 2, 1930, pages 920–921, 974–975.

Most economical method is to make stools and molds from alloy gray Fe or alloy cast steel. Structural changes of stool metal are accompanied by changes in shape or cross-section of stool. Most important feature in stool design is proper consideration of central overheating of stool in filling the mold. Stool should receive the same care and attention in design, maintenance and storage as ingot molds. Includes a table giving composition of metal in stools. VSP(12b)

Centrifugal Castings of Metals. (La coulee centrifuge des metaux.) HENRI CESSELIN. *Revue de Metallurgie*, Vol. 27, June 1930, pages 301–315.

Attention called to the lack of centrifugal casting plants in France. General principles of centrifugal casting in chills are given and their application illustrated by the practice of U. S. Cast Iron Pipe and Foundry Co., Birmingham. Casting in heated molds and casting of billets is given as an abstract of Leon Cammen papers (*Iron Age*, Vol. 110, page 655; *Transactions American Society for Steel Treating*, Vol. 11, page 915, etc.). JDG(12b)

The Heterogeneity of an Ingot Made by the Harmet Process. A. KRIZ. *Engineering*, Vol. 130, Sept. 19, 1930, page 371.

Abstract of discussion of papers read before the Iron & Steel Institute, Sept. 1930. See *Metals & Alloys*, Vol. 1, Dec. 1930, page 915. LFM(12b)

The Heterogeneity of an Ingot Made by the Harmet Process. ANT. KRIZ. *Engineering*, Vol. 130, Oct. 31, 1930, pages 565–567.

Condensed from paper read before the Iron and Steel Institute, Prague, Sept. 15, 1930. *See Metals & Alloys*, Vol. 1, Dec. 1930, page 915. LFM(12b)

Castings for Bronze Gears. FRANCIS W. ROWE (Davis Brown & Sons). *Metallurgia*, Vol. 3, Dec. 1930, pages 50–52.

Cu wire bars and Banks Sn should be used in making the alloys. Correct melting practice is also required. Weak and unsound castings may be due to either poor raw materials or to faulty melting practice. JLG(12b)

The Electric Heating of Ingot Tops in Order to Obtain Dense Ingots. (Die elektrische Blockkopfbeheizung zur Erzielung dichter Stahlblöcke.) EBERHARD LETIXERANT. *Stahl und Eisen*, Vol. 50, Dec. 25, 1930, pages 1801–1805.

Report 185 of the Steel Mill Committee of the Verein deutscher Eisenhüttenleute. Includes discussion. The equipment for the electric heating of steel ingot tops, as supplied by Börnecke & Borchart, Witten, Germany, is described. Practical results of this new method are given, with detailed information as regards the cost. An essential saving of steel can be accomplished because the amount of scrap decreases. The method was tested in 7 different German steel plants on ingots from 15 to 100 tons. GN(12b)

Large Centrifugal Castings Made at Navy Yard. JOSEPH F. CROWELL (U. S. Navy). *Iron Age*, Vol. 126, Oct. 9, 1930, pages 994–996, 1047.

Centrifugal method is highly satisfactory for production of hollow cylindrical castings, which must be non-porous, of uniform texture and hardness, close-grained and free from blow-holes. Molds in large machines are lined with sand. Both horizontal and vertical machines are used at Navy Yard. Casting babbitt metal on inside surface of a bearing brass, the bearing brass forms the insert. Barrel for largest machine is made from 13 in. naval gun. Maximum speed of barrel is over 750 r.p.m. Speed during pouring depends on size of casting and material used. At present no definite information is available regarding % of losses to be expected. VSP(12b)

The Formation of Graphite in Cast Iron. (Die Graphitbildung in Gusseisen.) O. VON KEIL. *Archiv für Eisenhüttenwesen*, Vol. 4, Nov. 1930, pages 245–250; *Stahl und Eisen*, Vol. 50, Dec. 4, 1930, pages 1718–1719.

The investigation attempts to settle the dispute on the formation of graphite in cast Fe as to whether there is the formation of graphite due only to the decomposition of cementite or a direct crystallization of graphite, or both occurrences simultaneously. It was found that the needle-like formation of graphite indicates the direct crystallization in the liquid phase, whereas the finely distributed graphite indicates a metastable crystallization with succeeding decomposition. It was furthermore proven that every cast Fe, dependent on the C content, has a critical cooling velocity which, when underpassed, results in a stable crystallization (needle graphite) but in a fine crystallization of graphite when exceeded. The influence of superheating on the crystallization was studied. In superheating, the critical cooling velocity is shifted to very low values, i. e., superheated cast Fe, even for slow cooling, crystallized metastable with following decomposition. The results confirm investigations by Piwowarsky and Hanemann. GN(12b)

Rolling (12c)

Modern Lubrication in Steel Mills. (Neuzeitliche Schmierung in Eisenhüttenwerken.) E. CHRISTIAN. *Stahl und Eisen*, Vol. 50, Oct. 23, 1930, pages 1501–1502.
The article emphasizes the economics of centralized pressure-lubrication systems in steel plants. Figures are given showing the decrease of power consumption in rolling mills in using pressure lubrication. GN(12c)

New Types of Rolling Mill Guides. (Neuerung an Walzwerksführungen.) O. ROLOFF. *Stahl und Eisen*, Vol. 50, May 1, 1930, pages 602–603.
The author points out the usefulness of alloy steel tips for rolling mill guides in all cases where excessive wear occurs. Guides provided with these tips showed a lifetime 8 to 10 times longer than that of regular cast iron guides. GN(12c)

Continuous Rolling Mills for Materials of High Hot Tensile Strength. (Kontinuierliche Walzenstrasse für Werkstoff mit hoher Warmfestigkeit.) W. ROHN. *Stahl und Eisen*, Vol. 49, Dec. 5, 1929, pages 1757–1760; Dec. 12, 1929, pages 1793–1797.
Some continuous rolling mills for rolling materials of high hot tensile strength are described in detail. These mills are efficient in spite of the low capacity they have in part, not more than 300 tons/yr. The experiences with these mills lead to the belief that this new type of mill can also be successfully used for rolling steel of high hot tensile strength. GN(12c)

Modernization of a Rolling Mill for Strips and Hoops. (Mechanisierung einer Walzenstrasse für Röhrenstreifen und Bandeisen.) B. QUAST. *Stahl und Eisen*, Vol. 50, Feb. 13, 1930, pages 206–207.
The article describes the accomplishment attained by modernizing an old type two-high mill, particularly the following: 80% decrease of wages, lower power consumption, the possibility of rolling products of greater length, a smaller thickness, avoiding of scale due to the sharp bending of the steel in the repeaters and increase of the capacity of the mill. GN(12c)

Lateral Pressure in Box Passes. (Die Notwendigkeit des seitlichen Druckes in geschlossenen Kalibern.) HEINZ PUPPE. *Stahl und Eisen*, Vol. 50, Dec. 11, 1930, page 1750.
The author shows that it is advisable to use alternatively open and box passes in rolling shapes like U's, beams, rails and similar heavy sections. In order to obtain a uniform elongation of the individual parts of such complicated cross-sections, it is preferable to give a slight lateral pressure in the first shaping box passes. GN(12c)

The Development of Mechanical Cooling Beds. (Die Entwicklung der mechanischen Kühlbetten bis zu den Krupp-Hochleistungskühlbetten.) E. KÄSTEL. *Krupp'sche Monatshefte*, Vol. 11, Sept.–Oct. 1930, pages 255–265; *Iron & Coal Trades Review*, Vol. 121, Sept. 12, 1930, pages 360–361.
The article gives an illustrated description of modern cooling bed constructions which meet the requirements of large productions. GN(12c)

Design of Mills for Flat Flanged Beams. *Blast Furnace & Steel Plant*, Vol. 18, May 1930, page 832; June 1930, page 1034.
Outlines development of mills for rolling wide flanged beams. Most modern universal mill for this purpose is the Pulle mill. MS(12c)

Roller Bearings for Modern Cold Rolling Mills. (Ueber neuzeitliche Kaltwalzwerke mit Rollenlagern.) GUNNAR PALMGREN. *Stahl und Eisen*, Vol. 50, Dec. 25, 1930, pages 1805–1812.
After discussing the disadvantages of solid bearings, the correct selection of roller bearings is pointed out and various types of modern roller bearings are described and illustrated. Solid bearings and roller bearings are compared. The conclusions which are reached show the advantages of roller bearings. GN(12c)

The Development of the Sheet Bar Mill. (Die Entwicklung des Platinenwalzwerkes.) W. KRÄMER. *Stahl und Eisen*, Vol. 49, Nov. 14, 1929, pages 1653–1654.
The present practice in Germany is to roll sheet-bars in widths of 180, 200, 220 or up 250 mm. A new method is suggested for increasing the capacity of sheet-bar mills and decreasing the cost. GN(12c)

Improvements of Reels for Reeling Rods. (Neuerungen an Drahthaspeln.) W. KEHRMANN. *Stahl und Eisen*, Vol. 50, Dec. 25, 1930, pages 1816–1817.
The new type of reel which the author describes is a combination of a Garret reel and an Edenborn reel, which makes it possible to throw a reeled rod bundle vertically down on a conveyor. GN(12c)

Ball and Roller Bearing in the Steel Mill. D. E. BATESOLE (Norma-Hoffmann Bearings Corp.). *Rolling Mill Journal*, Vol. 4, July 1930, pages 353–358.
Discusses fundamental principles of mounting anti-friction bearings and some typical applications to equipment, such as roll necks, cut-off saws, table rollers and mill motors. MS(12c)

Forging (12d)

Forging Machine Practice. W. S. DEWELL. *Machinery* (London), Vol. 35, Feb. 20, 1930, pages 676–677.
Discussion of design of forging-machine dies for making torque tube flanges; includes an outline of 3 operations. (12d)

Construction of Dies for Forging. A. ALLEN (Angus Engineering Works). *Heating Treating & Forging*, Vol. 16, July 1930, pages 861–863.
Explains construction of dies for various types of forgings. MS(12d)

Manufacture of Large Steel Forgings. ADOLPH O. SCHAEFER (Midvale Co.). *Heat Treating & Forging*, Vol. 16, Jan. 1930, pages 43–47.
Outlines the different steps in the production of very large forgings and the special precautions taken. MS(12d)

Machining (12g)

Modern Cutting Tools for Machine Tools. J. B. RENNIE. *Edgar Allen News*, Vol. 9, Nov. 1930, pages 745–748.
Observations on cutting tools generally, with special reference to tipped tools. Author suggests a standard nomenclature applicable to all cutting tools for any machine tool. Considers the merits of the curved nosed and straight nosed roughers; the importance of side slope; the effect of back slope on side slope; the plan angle, for use on different materials; the diamond nosed tool; a standard roughing tool. W(12g)

The Lapping of Tungsten-Carbide Tools. H. J. WILLS (Carborundum Co.). *Machinery*, Vol. 36, May 1930, pages 718–719.
A lapped cutting edge on a tungsten-carbide tool has from 2 to 4 times the life of a ground edge. The process has not been generally used because of the high cost of diamond dust which costs from $9000 to $25,000 per pound. A working edge superior to that produced by diamond dust has been produced by an abrasive costing only 70 cents per pound. This is a carborundum finishing compound. The method of lapping with this abrasive is described in detail. RHP(12g)

Working Chromium-Nickel Alloys with Light Equipment. G. PARIOT. *Sheet Metal Worker*, Vol. 21, Nov. 28, 1930, pages 710–711, 714.
A recital of practical experience in working Cr-Ni alloys with light equipment. Special reference is made to difficulties in drilling and soldering these alloys. GN(12g)

Milk as a Coolant. JOHN KAPP. *American Machinist*, Vol. 73, July 10, 1930, page 45.
Milk has been used with good results with both carbon and high speed steel cutters. RHP(12g)

A Machine Tool Builders' Experience with Tungsten-Carbide Tools. *Iron Age*, Vol. 126, July 3, 1930, pages 10–13, 60.
Describes experiences of William Sellers & Co., Inc. Tungsten-carbide tools are carried in tool room from which operator can draw them upon proper authorization. New applications are followed up by the tungsten-carbide expert, and if adopted, the rate department adjusts piece work price. Written instructions are given operators. Proper grinding of cutting edge is very important. Clearance angles should be somewhat less than those for high speed steel. Hand grinding has been eliminated. Machine grinding permits use of water; grinding charts are used. Lapping after grinding will produce a keener edge. Tools chip and break if shank is too light, or too much Cu in the braze. Outstanding applications of the tools include planing of large ring gear segments on a 72 × 72 in. planes; planing 10 ft. boring mill uprights and planing beb of floor boring machine. Summarizes advantages and disadvantages of tungsten-carbide tools. VSP(12g)

Tooling for the Newer Metals. JOHN HAYDOCK, JR. *American Machinist*, Vol. 73, Sept. 18, 1930, pages 459–463.
Discusses the design of tools adapted to the cutting of the more recently developed alloys. Gives special requirements for each metal. RHP(12g)

Successful Use of Cemented Tungsten Carbide Demands Careful Study. J. GESCHELIN. *Automotive Industries*, Vol. 63, Oct. 18, 1930, pages 544–549, 559.
Survey of practical results in the use of cemented tungsten carbide tools. Detailed reference to rakes, angles and clearances of these tools. Grinding should be centralized and a careful operator selected who has proper equipment. GN(12g)

Our Experience with Tungsten-Carbide Tools. J. B. DOAN (American Tool Works Co.). *Machinery*, Vol. 37, Sept. 1930, page 6.
Carboloy tools used since Mar. 1929. Used for turning and boring column sleeves for radial drills, the columns themselves, column rings, rough-turning of lathe face-plates, turning cast Fe sleeves for both radial drills and lathes, machining semi-steel gear blanks. Discusses rate and depth of cut used. Savings have resulted from use of carboloy tools but they cannot be used successfully with out-of-date machines. RHP(12g)

Cutting Tests with Cemented Tungsten Carbide Lathe Tools. T. C. DIGGES. *Bureau of Standards Journal of Research*, Vol. 5, Aug. 1930, pages 365–368; *Engineer*, Vol. 150, Sept. 5, 1930, pages 247–249.
This investigation was made for the purpose of developing a method of testing cemented tungsten carbide lathe tools under heavy duty and to extend to the new cutting material some of the laws originally developed by Taylor and his associates for cutting with C and high-speed steel tools. Relations were determined between the speed, feed, depth of cut, and tool life for a selected form and size of tool. All tests were made dry in cutting 3.5% nickel-steel forgings, heat treated to give tensile strengths within the range of 85,000 to 110,000 lbs./in.^{2} The results are presented in both graphic and tabular forms. See extended abstract in *Metals & Alloys*, Vol. 1, Nov. 1930, pages 836–839. LFM+ESC(12g)

Tungsten Carbide—The First Product of a New Metallurgy. GREGORY J. COMSTOCK (Firth-Sterling Steel Co.). *Iron Age*, Vol. 126, Nov. 13, 1930, pages 1381–1383.
From a paper read before the National Metal Congress. Outlines the history, composition, characteristics and manufacture of tungsten carbide. VSP(12g)

Modern Metal Cutting Tools. *Engineering*, Vol. 130, Sept. 26, 1930, pages 400–401.
Editorial briefly reviewing the recent improvements made in cutting tools. Stellite, Cooperite, Widia, and tungsten carbide tools in general are discussed. Comments on paper read before the Detroit meeting of the American Society of Mechanical Engineers by T. G. Digges who gives results of an investigation on cemented tungsten carbide lathe tools. For these tests, the tungsten carbide tip was brazed on to a steel shank. Material tested was $3^1/_2$% Ni steel having tensile strength of 43 tons/in.^{2} Author attempted to work out relation of cutting speed and depth of cut to life of tool. LFM(12g)

Drawing & Stamping (12h)

Selection of Sheet Steel for Deep Drawing. W. H. GRAVES. *American Machinist*, Vol. 72, May 1, 1930, pages 718–719.
Criteria for workability and physical properties are discussed. See *Metals & Alloys*, Vol. 1, July 1930, page 633. (12h)

Die Pressing of Brass and Copper Alloys. JOHN R. FREEMAN, JR. (American Brass Co.). *American Institute Mining & Metallurgical Engineers, Technical Publication* No. 391, 1931, 8 pages.
Die pressings are made from almost all of the copper base alloys. A brass of about 60% Cu—2% Pb is frequently used on account of its good forging characteristics and excellent machinability. Parts are usually forged from pieces cut from extruded shapes. The presses may be of the drop, crank, or screw type. Various types of dies and parts made from them are described. JLG(12h)

How Ford Forms and Polishes Rustless Steel Radiator Shells. *Iron Age*, Vol. 125, June 26, 1930, pages 1887–1888.
In drawing rustless steel more pressure is required on the drawing ring than is the case with ordinary steel. Drawing rings are made of special cast Fe of close grain. All drawing surfaces are finished with a stone instead of an emery wheel. Seventeen operations are used in forming a radiator shell. Shells are polished with 180 mesh abrasive followed by a 200 and 244 mesh emery. Surplus pieces from pan are used for making small parts. VSP(12h)

Metal Stamping Dies. Parts XIX–XXI. ELLSWORTH E. CLARK (Westinghouse Elec. & Mfg. Co.). *Metal Stampings*, Vol. 3, Feb. 1930, pages 153–156, 164; April 1930, pages 323–328; Aug. 1930, pages 737–740, 744.
Discusses proper care and use of dies; factors affecting choice between built-up and solid types of die construction and applications, general construction, and advantages of pierce and sever or parting dies. MS(12h)

Blanking and Forming of Can Ends. H. F. BAYER (Continental Can Co.). *Metal Stampings*, Vol. 3, Jan. 1930, pages 55–56.
Two-part type of die is used for forming 2 complete can ends at each stroke of press. Blanking rings are made from Cromovan. The punches and the forming dies are made from 2 other kinds of steel. Each die receives 8 regrindings and one closing-up during its useful life. MS(12h)

Pickling (12i)

Formation of Hydrogen on Pickling. (Die Wasserstoffentwicklung beim Beizen.) H. BABLIK. *Korrosion und Metallschutz*, Vol. 6, Oct. 1930, pages 223–228.

Iron samples heavily scaled were pickled in hydrochloric and sulphuric acid and the hydrogen liberated was quantitatively measured. Instead of the conventional function $H = f(t)$ the author determined the reaction velocity $v = dH/dt = f'(t)$. The data are collected in 9 diagrams. The influence of inhibitors, the diffusion of hydrogen in both pickling acids, the influence of their concentration and of the temperature are considered. EF(12i)

Cold Working (12j)

Life of Cold-Heading Die Depends on Five Factors. A. S. JAMESON (International Harvester Co.). *Iron Age*, Vol. 126, Nov. 13, 1930, pages 1368–1369, 1436–1437.

Paper read before the American Society for Steel Treating at Chicago. Describes investigation on the maximum die life from certain type of cold-headed bolt die. Maximum production depends on die steel, die design, heat treatment, bolt material and machine operation. VSP(12j)

Should Steel Machinery Parts Be Cold Rolled? G. S. VON HEYDEKAMPF (Southwark Foundry & Machine Co.). *Iron Age*, Vol. 126, Oct. 2, 1930, pages 928–929.

Supplement of article published in *Iron Age*, Sept. 18, 1930. Cold working reduces elongation at fracture of tensile test pieces, and such elongation is considered a measure of ductility. Static ductility measures the ability of the material to withstand without fracture great plastic deformation at stresses near ultimate tensile strength. By cold rolling, not only is the fatigue strength increased, but endurance limit is shifted into a field of higher dynamic ductility. Results show that for 2 kinds of steels tested, the endurance limit increased about 15% and also dynamic ductility. VSP(12j)

Aluminum Spinning Practice. ROBERT J. ANDERSON. *Metal Stampings*, Vol. 3, June 1930, pages 513–517.

Equipment used and methods of tooling for Al spinning are practically the same as those for other non-ferrous metals. Higher speeds are possible with Al. Intermediate annealing is often necessary. Spinning is usually done on dead-soft annealed blanks of the commercially pure metal. Alloys are not generally used because they harden too rapidly. Heavier gages may be spun in Al than in other metals. Decribes operations involved, equipment and tools required, and applications. MS(12j)

Note on the Effect of Various Annealing Temperatures on Cold Worked Low Carbon Steel. H. E. PUBLOW. *Metals & Alloys*, Vol. 2, Jan. 1931, pages 18–19.

Cold working of steel is generally accompanied by an increase in the hardness. Theories offered in explanation of the property of hardness generally assume a decrease in the size of particles. This paper offers a study of automobile brake drums which show an increase in Rockwell hardness numbers as great as 30 points over the raw stock due to cold working. Photomicrographs are presented to indicate no decrease in crystalline size. Curves showing the relation between annealing temperatures and Rockwell hardness as well as annealing temperatures and ductility are included. The relation between hardness and ductility is also plotted. These observations indicate that the changes must be due to reactions within the grains themselves not revealed by the microscope. ESC(12j)

Cold Roll Forming of Metals. Part IX. D. A. JOHNSTON (McKinney Tool & Mfg. Co.). *Metal Stampings*, Vol. 3, Jan. 1930, pages 19–24; Feb. 1930, pages 121–126; March 1930, pages 229–234; April 1930, pages 331–334; May 1930, pages 429–434; July 1930, pages 621–627; Aug. 1930, pages 711–714; Sept. 1930, pages 795–798; Oct. 1930, pages 893–894, 896.

Outlines applications of the process, kinds of metals and types of products that can be rolled formed, and typical features of cold roll forming machines. Discusses capacities of, and specifications for the non-overhung and overhung types of machines. Describes method of rating capacities of machines which is based on the maximum dimensions of the section that the machine will handle, and various factors involved in selecting a suitable machine. Discusses design of rolls with reference to least distortion of metal, hardening and grinding, life and replacement, etc., and design of entrance guides, lifting shoes, and various types of straighteners. Outlines supplementary operations, such as shearing, bowing, coiling, welding of tubing, and manual and automatic cutoffs. Treats of roll design and figuring of stock for simple sections which involve curling and forming; and roll pass design and factors to be considered in forming of ribbed roofing sheets. MS(12j)

Cleaning (12k)

Value of Compressed Air in the Finishing Room. WILLIAM F. CAHILL. *Metal Cleaning & Finishing*, Vol. 2, June 1930, pages 523–524, 538.

Compressed air may be used as a means of agitating cleaning baths to make them function more efficiently. Its use is more advantageous for ferrous metals than for non-ferrous, because of the danger of oxidizing the latter. It can also be used to dry metal surface before finishing, so as to prevent formation of rust. MS(12k)

Straight-Line Cleaning of Castings on Conveyors. E. F. MILTENBERGER. *Iron Age*, Vol. 126, July 3, 1930, pages 5–9.

Supplementing article on molding and pouring practices, etc. published in *Iron Age*, March 27, 1930. Three transit conveyor lines with occasional short lines for special purposes, run the length of the cleaning department of the Eastern Steel Castings, Newark. A complete system of weighing and checking of weights pervades entire plant. Cleaning begins on the shake-out. From the main lines castings are switched off for grinding operations. Several types of grinders are used. Chippers work in twos, each on his own table, with inspector between the 2 tables. Castings are repaired en route. Sheet steel trays are used for sorting. VSP(12k)

Polishing & Grinding (12l)

Polishing Stainless Steel Sheets to Bring Out Their Gleaming Luster. *Iron Age*, Vol. 126, July 24, 1930, pages 213–216.

Describes method employed by the Republic Steel Corporation at Massillon, Ohio. Steel is melted in electric furnace. Proper amount of ferrochrome being added when poured from ladle. The hot rolled sheets received the Strauss heat treatment in continuous furnace. After annealing sheets are pickled in solution of HCl, physical tests are taken of each lot. Polishing is followed by a soft buffing with a compound made of grease and chrome oxide. For fine-finish polishing, grit coated rollers are used, which in addition to rotating, the rollers have an oscillating motion. Final operation consists in dipping sheets in solution of HNO_3 from 2 to 15 minutes. Fabrication of the sheets. VSP(12l)

Polishing Chrome-Nickel-Alloy Steel Requires Care and Special Compounds. CURTIS C. SNYDER (Republic Steel Corp.). *Iron Age*, Vol. 126, August 7, 1930, pages 353–356.

Grinding and polishing high Cr-Ni alloy steel requires special compounds and high-speed buffing to obtain best results. On exterior applications the Tampico brush gives a good finish. Iron oxide buffing compound is undesirable. Core required in roughing. Tabulates results of tests made to remove cement and plaster adhesions. VSP(12l)

Coloring (12m)

Relation between Color and Structure of Alloys. IV. Iron-Carbon Alloys. (Die Beziehungen zwischen der Farbe und dem Feingefüge der Legierungen. IV. Eisen-Kohlenstoff-Legierungen.) MASUMI CHIKASHIGE & DENZO UNO. *Zeitschrift für anorganische und allgemeine Chemie*, Vol. 190, May 30, 1930, pages 303–312.

After consideration of the theory of reflective power of Fe-C alloys, reflective power of pearlitic, martensite and Ledebur structures as a function of C contents, changing reflective power by heat treatment, the color of Fe-C alloys is concluded to be independent of the C content and the intensity of the color to be the differing quality. The designs developed by the polishing of Japanese swords are explained by the variation in the composition of the surface. (12m)

The Coloring of Cadmium. HUGO KRAUSE. *Metal Industry* (London), Vol. 37, July 25, 1930, pages 79–82; Aug. 1, 1930, page 109; *Metal Industry* (N. Y.), Vol. 28, Sept. 1930, pages 424–426; Oct., pages 475–477.

Translated from *Mitteilungen des Forschungsinstituts und Probieramts für Edelmetalle*, Vol. 3, pages 45, 56, 72 (1929), and Vol. 4, page 16 (1930). Experiments were carried out to determine which coloring methods available for other metals are applicable to Cd and what new processes of serviceable colored Cd finishes are to be achieved. Formation of CdO is particularly suitable for coloring this metal. An equally valuable compound is CdS. Halogen compounds cannot be considered as finishes. Results with chlorate solutions are given. Buchner recommends for Zn coloring a number of solutions whose action depends on separation of Cu by the dissolution of Zn and the conversion of the Cu film into Cu_2O or CuO and Cu_2Cl_2. The Czochralski black coloring method for Al consists in treating with ammoniacal CO solution and strongly heating. The permanganate bath is used in many varied compositions. The brown coloring processes tested were the Ebermayer, Buchner and the Japanese. Special methods for tinting Cd deposits. The permanganate-cadium nitrate baths can vary between wide limits. VSP(12m)

DEFECTS (13)

The Notch-Danger. (Ueber die Kerbgefahr.) W. KUNTZE. *Mitteilungen der deutschen Materialprüfungsanstalten*, Vol. 14, 1930, pages 71–77.

See *Metals & Alloys*, Vol. 1, Oct. 1930, page 802. (13)

The Failure of Flat Bottom Steel Rails. A. H. HUDDART (Egyptian State Railways). *Engineer*, Vol. 150, Dec. 12, 1930, page 650.

Discusses tests made to determine cause of failure by fracture of a large number of steel rails manufactured for the Egyptian State Railways. Failure occurred within one year of date of rolling. Table shows figures obtained by typical works tests and by hardness tests. Results show that "chilling" in rails of high Mn and C content is cause of fracture. Recommends control of cooling rate after rail leaves mill to obtain ideal combination of strength and hardness. Suggests that perfectly sound rail to give good track service will show higher degree of hardness in the "as rolled" state than in the "normalized" state. LFM(13)

Modern Billet Chipping Practice. ROBERT S. HAYDOCK & CARL LINDEN (Cincinnati Planer Co.). *Rolling Mill Journal*, Vol. 3, Dec. 1929, pages 511–514.

From paper read before the American Society of Mechanical Engineers in Akron, Ohio. Outlines various methods of chipping billets and describes types of milling, deseaming, and planing machines used. MS(13)

Transverse Fissures in Rails; Their Cause and Prevention. J. E. HOWARD. *Engineering News Record*, Vol. 103, Dec. 12, 1929, page 927.

Abstract of a report by the engineer-physicist of the Interstate Commerce Commission states that transverse fissures in rails are caused by excessive wheel loads, and that the remedy lies in finding some grade of steel which will best endure strains. (13)

Red-Shortness. (Ueber Rotbruch.) F. HARTLANEK. *Archiv für Eisenhüttenwesen*, Vol. 4, Oct. 1930, pages 207–214; *Stahl und Eisen*, Vol. 50, Nov. 20, page 1646

A charge of Mn scrap (1.7% to 1.8% Mn) was melted in a 300 kg. Heroult furnace and subjected to an ore oxidation succeeded by deoxidation with C. The whole course of the melting process was divided into an oxidation and a deoxidation period. After each of the 2 periods, deoxidation was accomplished by Al or Si or Mn. At the end of the oxidation period, the steel was to a large extent interspersed with inclusions. At the beginning of the introduction of C, the amount of inclusions decreased. They practically disappeared completely after some time but increased again at the end of the deoxidation period. The samples taken during the oxidation period show the tendency toward red-shortness at 1000° C., 1100° C. and 1300° C., but less pronounced at 1200° C. and 1250° C. The samples taken during the deoxidation period behaved differently, showing an increase of red-hortness with increasing temperature up to 1300° C. The temperature of most pronounced red-shortness decreases with decreasing C content. The tests indicate that there are 2 distinct temperature ranges of red-shortness which, according to Niedenthal's terminology are suitably called red-shortness in the lower temperature range and hot-shortness for the higher temperature range. The cause of blue-brittleness is traced back to oxidic inclusions. The cause of hot-shortness is seen in the influence of gases present. GN(13)

CHEMICAL ANALYSIS (14)

The Separation of Bismuth from Lead Containing Materials as BiOCl. (Bi-Trennungen von bleihaltigen Materialen als BiOCl.) W. HERTEL. *Metall und Erz*, Vol. 27, Nov. 1930, pages 557–560

Contains 2 references. For quick and accurate results the separation of Bi as BiOCl is better than the sulphate method. With 2 to 50 g. samples the volume of the solution can be kept down to 500 cc. The sample is dissolved in dilute HNO_3, neutralized with NH_4OH until Pb begins to precipitate, the Pb redissolved with dilute HCl and 1–3 cc. excess added. After heating, BiOCl is allowed to settle and filtered off. The precipitate is dissolved in 1:1 HCl, H_2SO_4 added and boiled to fumes of SO_3. After diluting Pb, if present, is filtered off and Bi precipitated with NH_4OH and $(NH_4)_2CO_3$. Cu and Pb are determined in the first filtrate. If Sb is present, the sample is dissolved in HNO_3, Sp. Gr. 1.33, and without filtering, BiOCl is precipitated, filtered off and dissolved in 1:1 HCl, neutralized with NH_4OH and the Bi separated with Na_2S. Pb, Cu, Sn and Sb can be determined in the filtrates. CEM(14)

A Method for the Separation of Lead and Bismuth. (Ueber ein Verfahren für die Trennung von Blei und Wismut.) H. BLUMENTHAL. *Mitteilungen der deutschen Materialprüfungsanstalten*, Vol. 13, 1930, pages 140–142.

See *Metals & Alloys*, Vol. 1, March 1930, page 431. (14)

New Reagent for the Qualitative and Quantitative Determination of Copper. (Ueber ein neues Reagens zur Qualitativen und Quantitativen Bestimmung des Kupfers.) FRITZ EPHRAIM. *Berichte der deutschen Chemischen Gesellschaft*, Vol. 63, Sept. 17, 1930, pages 1928–1930.

3 references. Cu can be precipitated quantitatively from acid solution by salicylaldoxim in the presence of any other metal. The greenish-yellow precipitate has the formula $(C_7H_6O_2N)_2$ Cu. The salicylaldoxim salts of all other metals are soluble in acid. The Cu solution is treated with NaOH until a precipitate begins to form, is acidified with acetic acid and the reagent is added at room temperature. The precipitate is filtered in a porous porcelain crucible, washed and dried at 100–105° C. It should not be heated above 115° C. It contains 18.95% Cu. CEM(14)

Operation of an Open-Hearth Steel Plant with the Aid of Time-Contracts. (Die Betriebsführung im Siemens-Martin-Werk mit Hilfe von Zeitgedingen.) O. CROMBERG. *Archiv für Eisenhüttenwesen*, Vol. 3, June 1930, pages 731–744; *Stahl und Eisen*, Vol. 50, July 1930, page 996.

A scheme is described in detail by which the wages of all employees in an open-hearth steel plant are based on the daily production. GN(16)

The Possibilities and Prospects for the Utilization of Canadian-Produced Copper in Home Manufacturing Industries. A. H. A. ROBINSON (Canadian Dept. of Mines, Mines Branch) & W. H. LOSEE (Dominion Bureau of Statistics). *Canadian Mining & Metallurgical Bulletin* No. 225, Jan. 1931, pages 149–184.

Canadian mines formerly exported as ore, matte, blister, etc., almost all the copper produced, forcing the manufacturers to import refined metal. The present movement of Canadian copper is traced and the history of Canadian refining developed. Exhaustive tables of imports and exports are given. The tariff on copper and its products entering Canada, United Kingdom, United States, Argentina, Brazil, Mexico, Belgium, France, Germany, Italy, Switzerland, Japan and China is tabularly presented. AHE(16)

Can Silver Come Back? W. F BOERICKE *Mining & Metallurgy*, Vol. 11, April 1930, pages 207–209.

A brief analysis of present demand and inquiry into stimulation of industrial uses. There was an increase in production from 1923 to 1928 amounting to 7.4% with slight falling off in 1929. For 1927 the average quotation was 56.37 cents, 58.17 in 1928 and 53.0 in 1929. In the U. S. and Canada 37 million ounces were used in 1929 in manufacture of silverware, silver plate, photography, etc. Demand for silver depends largely on economic conditions in the Far East. Domestic demand for silver appears insufficient. Production is over 60 million ounces and consumption only 39 million ounces. Main source of domestic demand comes from silverware manufacturers, photography film makers and chemical trade. Price reduction would have doubtful benefits. A real silver research program is needed. VSP(16)

The Present Radium Situation. R. B. MOORE (Purdue Univ.). *Mining & Metallurgy*, Vol. 11, Feb. 1930, pages 91–92.

Read before Rare Metals and Minerals Committee of the American Institute of Mining and Metallurgical Engineers, Feb. 1930. In 1914 the total amount of radium in the world was about 10 g. During early years of operation in this country the average grade of carnotite ore was about $2^1/_2$% and 3% U_3O_3. Torbenite and autunite have been found in South Australia. Uraninite and allanite found in Canada. Original mines in Czecho Slovakia are still productive. The real demand for radium is for cancer treatment. Much progress has been made in radium treatment of cancer. Considers cost of production and world output. VSP(16)

World Reserves of Tin and United States Consumption. *Information Circular* 6249, *United States Bureau of Mines*, Aug. 1930, pages 654, 673.

40% of the world virgin Sn is consumed in the U. S. and 99% of that domestically is imported. There are no domestic resources except scrap. Production of Sn from various sources for 1928 is given. ESC(16)

World Iron Ore Supply Apparently is Without Limit. CHARLES HART (Delaware River Steel Co.). *Iron Trade Review*, Vol. 86, April 10, 1930, pages 63–64.

Abstract of an elaborate paper on world's iron ore resources. On the basis of the researches of the foremost geologists, the addition of discoveries since their reports were made, and the deduction of the amount of ore consumed, it is estimated that actual and potential reserves at present are approximately: North America, 114 $\times$ 10^9 tons; South America, 8349 $\times$ 10^6 tons; Europe, 29 $\times$ 10^9 tons; Asia, 22 $\times$ 10^9 tons; Australia and New Zealand 991 $\times$ 10^6 tons; and Africa, 15 $\times$ 10^7 tons. The total is about 175 $\times$ 10^9 tons. MS(16)

Iron Ore Industry Speeds Up. A J. HAIN. *Iron Trade Review*, Vol. 86, Jan. 2, 1930, pages 32–35, 69.

Survey of the industry for 1929. Lake Superior mines were more active than in any year since the war. Leading companies sought to increase their reserves. Total ore shipments from region were 66,150,600 tons. MS(16)

Eight Operators Ship 89 Per Cent of Lake Superior Iron Ore. A. J. HAIN. *Iron Trade Review*, Vol. 86, Jan. 30, 1930, pages 55–57, 60.

Statistical survey of the Lake Superior iron ore industry. MS(16)

The Growth of the Steel Industry in Japan. (Entwicklung der Stahlindustrie in Japan.) H. FEY. *Stahl und Eisen*, Vol. 50, May 1, 1930, pages 598–601.

The author gives a summary of 4 papers presented at the World Engineering Congress at Tokio, 1929, which deals with the rise of the Japanese steel industry. The statistics given refer to the more important iron and steel works, the production of pig iron from 1914 to 1928, the composition of Japanese ores, iron as well as manganese ores, composition of coal and coke, the composition of pig iron and dimensions of blast furnaces of the more important plants. GN(16)

Silver, Copper, Lead, and Zinc in the Central States in 1929. J. P. DUNLOP & H. M. MEYER. *Mineral Resources of the United States*, 1929, Part I, *United States Bureau of Mines*, Jan. 10, 1931, pages 143–177,.

The mines of Arkansas, Illinois, Kansas, Kentucky, Michigan, Missouri, Oklahoma, and Wisconsin produced $110,979,243 worth of silver, copper, lead and zinc in 1929, an increase of about 16% over 1928. Other than silver which decreased about 4.7% in value, both the quantity and value of each of these metals increased over 1928, silver about 4.6% in amount, copper about 4.4% in quantity and about 28% in value, lead about 2.8% in quantity and about 11.6% in value, and zinc about 3.4% in quantity and about 11.9% in value. Copper production was all from Michigan except about 1 ton from Missouri. Missouri produced 73% of the lead. AHE(16)

Abstract of an official report. Includes statistics on production of ore, production of various types of steel and steel products, number of men employed, and amount of coal and coke consumed. RHP(16)

Economic Conditions in Turkey. *Iron & Coal Trades Review*, Vol. 121, Aug. 8, 1930, page 187.

Abstract of part of a report by Col. H. Woods issued by the (British) Dept. of Overseas Trade. Turkey is an important market for structural steel. Recent demand is lower due to use of reinforced concrete. Discusses imports and various uses of steel. RHP(16)

FOUNDRY PRACTICE & APPLIANCES (22)

Sand Control in the Steel Foundry. H. D. PHILLIPS. *Metals & Alloys*, Vol. 1, Oct. 1930, pages 759–762.

The moisture in molding sand should be so controlled as to allow proper molding and to avoid spraying of the sand after it is in the flasks which would naturally result in localized wet and impermeable spots. The permeability of the heap or backing sand should be greater than that of the facing sand. The compressive strength in lbs./in.^{2} should be great enough to allow quick and proper molding, without which it is possible that the sand may weaken and collapse. The grain size of the sand should be adjusted to give the desired surface on the casting. The silt, fines, and active bond should be held under 10%. ESC(22)

Application of Brass Ingot Metal in Industry. WILLIAM ROMANOFF & C. O. THIEME (H. Kramer & Co.). *Metal Industry* (N. Y.), Vol. 28, July 1930, pages 334–335, *American Metal Market*, Vol. 37, July 3, 1930 pages 3, 10.

From a paper read before the Cleveland Meeting of the American Foundrymen's Association, May 12–16, 1930. States that just as good results can be obtained from ingot as from virgin metal, and that it is more "fool proof" in its use in addition to effecting a saving. The metal may be remelted any number of times without deleterious results. VSP(22)

Shows Penetration of Steel Cast Against Sand. S. L. GOODALE. *Foundry*, Vol. 58, Aug. 1, 1930, pages 93–94.

Results of investigation of the action of molten steel in the sand mold. An abstract of paper presented before the 1930 convention of American Foundrymen's Association held in Cleveland. VSP(22)

A New Method of Making High Test Cast Iron, Chilled Casting, Malleable Iron and Steel in the Cupola. (Neuer Weg zur Erzeugung von Qualitäts-Grauguss-Hartguss-Temperguss und Flussstahl im Kupolofen.) LAMLA. *Giesserei Zeitung*, Vol. 27, Nov. 15, 1930, pages 621–623.

A new type of melting furnace is described which combines a cupola with an open hearth furnace. GN(22)

Separation and Cleaning Operations in Foundries. (Trenn- und Reinigungsarbeiten in der Giesserei.) M. KURREIN. *Zeitschrift für Metallkunde*, Vol. 22, Nov. 1930, pages 382–386.

Reviews the present state of treating of non-ferrous metals and alloys in foundry work by chisel, countersink-drill, saw and grinding operations as well as by sand blast. EF(22)

The Reclamation of Oil-Sand Cores. FRANK HUDSON (Fordath Engineering Co., Ltd.). *Foundry Trade Journal*, Vol. 43, July 24, 1930, pages 56–58; July 31, pages 78–80.

Paper read before the Institute of British Foundrymen. Considerable thought has been given to the problem, but successful application has still to come. Gives consensus of opinion existing in the United States relative to reclamation of oil-sand cores. Very little oil-sand core reclamation is practical in British Foundries. Benefits arising through reclamation of core sand must be considered individually by each foundry according to their particular practice. Points to be considered are: (1) Initial cost of core sand; (2) amount of oil-sand core used; (3) cost and kind of binder used; (4) nature of metal used for casting; (5) cost of disposal of waste sand; and (6) existing plant layout and type of castings made. Through reclamation a uniform sand free from gas and saving in binder costs is obtained. Effect of casting temperature on core sands in regard to splitting up of sand grains is important. Practical reclamation methods are discussed. For grading, the electric vibrating type of screen is used. VSP(22)

Using Off Peak Power for Melting Gray Iron. W. R. JENNINGS. *Metals & Alloys*, Vol. 1, Nov. 1930, pages 814–815.

The Baker Perkins Co. of Saginaw, Michigan, is operating a rocking type of electric furnace for converting iron borings into high strength irons. Since the increased demand charge would require a cost of $9.44 to $10.03 per net ton, the operation time was changed to the hours of 4:00 to 12:00 P. M. and a saving of $5500 per year results. ESC(22)

Mechanical Cupola Charging. CLEMENT A. HARDY (Whiting Corp.). *Iron Age*, Vol. 125, Nov. 6, 1930, pages 1306–1308.

Describes several forms of machines for better distribution of charge such as side-dump charges, bottom-dump cars, skid hoists and other devices manufactured by the Whiting Corporation. VSP(22)

Britain's Bell Foundries. Notes on the Present State of Ancient Craft. J. R. NICHOLS. *Metal Industry* (London), Vol. 36, June 6, 1930, pages 597–600; June 13, 1930, pages 621–623; Vol. 37, July 4, 1930, pages 3–5.

Gives a description of bell founding and some famous British foundries. VSP(22)

Oil Sand Cores Used in Casting Alloy Steel Chains. J. C. PENDELTON. *Foundry*, Vol. 58, June 1, 1930, pages 159–162.

Describes manufacture of chains as practiced at the Norfolk Navy Yard to meet navy specifications. Following physical requirements are needed: tensile strength 100,000 lbs./in.^{2}; yield point 60% of ultimate tensile strength; reduction area 18% and elongation in 2 in., 10%. All above requirements are minimum. Chains are cast in dried oil sand molds and consist of 2 operations. Pattern work is in form of core boxes. Test chains are heat treated at same time and same furnace as chain shots which they represent. VSP(22)

On the Fundamental Study for the Production of Low Carbon Semi-steels from the Stand Point of Cupola Operations. (Part 2.) MASAYASU HORIKIRI. *Tetsu to Hagane*, Vol. 16, Sept. 25, 1930, pages 935–960; Oct. 25, 1930, pages 1063–1086.

In the present paper, the writer reports the result of an investigation on the production of low C semi-steels on a large scale. As materials, pig Fe and mild steel scrap were used and melted together in a large cupola, 900 mm. in the diameter at the melting zone. The temperature in the inner part was measured. The combustion gas at that place was taken and CO_2, CO and O_2 were determined. The results thus obtained clearly showed that the C in semi-steels is absorbed by contact of red-hot coke with the molten Fe. It is, therefore, necessary to use the minimum quantity of charged coke and to reduce the oxides in the charge with Si in order to obtain the low C semi-steels. Moreover, the molten Fe containing high Si dissolves only a small amount of C, so that high grade low C semi-steels, generally, contain much Si. After the experiments under the several conditions at the melting zone, the writer concluded that the oxidation of Fe by gases gradually decreases from the tuyère level to the upper part, and increases on approaching the furnace wall but decreases at the center part. The relation between the depth of the cupola hearth and the C absorption of molten Fe was studied and it is shown that there are no remarkable relations between the m. When many tuyères with small sectional area are used and the blast is passed through at high speed, the conditions are satisfactory, the atmosphere in the melting zone being oxidizing and considerable C absorbed by the melt. On the other hand, with large sectional area and small numbers of tuyères the atmosphere is reducing and the absorption of C decreases. The C content in the product depends on the contact condition of the gases with the melt and red-hot coke at the melting zone, that is, the oxidation takes place by the gases, according to the following: $2Fe + O_2 \longrightarrow 2FeO$, or $Fe + CO_2 = FeO + CO$, and the reducing by the red-hot coke, thus: $FeO + C = Fe + CO$, $2FeO + Si = Fe + SiO_2$ and $SiO_2 + C = Si + CO_2$. TS(22)

Steel Castings. T. M. SERVICE. *Foundry Trade Journal*, Vol. 42, April 10, 1930, pages 266–268; April 17, 1930, pages 291–292; Discussion, May 1, 1930, pages 323–324.

Paper read before the Scottish Section of the Institute of British Foundrymen. Steel when cooling evolves gas, contracts in volume, contracts superficially and several of its constituents segregate. Defects found in castings are: (1) blowholes; (2) piping; (3) hot tears and tension cracks; and (4) segregates. Al is added to steel to reduce blowholes. Blowholes may be of three types: (*a*) Completely dispersed through mass; (*b*) Blowholes occurring below the skin surface and extending from 1/8 to 1/2 in. deep. Recent determination of density of steel at temperature 1480–1500° C. is given as 7.0. Loss due to excess metal required for heads varies between 30 to 40%. Superficial contraction was determined in acid and basic steel. Composition:

	C	Si	Mn	S	P
Acid	0.28–0.50	0.22–0.60	0.26–0.60	0.036–0.085	0.063–1.106
Basic	0.15–0.39	0.32–0.47	0.49–1.80	0.021–0.045	0.014–0.047

Hot tears are due to excessive stress applied in the plastic range. Tension cracks occur in castings which have a rapid change of section. Cracking takes place generally at about 100° to 300° C. Gives a number of tables and illustrations. VSP(22)

Modern Core-Making Practice. C. WOOD. *Foundry Trade Journal*, Vol. 42, April 24, 1930, pages 304–306.

Paper read before the Sheffield branch of the Institute of British Foundrymen. Cores are used to provide holes, recesses and openings in finished castings. Gases formed in mold pass out through these cores and not through the metal. Points to be considered in core production are: (1) Class and density of sand used; (2) bond of the sand; (3) weight and size of core; (4) thickness and general contour of the casting for which it is used; and (5) drying temperature of core. New type of machine now on the market is known as a perfect core machine, by which all types of cores can be made. It will permit the use of interchangeable core boxes. Suitable for making round, half-round, chamber, square and similar shaped cores. Any mixture of sand may be used. Sands for core making must possess cohesion and strength. The best known binder is linseed oil. Slow drying of cores, with efficient and complete temperature control, results in improved cores. Temperatures of from 225° to 265° C. are used for sections to 2 in. thick and 200° to 220° C. for sections heavier than 2 in. thick. Considers oil sand practice and methods for testing sands. VSP(22)

Cast Iron Research and Foundry Practice. (Gusseisenforschung und Giessereipraxis.) LOHSE. *Zeitschrift Verein deutscher Ingenieure*, Vol. 74, July 5, 1930, page 944.

Report on some of the papers read before the Convention of the Verein deutscher Giessereifachleute. Osann shows that high-grade cast-iron is the same as eutectic cast iron; this iron possesses good flowability, little tendency to form pipes and good workability. Foundries should, therefore, aim to produce eutectic cast-iron by proper proportioning of the contents of carbon and silicon. F. Roll discussed the hardness of cast-iron as dependent on temperature and the fairly complex relations between hardness, carbon content, temperature and time. Bardenheuer reported on recent results of American research of the physical properties of cast-iron for which a classification according to the content of carbon and silicon has been proposed. Ha (22)

Long-Life Molds and Their Uses. RICHARD MOLDENKE. *Iron Age*, Vol. 125, May 1, 1930, pages 1292–1293.

No material of construction known, which serving as a container for molten metal, will not eventually break down under the extremely high temperatures. "Permanent" mold is a misnomer; "Long-life" is preferable. Molten metal coming in contact with sand or metal mold surfaces has a two-fold effect: (1) Washing away of such surfaces in part, and (2) destruction of surfaces due to high temperatures and consequent penetration of metal. Metal molds with refractory coatings are the most promising development. Most refractory material for long-life molds is gas carbon. VSP(22)

Duplexing with Cupola Makes High-Grade Iron Castings. H. E. BROMER (Standard Foundry Co.). *Iron Age*, Vol. 125, May 8, 1930, pages 1372–1376.

Describes method employed by the Standard Foundry Co. The cupola, a standard No. 7 Whiting, is charged in same way and with same materials as formerly, with the exception that coke was cut to 135 lb. to the ton. After about 8 or 10 min. the first iron starts coming over the spout. This runs directly into the electric furnace and remains there without power until two taps have been run in. The bath is brought to a temperature of about 3000° F. The advantages of the electric process are the uniformity and quality of the iron produced. Test bars show a transverse test of 4800 lbs. with a deflection of 0.13 in. Tensile tests showed an average strength of 40,000 lbs./in.^{2} Alloy irons also produced. Impact values obtained for plain iron are approximately twice as high as for the cupola product. Brinell hardness is practically the same throughout the casting. Costs are materially lowered. VSP(22)

Malleable Cast Iron, Part 3, Comparison of Melting Practices. J. V. MURRAY. *Metallurgia*, Vol. 2, July 1930, pages 101–102; Part 4, Oct. 1930, pages 215–217.

Discusses various furnaces used in melting malleable iron. The cupola is fast and satisfactory when everything is working right. The crucible process is only satisfactory for experimental work and for producing very small castings. The open-hearth furnace produces a good metal, but at a high cost. Electric furnaces, particularly the induction furnace, have cost as their only disadvantage. The rotary furnace has recently been introduced, and is a good, cheap melting furnace. Several duplex processes are mentioned. JLG(22)

The Fundamentals of Brass Foundry Practice. Part 23. R. R. CLARKE. *Metal Industry* (N. Y.), Vol. 28, May 1930, pages 221–222.

Two main difficulties attend Cu molding: (1) High and local shrinkage; (2) obtaining clean metal free of scum and dross of the metal's own making. Oxidation and gasification are very prominent in Cu. Overcoming them, and where electrical conductivity requirements are not high, 2% Zn and trace of P are added. Addition of Mg to Cu does not interfere much with conductivity. Describes method of molding. VSP(22)

A Special Bronze Casting Problem. JOSEPH P. MCGINNIS (E. R. Caldwell & Sons Co.). *Metal Industry* (N. Y.), Vol. 28, May 1930, pages 212–213.

Describes the molding of a hub disc for a 3 in. slurry pump made for the Morris Machine Works, Baldwinsville, N. Y. VSP(22)

Foundry Problems. H. HURST. *Foundry Trade Journal*, Vol. 42, April 24, 1930, pages 312–313.

Paper read before Scottish Branch of the Institute of British Foundrymen. Deals with foundry organization rather than making of any special castings. Takes up the following features: the type of work; situation of works; hand or machine molding; foundry personnel; staff and ordinary labor; type and quality of patterns; melting equipment; sand preparation plant; corestoves; and commercial end of the business. VSP(22)

Building a Mould in Sections for a Machine Base. J. BENNETT. *Foundry Trade Journal*, Vol. 42, May 1, 1930, pages 330–332.

Includes discussion. Paper read before the Wales and Monmouthshire Branch of the Institute of British Foundrymen. Describes methods employed in the construction of the mold. Gives a number of illustrations. VSP(22)

FURNACES & FUELS (23)

Electric Resistance Industrial Furnaces. VICTOR PASCHKIS. *Heat Treating & Forging*, Vol. 16, March 1930, pages 376–380.

Translated from *Stahl und Eisen*. MS(23)

Gas Modernizes Forging. C. B. PHILLIPS (Surface Combustion Co.). *American Gas Journal*, Vol. 132, Apr. 1930, pages 73–74.

Description of a furnace known as continuous billet-heating furnace which is of the double-row type, using 2 pneumatic pushers. It is 24 1/2 ft. long, 6 ft. wide and about 20 in. high from skid rails to spring line of arch, internal dimensions; of brick construction, the whole is encased in steel plates and supported by buck stays; the walls are 13 1/2 in. thick and consist of 9 in. of firebrick and 4 1/2 in. of insulation. Low-pressure gas is used and there are 8 water-cooled burners. (23)

The Coreless Induction Furnace in a New Role. A. G. ROBIETTE. *Iron & Steel Industry & British Foundryman*, Vol. 4, Jan. 1931, pages 125–129.

Experiments were made to determine the possibilities of refining low-grade steel scrap of various compositions and of pig irons, the extent of the elimination of the elements silicon, manganese, phosphorus, carbon and sulphur under varying conditions, and the speed of elimination. Silicon is removed as rapidly as ore is charged. Dephosphorization is rapid and quite complete under suitable slag conditions. Carbon removal is rapid in both the slag reaction process and the air blast method. Sulphur removal is generally erratic, it increases with the fluorspar addition. Products of deoxidation are removed in a few seconds through rapid circulatory motion of the charge. An auxilliary arc above slag surface to keep it fluid is suggested. CHL(23)

Factors Influencing the Design of Normalising Furnaces. E. E. GRIFFITHS. *Metallurgia*, Vol. 3, Dec. 1930, pages 62–64 and 68; *Iron & Coal Trades Review*, Vol. 121, Dec. 5, 1930, pages 835–837.

Lengthy abstract of paper before Wales branch of the Institute of Mechanical Engineers. Considers furnaces for normalizing sheet and tin-plate. JLG(23)

Developments in Sheet Mill Practice. EDWARD S. LAWRENCE. *Blast Furnace & Steel Plant*, Vol. 18, Aug. 1930, pages 1301–1302, 1306; Sept. 1930, pages 1455–1460.

Review of recent United States patents on continuous pair and pack furnaces, rolling-mill equipment, normalizing and annealing furnaces, pickling machines and annealing-boxes. MS(23)

REFRACTORIES & FURNACE MATERIALS (24)

Development of Modern Refractories. H. E. WHITE. *Fuels & Furnaces*, Vol. 8, Jan. 1930, pages 107–110.

Presents brief review of the first crude refractories of ancient times and the development of alumina, silicon carbide, and mullite refractories and graphite crucibles. MS(24)

Testing Refractory Cements. CHARLES MCMULLEN. *Fuels & Furnaces*, Vol. 8, March 1930, pages 358–359.

Abstract of paper read before the American Ceramic Society, Feb. 16–21, 1930. Developed a small test furnace, heated electrically with "Globar" non-metallic resistor heating elements, which attains a maximum temperature of 1500° C. Includes transverse and load testing equipment. Tests were made by: (1) Heating test bar to temperatures, holding for 4 hrs., then breaking (transverse) at this temperature; (2) same as (1), except that bar is broken cold; and (3) heating bar to temperature, holding for 5 min., and breaking at this temperature. Test (1) gives strength of cement after it is in use at a certain temperature; test (2) gives strength after cooling; and test (3) gives strength on initial firing in use. Presents results obtained with a high-grade commercial cement. MS(24)

Refractories for Open-Hearth Furnaces. *Blast Furnace & Steel Plant*, Vol. 18, June 1930, pages 999–1001.

Discusses materials and construction that are most satisfactory. Checker chambers are usually built of a good grade of fire-brick and these should be used throughout the flues to the stack. Chambers should be insulated with 4 1/2 in. of insulating brick. Fantail arches of furnaces should be installed with clay brick and covered well. Silica brick should be used to support the fantails. Clay brick are generally used in the walls of slag pockets to about the height of the slag line, and silica brick from this point up to the roof of the furnace. Chrome brick are being used to a great extent in gas-port linings. In the last 10 years chrome brick have replaced magnesite brick for bottom, though many operators still use the latter. Furnace crowns do not run the full life of the furnace. Rib roofs and heavy construction are used to prolong the life of crowns. MS(24)

Refractory Materials. COLIN PRESSWOOD. *Blast Furnace & Steel Plant*, Vol. 18, May 1930, pages 838–840.

From *Metallurgia*, Nov. 1929. See *Metals & Alloys*, Vol. 1, Aug. 1930, page 684. MS(24)

Silicon Carbide and Mullite. HAROLD E. WHITE (Lava Crucible Co.). *Blast Furnace & Steel Plant*, Vol. 18, May 1930, pages 840, 842.

From *Mining & Metallurgy*. MS(24)

Study of Checker Brick. R. M. KING (Ohio State University). *Blast Furnace & Steel Plant*, Vol. 18, May 1930, pages 837–838.

Paper read before the American Ceramic Society, Feb. 1930. Progress report. Presents results of a laboratory investigation of the porosity, P. C. E. values, heat transfer, and uniformity of dimensions of 10 1/2 × 4 1/2 × 4 1/2 in. and 9 × 4 1/2 × 2 1/2 in. brick. Tests were carried out on bricks from Ohio, Pennsylvania, Kentucky, and Missouri, and made by the soft-mud, stiff-mud, and dry-press processes. MS(24)

Metallurgical Refractories. *Iron & Coal Trades Review*. Vol. 121, Aug. 1, 1930, page 160.

Practically the same as the article by H. E. Townsend entitled "Refractory Brick and its Manufacture," published in *Blast Furnace & Steel Plant*, Vol. 18, Jan. 1930, pages 105, 195–196. Also published in *Heat Treating & Forging*, Vol. 16, Feb. 1930, pages 193–195. RHP(24)

Refractories. R. M. DOIDGE (Morgan Crucible Co., Ltd.). *Blast Furnace & Steel Plant*, Vol. 17, Dec. 1929, pages 1854, 1857–1858; Vol. 18, Feb. 1920, pages 345–346, 349–350; Condensed in *Heat Treating & Forging*, Vol. 15, Dec. 1929, page 1632; Vol. 16, Jan. 1930, page 112.

Paper read before the Swansea Section of the Institute of Metals. Discusses the causes of the premature failures of refractories and the means of overcoming them. Chief causes are lack of refractoriness; shrinkage or expansion in use; softening under load; mechanical erosion or breakage; cracking or spalling; and erosion by slags or fluxes. Deals briefly with refractories for special uses. MS(24)

Increasing the Life of Furnace Brick Work. *Blast Furnace & Steel Plant*, Vol. 18, June 1930, pages 1011–1012.

Walls may be repaired with a refractory mixture made of pulverized clean brick salvaged from dismantled furnaces and a suitable bonding material. This is mixed with H_2O and applied to the furnace linings by means of a cement gun. The factor which requires the most careful investigation is the constituency of the mixture to be used in various types of furnaces and under various conditions. Discusses several batches. MS(24)

GASES IN METALS (25)

Influence of Nitrogen in Electric Arc Fusion-Welding. (Einfluss des Stickstoffs bei der elektrischen Lichtbogen-Schmelzschweissung.) JULIUS FUCHS. *Zeitschrift Verein deutscher Ingenieure*, Vol. 74, Nov. 15, 1930, pages 1569–1572.

The following table illustrates the results of tests to find the harmful influence of N on welded seams. The type of electrode is of great importance; the better it is covered, the less N is absorbed.

Sample No.	Type of electrode	Burning depth mm.	Brinell hardness kg./mm.²	Nitrogen contents %	Quality of weld
1		1.6	67.8	0.048	
1	Thickly	2.0	64	0.034	Forgeable
2	covered	2.2	56	0.054	
2		2.5	54	0.060	
3		2.0	64	0.064	
3	Asbestos	2.3	64	0.070	Forgeable
4	covered	2.3	64	0.058	
4		2.5	61.5	0.054	
5		1.9	59	0.075	
5		2.0	61	0.080	
6	Bare, with	2.4	62	0.103	Forgeable
6	non-	2.4	59	0.105	
7	metallic	2.0	56.5	0.097	
7	core	1.9	51.8	0.090	
8	Dipped	2.1	59	0.129	Not forgeable
8		2.2	71.2	0.150	
9	Charcoal	2.1	71.2	0.149	Not forgeable
9	wire	1.5	61.5	0.130	
10	Thinly	2.2	71.2	0.150	Not forgeable
11	covered	2.7	64.3	0.129	

For high-grade welds, i. e., all connection welds, the forgeability should also be taken into account in order to avoid inclination to fractures. Ha(25)

Causes of Unsoundness in Bronze Castings. J. DANIELS. *Fuels & Furnaces*, Vol. 8, May 1930, pages 627–630; *Journal of Institute of Metals*, Vol. 43(1930) pages 125–162.

From paper read before Institute of Metals. See *Metals & Alloys*, Vol. 1, Sept. 1930, page 744. MS(25)

Adsorption of Hydrogen by Nickel at Low Temperatures. ARTHUR F. BENTON & T. A. WHITE. *Journal American Chemical Society*, Vol. 52, June 1930, pages 2325–2336.

Presented before the Division of Physical and Inorganic Chemistry at the Columbus Meeting of the American Chemical Society, April 1929. At a given pressure the adsorption is relatively large at the lowest temperatures, decreases to a minimum at −200° to −175° C. depending on the pressure, then rises to a maximum at about −100, and finally decreases again at higher temperatures. At 600 mm. the adsorption is independent of the temperature from −100° to 0°. At −191° and −183° the adsorption increases with pressure in a discontinuous manner. Interpretations are made as to the type of adsorption at high and low temperatures. MEH(25)

The Occurrence and Determination of Gases in Metals. JULIUS GRANT. *Metal Industry* (London), Vol. 37, Sept. 26, 1930, page 292.

Cites researches of a number of investigators and briefly discusses the results of their work. VSP(25)

Treating Aluminum Alloys with Volatile Chlorides. W. ROSENHAIN, J. D. GROGAN & T. H. SCHOFIELD. *Iron Age*, Vol. 126, Oct. 9, 1930, page 985.

Abstract of paper read before the Institute of Metals. See "Gas Removal and Grain Refinement of Aluminium Alloys," *Metals & Alloys*, Vol. 1, Nov. 1930, page 856. VSP(25)

Solubility of Oxygen in Solid Iron. (Löslichkeit des Sauerstoffs in festem Eisen.) W. BISCHOF. *Stahl und Eisen*, Vol. 50, Jan. 2, 1930, pages 18–19.

The author reviews the 8th installment of R. Schenk's and his collaborator's investigations on the reduction, oxidation and carburization process for Fe as published in the *Zeitschrift für anorganische und allgemeine Chemie*, Vol. 182, 1929, pages 94–117. Reference is also made to an investigation by W. Krings and J. Kempkens on the same subject, published in the *Zeitschrift für anorganische und allgemeine Chemie*, Vol. 183, 1929, pages 225–250. The results of both investigations are in much better agreement with the general opinion on the solubility of O in solid Fe than former investigations. See also *Metals & Alloys*, Vol. 2, Jan. 1931, page 17. GN(25)

INSPECTION (26)

Hot Acid Test for Tool Steel. *Heat Treating & Forging*, Vol. 16, June 1930, pages 747–749.

From a bulletin issued by the Research Department, Carpenter Steel Company. See editorial, "A New Era in Advertising," *Metals & Alloys*, Vol. 1, July 1930, page 587. MS(26)

Metal Pellets, Produced by Spark Tests, Used to Identify Alloy Steels. WALTER G. HILDORF & C. H. MCCOLLAM (Timken Roller Bearing Co.). *Iron Age*, Vol. 126, July 3, 1930, pages 1–4.

A further elaboration of an article in *Iron Age*, Oct. 10, 1929. Pellet test for alloy steel indentification gives valuable possibilities as an adjunct to spark test. Pellets are globules driven off by grinding wheels, but not affected by heat or chemical reaction. Method of separating pellets from turnings is given. Pellets from various alloys vary greatly in shape, texture and color of their surfaces. C content of plan C steels has but little effect on pellet characteristics. Cr makes pellets gray and round, alloys of Va group are very easily indentified by pellet test. The pellets are jet black and surfaces are heavily pitted, with somewhat polished appearance. Mo alloys offer an example of the interlocking of the spark and pellet tests. Mo spark characteristics are obscured but the pellet characteristics are easily distinguishable. Pellets from carburized steels show great accentuation of alloy characteristics. Preparation and use of standard pellet slides is essential. Table of comparative fields of spark and pellet tests in sorting alloys steels:

Steels	Spark Test	Pellet Test
1015 and 1095	Yes	No
4615 and 1095	Yes	No
1015 and 4615	Yes	No
1095 and 52100	Doubtful	Yes
1045 and 5145	Doubtful	Yes
6195 and 52100	Doubtful	Yes
6195 and 1095	Doubtful	Yes
4195 and 6195	Doubtful	Yes
4195 and 52100	Doubtful	Yes

VSP(26)

Specifications and Materials Control. H. A. BACKUS. *Proceedings American Society for Testing Materials*, Vol. 30, Pt. 2, 1930, pages 109–118.

Discussion appended. See *Metals & Alloys*, Vol. 1, Sept. 1930, page 745. (26)

MANUFACTURERS' LITERATURE REVIEWS

In this department we each month list the catalogs and other printed matter issued by manufacturers. Unless otherwise noted, any of the items listed may be secured free upon application to the issuing firm. Manufacturers who have not yet sent in their printed matter are invited to do so.

301 **Annealing Furnaces.**—The Westinghouse Electric & Mfg. Company, East Pittsburgh, Pa., has just released a leaflet describing their rectangular and cylindrical bell type annealing furnaces. The advantages of these furnaces are close temperature control, controlled atmosphere and simplicity of operation.

302 **Die Casting Handbook.**—The object of this handbook is to supply general information to engineers who are already familiar with the die casting process. It contains data on the Stewart Die Casting Alloys. Stewart Die Casting Corporation, 4535 Fullerton Avenue, Chicago, Illinois.

303 **Nickel Alloy Steel Products.**—The International Nickel Company, Inc., 67 Wall Street, New York, N. Y., has published a 16-page Buyers Guide to these products, which is a tabulation of sources of supply for the more commonly used forged, rolled, cast or drawn products made from Nickel Steels and Alloys. This edition contains footnotes concerning the size ranges and production limitations of the various concerns listed.

304 **Electroplating Aluminum.**—This instructive booklet issued by the Aluminum Company of America, Pittsburgh, Pa., gives in great detail the method of plating aluminum using different deposits. Several plates and tables make the book even more complete.

305 **Inspection.**—An attractive and well-planned booklet issued by the Pittsburgh Testing Laboratory, Pittsburgh, Pa., brings out the value of careful inspection of materials used in all construction.

306 **Manganese Steel.**—The November issue of the Amsco Bulletin, issued by the American Manganese Steel Company, Chicago Heights, Ill., contains an interesting article on manganese steel sheaves as a means of saving rope as well as illustrations of manganese steel stone quarrying machine parts.

307 **Nirosta KA2 and KA4.**—The Associated Alloy Steel Company, Cleveland, Ohio, has printed three more pamphlets in their Technical Bulletin Series. These are: Resistance of Nirosta KA2 and KA4 against Chemical Attack, The Physical Properties of Nirosta KA2 and Fabrication of Nirosta.

308 **Plating Machines.**—Bulletin No. 313 is a very thorough discussion of the Meaker Straight-A-Way and Return Type Machines, indicating the economies effected by the use of this equipment. The Meaker Company, 1615 South 55th Avenue, Chicago, Illinois.

309 **Refractories.**—The E. J. Lavino and Company, Philadelphia, Pa., had a competent engineering firm survey their Plastic K-N and Kromepatch while in actual use. Copies of these surveys, LC-104-CZ, LC-109-AZ and LC-102-HZ, can be obtained upon request.

310 **Automatic Control.**—This booklet describes and illustrates how automatic control renders its aid as though it were humanly directing your process to meet changing operating conditions and requirements freeing the human element from its limitations. Brown Instrument Company, 4482 Wayne Ave., Philadelphia, Pa.

311 **Bearing Tester.**—This is a leaflet describing an acoustimeter for the inspection of ball and roller bearings. The function, operation and advantages of the Burgess Bearing Tester are also given. Burgess-Parr Company, 111 West Monroe St., Chicago, Ill.

312 **Pyrometers.**—Potentiometer pyrometers made by the Leeds & Northrup Company, Philadelphia, Pa., are accurate and well capable of withstanding rough service. They are described in a leaflet issued by the company.

313 **Refractories.**—A recent issue of *Grits & Grinds*, published by the Norton Company, Worcester, Mass., reprints an interesting article from Industrial Gas entitled "Alundum Refractories in Some Modern Gas Furnaces." A 16-page booklet issued by the company tells the whole story of the new Norton markings and "What is Controlled Structure?"

314 **Nickel Cast Iron.**—The December issue of this periodical published by the International Nickel Company, 67 Wall Street, New York, contains a brief history of cast iron, one of the series of Intimate Chats on Metallography and several important applications of nickel cast iron.

315 **Electrical Equipment.**—The General Electric Company, Schenectady, New York, has issued a number of new leaflets to be inserted in their GEA folder. These describe Resistor Arc Welders, Hand Starting Compensators, Fan-cooled Induction Motors, Magnetic Switches and Oil Circuit Breakers.

316 **Special Furnaces.**—A four-page folder sent out by the Surface Combustion Company, 2375 Dorr Street, Toledo, Ohio, describes an SC Car Bottom Annealing Furnace installed in the plant of the Link Belt Company.

CURRENT METALLURGICAL LITERATURE ABSTRACTS OF METALS & ALLOYS

PUBLISHED MONTHLY BY THE CHEMICAL CATALOG COMPANY, INC.

419 Fourth Ave., New York

Editorial and Advertising Offices: 3619 Forbes Street, Pittsburgh, Pa.

Annual Subscriptions: U. S., Possessions, Mexico and Cuba, $3.00; Canada, $3.50; Other Countries, $4.00; Single copies, 40¢.
Copyright, 1931, by The Chemical Catalog Company, Inc. All rights reserved.

Note. The September issue of METALS & ALLOYS will be Vol. 2, No. 3. For purposes of binding and filing, these monthly bulletins may be considered as Vol. 2, No. 2a, 2b, etc

These abstracts are not critical, but merely review developments. The classification number at the end of each abstract will be of assistance in mounting them on filing cards.

Negative print photostats of the original articles abstracted below can be obtained at 35 cents per page, plus 10 cents for mailing first class.
The remittance should accompany the order.
Book Reviews are included below and marked by -B-

CONTENTS—APRIL 1931

PATENT SERVICE

Until we resume regular publication in September, the service rendered by the Patent Department of METALS & ALLOYS will be carried on by Mr. W. M. Corse, 810 Eighteenth Street, Washington, D. C. who can supply copies of United States and foreign patents and translations at reasonable costs.

GENERAL (0)

Mitteilungen aus den Forschungsanstalten des G-H-H Konzerns. Published by V. D. I. Verlag, G. m. b. H., Berlin. Price about 2.50 RM per issue.

This new metallurgical journal had its first appearance in the fall of 1930. It is to contain articles from the testing laboratories of 11 German firms, headed by the Gutehoffnungshütte Oberhausen Aktiengesellschaft, including several machine shops and foundries, the Osnabrücker Kupfer und Drahtwerk, Eisenbahn Essen, etc. It carries no advertising.

The articles are apparently not to be of the highbrow type, recording the long and exact scientific laboratory work that we find in many German periodicals but are instead written from the works laboratory point of view, reflecting the attitude of the practical German metallurgist. Some of the articles read as though the author was letting off steam in defense of his own beliefs, and some approach being propaganda for the products of the firm from whose laboratory the article emanates.

The articles are interesting, but it may be well to recall the possibility that they may be written from the point of view of a man with an axe to grind.

The journal is to appear "every little while" (in zwangloser Folge).—H. W. Gillett (0)

Electro-motive Force and Polarisation. (Handbuch der allgemeinen Chemie. Elektromotorische Kräfte Elektrolyse und Polarisation.) Vol. 9, Part 1, of Ostwald-Drucker's Handbook of General Chemistry. R. Kremann & Robert Müller. Akademische Verlagsgesellschaft, Leipzig, 1930. Cloth 6¾ × 9½ inches, 891 pages. Price 85 RM.

This comprehensive reference book covers the theory of galvanic cells of all types and collects, in tables, about all the data available on the subject. It does not deal with fused salts, as electrolytes, but is complete as regards aqueous electrolytes and includes what data exist on alcohols, aniline and other organic electrolytes.

From the metallurgical point of view chief interest lies in the data on the potentials of various metals and alloys in various solutions, the discussion of the behavior of different types of alloy pairs from the equilibrium diagram point of view and the many points bearing on corrosion problems, such as the discussion of concentration cells, of oxidation and reduction phenomena, and all the factors affecting electrolytic attack and the precipitation of one metal by another out of solution.

The book is replete with references to the literature; the index covers 68 pages; the paper and printing are good, and the binding is solid enough to withstand the handling such a reference book will receive.—H. W. Gillett (0)-B-

Proceedings of the American Society for Testing Materials. Vol. 30, 1930, Part 1, Committee Reports and Tentative Standards, 1336 pages; Part 2, Technical Papers, 1085 pages. Each part $6.00 paper, $6.50 cloth, $8.00 half-leather.

All the reports and articles of metallurgical interest have been abstracted in *Metals & Alloys*. Besides the data on specifications and methods of testing, and the individual articles dealing with ferrous and non-ferrous alloys, several compilations containing vast amounts of data on special subjects make the volumes of distinct reference value. Among these may be cited in Part 1, the Report of the Research Committee on Fatigue of Metals, which summarizes present knowledge in that field, a new, extended and revised "Campbell's List of Alloys," and an extended tabulation of the compositions and properties of corrosion-resistant and heat-resistant alloys. In Part 2, a Symposium on Aircraft Materials, several articles on corrosion, and on fatigue, a summary on zinc-base die casting alloys and one on silver solders, are of especial value from the reference point of view.—H. W. Gillett (0)-B-

Advancement in Iron and Steel Metallurgy during 1929. H. M. Boylston (Case School of Applied Science). *Fuels & Furnaces*, Vol. 8, Jan. 1930, pages 23–36.

Review of progress made in ferrous metallurgy. Deals with development of stainless Fe and steel; dimensions and capacities of blast-furnaces; open-hearth furnace and practice; high-frequency induction furnaces; steel ingots; alloy steels; nature of martensite; constitutional diagrams; use of X-rays; heat treatment; and nitriding. MS(0)

Properties of Steel. *Iron & Coal Trades Review*, Vol. 121, July 4, 1930, page 13.

Abstract of a paper entitled, "Some Comments on Steel Specifications," read on May 9 by Dr. Johnston before the American Iron & Steel Institute at New York. See *Metals & Alloys*, Vol. 1, Oct. 1930, page 791. RHP(0)

Steel's Growing Service to Civilization. E. F. Kenney. (Bethlehem Steel Co.) *Heat Treating & Forging*, Vol. 16, March 1930, pages 348–351.

Paper read before the American Iron and Steel Institute. See *Metals & Alloys*, Vol. 1, Jan. 1930, page 336. MS(0)

Evaluation of Raw Materials for the Iron and Steel Industry. *Iron & Coal Trades Review*, Vol. 121, July 4, 1930, page 14.

Abstract of an article by Alfons Wagner published in *Stahl und Eisen*. See *Metals & Alloys*, Vol. 1, Aug. 1930, page 688. RHP(0)

Recent Developments in Nickel Iron and Steel. *Iron & Coal Trades Review*, Vol. 121, Aug. 15, 1930, page 227.

Abstract of article of same title by Charles McKnight read before the American Iron and Steel Institute in New York. See *Metals & Alloys*, Vol. 1, Aug. 1930 page 687. RHP(0)

Basic Principles of Theoretical and Applied Electrochemistry (Grundzüge der theoretischen und angewandten Elektrochemie). Georg Grube. Theodore Steinkopff, Dresden, 1930. Paper, 6¼ × 9 inches, 495 pages. Price 30 RM.

This second edition is a compilation of the former 2 volume edition into one volume. It is designed upon the basis of lectures at the Stuttgart Hochschule as an elementary treatise covering the theoretical foundation of electrochemistry of solutions, molten salts and gas reactions. A few classical examples serve to illustrate the presentation of Faraday's Laws as applicable to all electrolytic chemical phenomena. The modern theories of atomic structure and their relations to the ion, proton and electron are adequately developed and followed by an extended analysis of the theory of conductance which is generously assisted by the presentation of considerable data. The dissociation theory of strong and weak electrolytes from Arrhenius to DeBye is completely presented. The galvanic cell theory and experimental practice is well presented and followed by considerable data on activity coefficients. Complete discussion of the Lalande cell, the lead storage battery and the Edison cell is given. Although the author has prepared an elementary text, he is to be commended for the generosity shown in the variety of examples presented and the completeness of description of the technique of electrolysis. The application of electrolysis technique to oxidation and reduction is adequately presented. Metallurgists will be interested in the discussion of electrolysis of molten salts which leads to the derivation of alkali and alkaline earth metals, magnesium and aluminum. The commercial processes are described with unusual simplicity and directness. The discussion of electrothermic processes in the chemical and metallurgical industries is commendably introduced by an explanation of the Y and D circuits of 3 phase systems, direct and indirect resistance heating, indirect arc light heating, and combination arc light and resistance heating. Forty-three pages are devoted to the carbide industry and its various technical processes. The electrolytic preparation of phosphorus, zinc, pig iron and steel follow. The author gives many diagrams illustrative of the processes discussed which are well chosen for the simplicity with which they depict the fundamentals of the practice.—E. Seaton Carney (0)-B-

CORROSION, EROSION, OXIDATION, PASSIVITY & PROTECTION OF METALS & ALLOYS (4)

Letting the Specialist Prescribe Corrosion Remedies. *Chemical & Metallurgical Engineering*, Vol. 37, Aug. 1930, pages 488–489.

Outlines the research activities of the Duriron Company and gives examples of the service rendered by it in helping to solve the problems of different users of corrosion-resistant materials. MS(4)

Corrosion and Corrosion Protection on Rolled Aluminum Alloys in Aviation. (Korrosion und Korrosionschutz von Aluminium-Walzlegierungen im Flugzeugbau.) P. Brenner (Deutsche Versuchsanstalt für Luftfahrt). *Zeitschrift für Metallkunde*, Vol. 22, Oct. 1930, pages 348–356. Discussion.

Summarizes the main results of corrosion testing and outlines the influence of heat-treatment and cold work upon corrosion resistance of Duralumin and other Al alloys which can be age-hardened. The phenomenon of intercrystalline corrosion is dealt with at length. Stress is laid upon the new Duralumin ZB (L. Z. 127, Do X) which yields higher tensile strength, elongation and other physical properties without materially affecting the corrosion stability. This Duralumin is compared with the corresponding American alloy C 17 ST which, however, is higher in Si, artificially age-hardened and subject to intercrystalline corrosion. The second part of the lecture, delivered at the Corrosion Meeting of the Deutsche Gesellschaft für Metallkunde, is devoted to recent development of surface protection. The methods of Bengough, Gower, O'Brien, Jirotka, etc., on one hand and the Alclad, Allautal and Duralplat plating on the other hand are reviewed and a combination of the various protection methods suggested in conclusion. EF(4)

Application of Coatings on Steel Pipe to Prevent Corrosion. Russell W. Brandt (Youngstown Sheet and Tube Co.). *Metal Cleaning & Finishing*, Vol. 2, March 1930, pages 243–244, 247–248.

Transparent coating made up of china wood oil, linseed oil, or a mixture of the two together with a drier, are used to protect pipe in transportation or while in storage. Oils should be quick drying, and the films should be flexible and water resistant. The surface characteristics of the pipe control the non-volatile content of the oil. Pipe which has a fairly uniform film of scale does not require as heavy an oil coat as pipe which is entirely free from scale and has a very smooth bright steel surface. MS(4)

A Simple Method for Quantitative Observation of Atmospheric Corrosion in Protected Metallic Tubes. (Ein einfaches Verfahren zur quantitativen Verfolgung der atmosphärischen Korrosion geschützter Metallröhre.) W. Beck. *Korrosion und Metallschutz*, Vol. 6, Sept. 1930, pages 201–204.

Tubes of various ferrous materials, one half of which was protected by the "Schadebinde," were exposed to corrosion attack in moist air. The investigator kept track of the rusting process by means of the gas-volumetric method which mainly consists of the determination of oxygen in the surrounding atmosphere. In accordance with long time experiments in practice the accelerated tests yielded a remarkable protection against rusting and a preserved plasticity of the material tested. EF(4)

Experience with Aluminum Alloys in Sea Water. (Erfahrungen mit Aluminium-Legierungen im Seewasser.) H. Bauermeister. *Zeitschrift für Metallkunde*, Vol. 22, April 1930, pages 119–132. 8 references.

The paper presented before the Deutsche Gesellschaft für Metallkunde, Nov. 1929, summarizes the author's experience with Al alloys in continuous and intermittent contact with sea water. The observations are made on the following materials, the analyses of which are given: cast alloys of standard German and American composition, "Nitorit" pure Al casting, Silumin, KS-Seewasserlegierung, rolled alloys of pure Al KS-Seewasser plate, Silumin, Duralumin, Lautal, Aeron, Skleron and Constructal. The writer furthermore gives his experience with protective coatings of paint and metallic plating. Among casting alloys, the German and American alloy displayed satisfactory resistance to corrosion except when brass or bronze were in contact with the alloy tested or in its neighborhood. KS-Seewasser turned out very well and was superior even to pure Al. Various paints are recommended which, however, only inhibit corrosion and do not prevent it. According to the author, mechanical plating as "Duralplat" and "Allautal" is more promising. Includes discussion. EF(4)

Causes of Hydrodynamic Corrosion (Hydrodynamische Korrosionsursachen.) R. Auerbach. *AEG Mitteilungen, das Kraftwerk*, No. 1, Jan. 1931, pages 15–16.

If the flow of liquids in pipes is laminary at some places and turbulent (forming eddies) at others, electric potential differences are set up between these places. These potential differences can cause local corrosions. The author points out how the occurrence of such differences can take place in water-tube boilers and describes briefly a measuring arrangement in which a very sensitive galvanometer with 60,000 ohms/volt was used. Ha(4)

Fabrication of Acid-Resisting Steel. W. H. Hatfield. (Brown-Firth Research Laboratories.) *Heat Treating & Forging*, Vol. 16, May 1930, pages 621–624; June 1930, pages 755–758.

Heat and Corrosion Resisting Materials. H. D. Phillips (Empire Steel Castings Co.). *Heat Treating & Forging*, Vol. 16, April 1930, pages 466–470; *Blast Furnace & Steel Plant*, Vol. 48, July 1930, pages 1143–1147.

Review of the properties and principal applications from the point of view of heat and corrosion resistance of Al, Cu, Pb, Ni, Pt group, Ag, Sn, Zn, Nitralloy, cast-iron, and Cr, Cr-Ni, and high Si steels. MS(4)

Cadmium vs. Zinc Plating and the Status of Salt-Spray Corrosion Testing. H. W. Gillett. *Metals & Alloys*, Vol. 1, Aug. 1930, pages 667–671.

A correlated abstract. The discussion indicates evidence in favor of the higher merit of thin Zn plating over Cd for corrosion resistance. The salt spray test is considered as not suitable for general corrosion resistance testing. Correspondence from 16 authorities on the subject is published. ESC(4)

The Corrosion Resistance of Nickel. (Ueber die Korrosionsbeständigkeit des Nickels.) Rudolph Krulla. *Chemiker-Zeitung*, Vol. 54, June 4, 1930, pages 429–431.

The loss of weight of pure Ni through the attack of several acids and alkalies is illustrated with curves. Temperature and presence of air increase the rate of attack. Impurities in the solutions which form galvanic couples also increase the rate of attack. If the solution forms insoluble compounds with the metal these act as a protection. The addition of Cr and Mo raise the chemical resistance of Ni. K-25 containing 25% Cr and M-20 containing 20% Mo are commercial alloys. The latter is especially resistant to HCl. The use of Ni for cooking utensils is discussed. A loss in weight of 10 g./m.^{2}/day is not considered too high. Small % of Ni dissolved in foods are not harmful. CEM(4)

Calorizing Steel to Prevent Oxidation. *Machinery*, London, Vol. 36, June 5, 1930, pages 300–302.

In describing the methods of calorizing used by the Calorizing Company, Pittsburgh, Pa., consideration is given the application of calorizing to steel tubes; the construction of calorizing furnaces for revolving retorts; the time required for calorizing operation; and the dip calorizing process. (4)

Corrosion Testing of Electrodeposited Coatings. N. J. Gebert. *Metal Cleaning & Finishing*, Vol. 2, Jan. 1930, pages 33–36.

From paper read before the Philadelphia branch of the American Electroplaters' Society. Salt-spray method has been used for determining pinholes in Ni, Cu, and Cr deposits. This method has many disadvantages for routine production testing. 2 major objections are the uncertainty of the end-point, and the length of time required. A modification of the Blum and Thomas ferroxyl reagent has been found to give reliable and accurate information in 2 minutes. The solution consists of 15 g. agar, 6 g. $K_3Fe(CN)_6$, 60 g. NaCl, 1000 cc. distilled H_2O, and 250 cc. C_2H_5OH. The solution at 120° F. is sprayed on the bars by means of O. A blue spot shows a pinhole to the steel and a brown spot shows one to the Cu. If a bar shows more than the stipulated number of blue spots after 2 minutes, it is rejected. The bars must be thoroughly cleaned before applying the solution. A considerably stronger solution sprayed on paper is used for permanent test records. MS(4)

The Velocity of Dissolution of Non-Ferrous Metals as Dependent on Cold-Rolling. (Die Lösungsgeschwindigkeit von Nichteisenmetallen in Abhängigkeit vom Kaltwalzen.) B. Garre. *Korrosion und Metallschutz*, Vol. 6, Sept. 1930, pages 200–201.

In contrast with Heyn's statements the writer established that the dissolution speed of purest Sn (99.99%) decreases with increasing rates of deformation by rolling. Small impurities in Sn, however, result in a more pronounced dissolving of cold-rolled metal than encountered in the annealed material. The dissolving rate of lead and copper decreases with increasing rolling reductions. EF(4)

Corrosion Resistant Metals. H. A. De Fries. *Engineers & Engineering*, Vol. 47, Apr. 1930, pages 81–84.

Description of KA2, KA2-S, KA4 and NCT3. Considers the composition, heat-treatment and physical properties of principal Cr-Ni steels. The effects of components on welding, riveting and heating corrosion resistance are discussed. (4)

Corrosion Resistant Steels Solve Many Problems of Designers. H. A. De Fries. *Machine Design*, Vol. 2, May 1930, pages 23–25.

Notes on the uses of non-corrosive Cr and Cr-Ni alloys. Tables give analysis of KM-1 and KA-2 alloys. Data on heat treatment are given. (4)

Pitting in Water Turbines. Elov Englesson. *Engineer*, Vol. 150, Oct. 17, 1930, pages 418–421.

Gives brief description of phenomenon of cavitation. In 1912 view was expressed that pitting was caused by mechanical action rather than by corrosion. In making microscopic investigations of pitted turbine parts difficulties were encountered. Deformation of surface crystals occurs during grinding and polishing of sample piece. Impossible to determine if deformation is due to grinding or effect of water hammer. Erosion alone will produce pitting but corrosion plays a great part although its action is secondary. To avoid pitting attention should be given to design and arrangement of turbine since cavitation is origin of pitting. Tests were made to determine properties of material resistant to pitting by cavitation. Four blades were tested made of turbadium bronze, cast steel, stainless iron, and chromium plated cast steel. Turbadium bronze blade was badly attacked showing that propeller bronzes are not sufficiently resistant for water turbines. Cast steel blade was badly pitted also. After short time, plating wore off Cr-plated cast steel. The stainless iron blade showed high resistance to erosion. It is expensive and very difficult to machine so it is not very suitable for turbine material. LFM(4)

Action of Oxygen on the Corrosion of Iron and Steel in Aqueous Solutions. H. Endo & S. Kanazawa *Kinzoku no Kenkyu*, Nov. 1930, pages 605–614.

If a piece of Fe be dipped in water, a minute quantity of it passes into solution as ferrous ion; and the dissolution is accelerated by the formation of the concentration cell of the dissolved O. The authors named this the primary factor in the first stage of the corrosion of Fe. When the ferrous ion is formed and an equivalent H ion loses its electric charge, it is deposited on the surface of the metal, which has become cathodic, as a thin film of free H gas; and if O be introduced into the above system, the oxidation of ferrous hydroxide to hydrated ferric oxide, which is precipitated as rust, and the removal of the H film from the metal surface by oxidation may take place and, consequently, the corrosion of Fe is promoted by the action of O. The authors called this a secondary factor in the first stage of the corrosion. A $^1/_{10}$ g. mol. solution of KCl was filled in 2 glass bottles with an Fe test piece in each, and O was introduced in one bottle, then the larger the amount of O introduced, the quicker the Fe plate became cathodic. If O was introduced in 2 bottles alternately, one electrode changed its potential alternately, i. e., first from cathodic to anodic and next from anodic to cathodic. This is caused by the concentration difference of O in the bottles. If a test specimen was dipped in a still $^1/_{10}$ g. mol. solution of KCl, another in an agitated one, then the latter dissolved 5 to 6 times as much as the former. This was caused by the combined action of dissolved O and the continuous contact of fresh solution with the surface of the specimen. When H gas was blown in one of the bottles, the specimen was corroded only by $^1/_3$ that in the case of O. This is also caused by the action of dissolved oxygen as the secondary factor. When one side of the thin plate of Armco Fe was covered with paraffin and a half of another side by rust and dipped in $^1/_{10}$ g. mol. solution of NaCl, then the underlying portion near the uncoated part commences to suffer from anodic attack, giving iron chloride which tends to diffuse on the cathodic area of the uncoated part and iron hydroxide produced. After 2 weeks, ferric hydroxide was formed on the $^2/_3$ area of the uncoated surface and the $^1/_3$ part remained cathodic covered with a white membrane of ferrous hydroxide although some of it must be dissolved and oxidized in the solution, this region was proved to be alkaline by phenolphthalene. This part becomes cathodic and the part covered with rust anodic and thus the corrosion continues. KT(4)

Limitations of Cadmium and Zinc Coatings. Karl A. Eckhardt (Lamson & Sessions Co.). *American Machinist*, Vol. 73, Sept. 11, 1930, pages 429–432.

Salt spray tests do not check with natural weathering tests. Sherardizing fails in salt spray tests but will in some cases stand weathering. Cadmium and zinc are both good but often not for the same work. Describes and gives results of coatings given salt spray, and atmospheric test. Concludes that the salt spray test is unreliable. Sherardizing is superior for stove parts. Cadmium is useless in this field. RHP(4)

The Electrochemical Behavior of Metals. Joseph F. Chittum. *Journal of Physical Chemistry*, Vol. 34, Oct. 1930, pages 2267–2285.

The author presents a definition of passivity—a tendency on the part of iron to exhibit a potential lower than that of an iron amalgam under the same conditions, if the amalgam should behave similar to a sodium amalgam; iron is strongly passive when it fails to replace Cu^{++} from solution—and, after discussing current theories of corrosion and passivity, deals with experiments designed to validate the above definition. Explanations of passive iron and of the mechanism of corrosion in air, in the absence of oxygen and at a surface follow, these being based on an interpretation of the variation of the potential of metallic iron with the pH value of the solution in which the iron is dipped. STRUCTURE OF METALS & ALLOYS (5)

Metallography & Macrography (5a)

Plastic Deformation (Plastische Verformung). GEORG SACHS. **Testing and Examination of Metals and Alloys (Prüfung und Untersuchung der Metalle und Legierungen).** P. GOERENS & R. MAILÄNDER. **Handbuch der Experimentalphysik.** (Ed. by W. WIEN & F. HARMS.) Vol. V. Akademische Verlagsgesellschaft, m. b. H., Leipzig, 1930. Cloth, 6 3/4 × 9 1/2 inches, 656 pages. Price 66 RM.

This fifth volume of the proposed collection of 25 is actually 2 books in a single binding. The first, accounting for 134 pages, deals in part one with crystals and their properties and in part two with the working of crystalline aggregates. In the former, methods for the preparation of single crystals of metals are described, these being followed by a discussion of the determination of orientation, the mechanism of the movement of crystalline units under stress, hardening due to cold working, recrystallization, internal stresses, effects of deformation upon elastic properties, dependence of these effects upon the temperature of deformation, and finally the fundamental information obtained from mechanical tests of single crystals. Then, with the aid of a few carefully chosen macrographs, micrographs, Laue X-ray patterns and diagrammatic records the author deals briefly but effectively with polycrystalline bodies. There are covered in turn the influence of working and recrystallization upon orientation, grain size and flow lines, internal effects due to external stress application and their identification by the resultant changes in elastic properties and X-ray behavior, hardening and softening phenomena and their theoretical explanation and finally a simple mathematical analysis of deformation due to contraction in tension testing, indentation in hardness testing and compression and elongation in rolling and drawing. The entire treatment is concise but most complete, one finding references to practically every important investigation bearing upon the author's subject.

The second "book" is divided into 3 parts. In the first, Dr. Mailänder describes the equipment and methods for the determination of the mechanical properties of metallic bodies. Although carefully describing the loading mechanisms and the measuring devices, more attention is devoted to the principles underlying them, the influence of the variables of the testing procedure and the data resulting from the examination of typical materials. Were it not for a noticeable lack of references to other than German publications in all except the description of endurance testing and the omission of several important devices developed in other countries and widely used, this section might be considered most complete for its length (350 pages) including, as it does, practically every form of mechanical testing even to determination of wear resistance, internal stresses, etc. An interesting section is devoted to stress distribution and determination in bodies of other than simple form. Occasionally, however, such as in bend-testing and wear-testing, the treatment is conservative and the most recent developments are absent (except in endurance testing references as late as 1928 are scanty).

In the second part, also by Dr. Mailänder, the study of physical properties is considered, specific weight, electrical conductivity, the magnetic characteristics, thermal expansion, thermal conductivity, specific heat and the detection of defects by radiography. Again, there is the almost exclusive reference to German publications and apparatus but here, likewise, frequent use of typical data gives the discussions a sense of completeness.

The third part by Prof. Goerens is devoted to thermal properties and metallographic characteristics. There are included examples of the thermal, dilatometric, magnetic, electrical, thermo-electric and metallographic methods for the determination of equilibrium diagrams; also, the macro- and micro-structural features appearing in metals due to their thermal and mechanical history as well as the methods used to reveal them. In the entire volume only this part suffers unduly from brevity (70 pages) and leaves the reader without much necessary information and a strong desire for more details.

The appearance of the volume is highly commendable; it is replete with excellent diagrammatic illustrations and remarkably free from uninformative photographs.—Jerome Strauss (5a)-B-

Problems of the Metallic State. (Probleme des Metallischen Zustandes.) J. D. BERNAL. *Metallwirtschaft*, Vol. 9, Nov. 28, 1930, pages 983–987.

A theoretical discussion containing 14 references. An attempt is made to find a relationship between the structural crystallography of metals and intermetallic compounds and their theoretical physical basis, with special regard to the recent studies of Slater. The nature of the different forces of attraction between atoms, metals and intermetallic compounds is pictured qualitatively, and thus a foundation is laid for their classification and an explanation of their physical and chemical properties is given. The 2 principal forces assumed are: (1) the Coulomb force of attraction between electron orbits of adjacent atoms which overlap each other; and (2) those according to Heitler and London, which are equivalent to a generalized chemical co-valence. The metals and their compounds are roughly classified according to the relative prevalence of these forces. The crystalline structure of intermetallic compounds is discussed and coördinated with their physical, magnetic and electrical properties. The chemical composition of these compounds and their laws, such as the Hume-Rotherys law, are explained. The present unsatisfactory status of our knowledge regarding solid solutions is discussed. CEM(5a)

Phase Changes in Iron-Silicon Alloys. BRADLEY STOUGHTON & E. G. GREINER. *Fuels & Furnaces*, Vol. 8, July 1930, pages 927–930.

From paper read before the American Institute of Mining & Metallurgical Engineers. See *Metals & Alloys*, Vol. 1, June 1930, page 564. MS(5a)

Plastic Areas in Structural Sections. ROBERT L. GERUSO. *Heat Treating & Forging*, Vol. 16, May 1930, pages 618–620.

Used a modified Fry macro-etching reagent to reveal strained areas caused by shearing, punching, sawing, and welding. Modification consists in the use of 3 1/3 grams less $CuCl_2$/100 cc. H_2O. Etching was improved by agitating the solution and maintaining it at a temperature of about 350° C. Presents illustrations showing areas plastically deformed by the various operations. MS(5a)

New Etching Reagent for the Macrography of Aluminum and Its Alloys. C. M. TUCKER. *Metals & Alloys*, Vol. 1, Aug. 1930, pages 655–656.

45% HCl Sp. Gr. 1.18, 15% HNO_3 Sp. Gr. 1.42 ,15% HF Sp. Gr. 1.15, and warm water yield a reagent suitable for etching Al and its alloys. Surface should be cleaned with carbon tetrachloride and swabbed while treated to prevent film which reduces cleanliness and contrast of the etch. ESC(5a)

A Study of the Relation between Macro- and Microstructure in Some Non-Ferrous Alloys. M. L. V. GAYLER. *Engineering*, Vol. 130, Sept. 19, 1930, pages 380–382. Discussion, page 358.

Condensed from paper read before the Institute of Metals, Sept. 10, 1930. See *Metals & Alloys*, Vol. 1, Nov. 1930, page 844. LFM(5a)

A Note on the Constitution of Cadmium-Zinc Alloys. D. STOCKDALE. *Engineering*, Vol. 130, Sept. 26, 1930, page 389.

Abstract of paper read before the Institute of Metals, Southampton, Sept. 11, 1930. See *Metals & Alloys*, Vol. 1, Nov. 1930, page 844. LFM(5a)

Determination of Sulphur in Steel. (Zur Frage über den Nachweis von Schwefel in Stahl.) P. SACHAROFF & PH. RYBINSKY. *Stahl und Eisen*, Vol. 50, Nov. 6, 1930, pages 1587–1589.

After reviewing the literature on the detection of S in steels, the authors give their own results in examining the S segregations in rails. The Baumann method was found most suitable for this purpose. P has no remarkable influence on the Baumann test. It is shown that by standardizing the specifications of the Baumann test it will be possible to make the Baumann test a quantitative indicator of the amount of S present as illustrated in S prints attached. GN(5a)

Metallography of Screw Stock. (Metallographisches über Automatenstähle.) H. RUDOLPH. *Mitteilungen aus den Forschungsanstalten des G.-H.-H.-Konzerns*, Vol. 1, Nov. 1930, pages 25–32.

Discussion of S and P in screw stock. Ordinary steels with only a quarter of the S and P found in screw stock may show segregation so great that the ocal concentration of these elements is as great as in the screw stock. Inclusions in ordinary steel may be as harmful as the MnS inclusions in screw stock. In view of the better machinability, screw stock has a wider range of usefulness than is ordinarily considered. HWG(5a)

A Furnace for Metallographic Examination of Specimens at High Temperatures. B. A. ROGERS. *Metals & Alloys*, Vol. 2, Jan. 1931, pages 9–12.

A furnace is described for heating specimens under microscopical observation. Experiments show that it is possible to observe marked surface changes upon some elements as these pass through certain allotropic transformations presumably connected with a shift of space lattice. These transformations can be traced at least when considerable percentages of other metals have been added. Observations at a magnitude of 50 to 75 diameters can be conducted on samples heated to above 1500° C. and at higher magnifications when the temperature does not exceed 1000° C. Photographs of which several have been included with this paper, can be taken at magnifications of about 150 diameters for temperatures up to 1000° C. and presumably at lower magnifications for higher temperatures. Observations have been made under these conditions upon Fe, Co, and Mn. ESC(5a)

Changes in the Composition of Cementite during the Drawing of Special Steels. (Changement decomposition du constituent cémentite au cours du revenu des aciers speciaux.) A. PORTEVIN & P. CHEVENARD. *Comptes Rendus*, Vol. 191, Sept. 1, 1930, pages 408–411.

Authors describe the results of experiments with a hyper-eutectoid Mn steel (1.5% C, 2% Mn) designed to show how the alloying element (in this case Mn) in such a steel distributes itself between the phases ferrite and cementite during treatment. They find that below 200° C., drawing causes the precipitation of a carbide having a Curie point at 120° C., the Fe remaining in the γ-state. The γ-α transformation occurs between 200° and 225° C., this change being practically complete at 260° C. The carbide precipitated during the γ-α transformation is, however, distinct from that liberated below 200° C. Its Curie point is 50° C. higher; it is, therefore, poorer in Mn. After drawing at temperatures in excess of 260° C., a portion of the C passes into solid solution—as the Fe is in the α-state the reaction *austenite* ⟶ *aggregate of martensite + cementite* must be assumed. Increasing drawing temperatures result in a decrease in the C content of the martensite. After drawing at 400° C. the steel is in the sorbitic state—*aggregate of carbide + ferrite almost free from C.* At temperatures above 400° C., the carbide precipitated during drawing reacts with the ferrite and enriches itself with Mn at its expense. This lowers the Curie point of the carbide again. OWE(5a)

The Influence of Reduction, Rolling Temperature, Cooling Conditions and the Mechanical Properties on the Structure of Low Carbon Steel. (Ueber den Einfluss des Walzgrades, der Walz-temperatur und der Abkühlungsbedingungen auf die mechanischen Eigenschaften und das Gefüge von kohlenstoffarmen Flussstahl.) A. POMP & E. FANGMEIER. *Mitteilungen Kaiser Wilhelm Institut für Eisenforschung*, Vol. 12, No. 15, Report 159, pages 245–262; *Stahl und Eisen*, Vol. 50, Dec. 4, 1930, pages 1721–1723.

Low carbon flats (0.08% C) of 32 to 34 mm. width and various thicknesses were rolled in one reduction each to the same size of 20 mm. thickness and cooled either rather rapidly on a 10 mm. thick cast iron plate or relatively slowly in kieselguhr. The following table contains the treatment of the 2 groups tested:

Treatment of Steel Tested

Height before rolling mm.	Height after rolling mm.	Reduction mm.	Reduction %	Rolling temperature ° C.	Cooling conditions
			Group I		
30	20	10	33	700	Cooling on plate and Kieselguhr
28	20	8	29	800	
26	20	6	23	900	
24	20	4	17	1000	
22	20	2	9	1100	
				1200	
			Group II		
20	10	10	50	700	
18	10	8	44	800	
16	10	6	37	900	
14	10	4	29	1000	
12	10	2	17	1100	
				1200	

The tensile strength, yield point, elongation, hardness, notch toughness and the grain size were determined. The most favorable physical properties are obtained in both groups at rolling temperatures between 900° and 1000° C. At this rolling temperature, the values of normalized steel are at least reached if not surpassed. Indications of strain hardening appear in rolling at 700° C. Tensile strength, yield point, and hardness increase; elongation, reduction of area, notch toughness and grain size decrease. In rolling between 700° and 900° C., the tensile strength, yield point, hardness and, particularly, the notch toughness decrease due to the coarse grain recrystallization. This holds especially for the slowly cooled samples. At rolling temperatures above, the effects of superheating with its impairing influence on the properties are observable. GN(5a)

The Nature of Hardness. (Ueber die Natur der Festigkeit.) M. POLANYI. *Mitteilungen der deutschen Materialprüfungsanstalten*, Sonderheft 13, 1930, pages 113–119.

Philosophical discussion of why a metal is hard. Illustrated by diagrams showing irregular atom distribution in gases, amorphous bodies and oriented arrangement in crystals, lattice structure in single crystals and polycrystalline materials, slip in single and poly-crystals, and distortion of the lattice on bending. Crystalline materials may allow themselves to be plastically deformed so that the most closely packed atom rows glide into positions so that these rows are parallel. At very low temperatures, amorphous bodies are completely brittle, while crystalline ones are not much less ductile than at ordinary temperatures. To produce plasticity, the still generally valid orderly arrangement of the atoms in the crystal must be somewhat disturbed. A distorted crystal has a mixed crystalline and amorphous character. (5a)

PHYSICAL, MECHANICAL & MAGNETIC TESTING (6)

The Magnetic Properties of Permalloy with Internal Stresses and Their Influencing by Exterior Tension and Compression. (Ueber die magnetischen Eigenschaften von Permalloy mit inneren Spannungen und ihre Beeinflussung durch äusseren Zug und Druck.) OTTO VON AUWERS. *Wissenschaftliche Veröffentlichungen aus dem Siemens-Konzern*, Vol. 9, No. 2, 1930, pages 263–293.

The extraordinary sensitiveness of Permalloy to mechanical forces has long been recognized; longitudinal tensile stresses increase the permeability enormously while bending stresses destroy those excellent magnetic properties if they disturb the lattice structure. On account of the great importance of this material in telephony and telegraphy the interdependence between magnetic properties and mechanical forces has been further investigated in the present work with regard to (1) influence of internal stresses in the material; (2) influence of longitudinal tensile stresses; (3) influence of hydraulic pressure. These influences were studied on covered wires, that is wires of permalloy which have a core of another alloy. By suitable thermal treatment inner stresses could be produced at will. The influences of tension and compression were examined for the original curve, μ-curve, maximum permeability, remanence, coercive force, and position of hysteresis loop. For the latter it is shown that the loops are tilted under the action of tensile stress about a fixed axis passing through the zero point so that there exist 2 fixed points on the increasing and decreasing branches, the coördinates of which are independent of the load. Compression acts essentially only on the coercive force but in an opposite sense as tension. Eighty six figures and 20 bibliographical references supplement this very exhaustive investigation. Ha(6)

Fatigue Stresses with Special Reference to the Breakage of Rolls. F. BACON (Univ. College, Swansea). Advance copy for Nov. 18, 1930 meeting South Wales Institute of Engineers, 112 pages.

Starting from the observation that the fractures of chilled Fe rolls are characteristic fatigue failures, Bacon examines the relation of fatigue properties to roll service. Available data indicate that the endurance limit for the gray Fe core of a good roll should be about 11,000 lbs./in.^{2} just below the mottle. No good estimates are available on the endurance limit of the mottle itself, nor on that of the chill. As a purely tentative figure it is thought that the chill might show an endurance limit of 18,000 lbs./in.^{2} From such data as are available, it would appear that the endurance limit of gray Fe at the working temperature of the rolls will not be less than at room temperature, but nothing is known of the properties of chilled and mottled Fe at elevated temperatures. Broken rolls show heat-tinted cracks. Mathematical studies indicate that the fatigue stresses in uncracked rolls may not usually exceed the endurance limit. But if surface hair cracks form, the repeated stresses may very readily propagate the cracks, especially if the cracks penetrate below a given depth. This critical depth, found by mathematical study, coincides with the depth of chill preferred in service, i. e., about 0.035 times the diameter of the roll. The idea is advanced that surface cracks readily propagate between the columnar crystals of the chilled layer and tend to stop at the mottle, unless the stress at that point is high enough to make them continue to propagate. Failure by crack-continuation is then an important concept and the resistance of the Fe in the roll, not only to the formation, but also to the propagation of a crack, needs attention. If a new roll is severely overloaded it will break in a few revolutions at a surface stress well below its static modulus of rupture. It is suggested that a study of some method of evaluating the "running modulus of rupture" as well as the determination of the endurance limit of chilled and mottled Fe would be of value in the effort to choose a metal that will best resist roll failure. The combined torque and rotary bending stresses in the bottom roll are examined mathematically. Similar study of top rolls leads to the conclusion that on the basis of the theory of failure by fatigue, the top and bottom rolls should be equally likely to break. This is borne out in practice. Work done by Dr. F. Rogers in 1905 is referred to, in which the formation of incipient cracks in a fatigue specimen was studied by heating under oxidizing conditions so that cracks already formed became heat-tinted. The specimen was then re-run to failure. The life in the second stage (all tests, on a 0.27% C, 1% Mn steel being made at the same stress, 50,000 lbs./in.^{2}) was proportional to the extent of the heat-tinted cracks. Analogous temper colors are found on rolls fractured in service. Mathematic analysis is made of the stresses in rotating beams of lenticular section, with part of the cross section broken through by the advance of a progressing fatigue failure. The hair crack marks on the fatigue fractures of shafts, rolls, etc., are generally, in unflawed material, simple geometrical curves. From his analysis, Bacon concludes that the roots of fatigue cracks in rotating beams tend to lie on surfaces of uniform crest stress ratio. HWG(6)

Fatigue Strength of Nitrided Steels. (Biegeschwingungsfestigkeit von nitrierten Stählen.) O. HENGSTENBERG & R. MAILÄNDER. *Krupp'sche Monatshefte*, Vol. 11, Sept.-Oct. 1930, pages 252–254.

Endurance bending tests were performed on 6 different steels after they had been subjected to 3 different treatments: (a) quenched and drawn, (b) quenched and drawn and finally tempered at 500° C. for 48 hrs., (c) quenched and drawn and nitrided at 500° C. for 48 hrs. The table below gives the composition and treatment:

Symbol of	Chemical Composition							Heat Treatment	
Steel	C	Si	Mn	Cr	Al	Ni	Mo	Quench	Draw
FP 15	0.3	.43	.41	1.43	1.12	..	..	920° C. oil,	650° C. air
FP 13	0.52	.14	.27	1.74	1.28	..	..	900° C. oil,	650° C. air
FP13A	0.52	.14	.27	1.74	1.28	..	..	880° C. oil,	670° C. air
FPK 13	0.32	.22	.72	1.24	.93	..	0.34	840° C. water,	600° C. air
FPE 23	0.42	.19	.38	1.68	1.33	2.65		870° C. oil,	660° C. air
FK 345	0.15	.25	.4	.85	..	..	0.41	930° C. oil,	650° C. air

The nitrided samples show an essential increase of the endurance bending strength as determined with machine developed by C. Schenck, Darmstadt, Germany. The results are as given in the following table:

Symbol of Steel	Heat Treatment	Endurance Bending Strength
FP 15	a	42 kg./mm.^{2}
	b	40–41 kg./mm.^{2}
	c	55 kg./mm.^{2}
FP 13	a	50–51 kg./mm.^{2}
	b	52 kg./mm.^{2}
	c	67 kg./mm.^{2}
FP 13 A	a	46–47 kg./mm.^{2}
	c	59 kg./mm.^{2}
FPK 13	a	48–49 kg./mm.^{2}
	c	62–63 kg./mm.^{2}
FPE 23	a	55 kg./mm.^{2}
	c	68 kg./mm.^{2}
FK 345	a	43 kg./mm.^{2}
	b	46–47 kg./mm.^{2}
	c	67–68 kg./mm.^{2}

The increase of the endurance bending strength of the nitrided sample does not only depend on the composition of the steel but also on the thickness of the nitrided skin in relation to the core. Small surface faults of the nitrided specimens have no influence on the endurance bending strength. GN(6)

Effect of Section Size on Physical Properties of Cast Iron. A. L. BOEGEHOLD. *Proceedings American Society Testing Materials*, Vol. 30, Part 1, 1930, pages 199–205.

Includes discussion. See *Metals & Alloys*, Vol. 1, Nov. 1930, page 846. (9)

The Cupping Test for Aluminum Sheet. ROBERT J. ANDERSON. *Metal Industry*, London, Vol. 37, Sept. 19, 1930, pages 265–268.

As measure of drawability, the most reliable and most practical and simple test is the cupping test, such as is made on Olsen ductility or Erichsen indentation machines. Describes the apparatus and method of testing. Actual values for Al sheets depend upon temper of sheet, its thickness, composition, grain size and general quality. Contains a number of tables giving cupping values for sheets of various gages. VSP(6)

The Nature of Remanence and the Losses by Hysteresis. (Ueber die Natur der Remanenz und der Hysteresisverluste.) N. S. AUKLOV. *Zeitschrift für Physik*, Vol. 64, Sept. 22, 1930, pages 817–829.

It is shown theoretically that single ferromagnetic crystals do not possess remanence nor losses due to hysteresis. These are only found in polycrystalline aggregates with internal strain. To obtain, therefore, a ferromagnetic alloy with low hysteresis losses the internal strain must be small and the single crystals of the alloy should not possess magnetostriction. The magnetic properties of permalloy and perminvar are discussed. (6)

How Designers Can Appraise Metals from Hardness Test Data. E. S. AULT. *Machine Design*, Vol. 2, Feb. 1930, pages 35–38.

A statement of the fundamentals of hardness testing and a classification of purposes. Rockwell, Brinell and Vickers testing machines are described. (6)

Significance and Evaluation of Fracture Elongation of Metals. (Zur Deutung und Bewertung der Bruchdehnung bei Metallen.) W. KUNTZE. *Mitteilungen der deutschen Materialprüfungsanstalten*, Vol. 14, 1930, pages 61–71.

See *Metals & Alloys*, Vol. 1, Oct. 1930, page 796. (6)

Notched-Bar Impact Tests—Standard Test Piece. (Kerbschlagproben—Normenprobe.) R. PAWLISKA & M. SCHMIDT (Gebr. Böhler & Co., Austria). *First Communications of the New International Association for the Testing of Materials*, Group A, Zurich, 1930, pages 217–221.

The variables in impact testing are briefly discussed. A square Charpy bar with 45° notch with 0.25 mm. root radius is favored. HWG(6)

Comparative Investigations of Rails with Water-Hardened Surface. (Vergleichende Versuche an Schienen mit wassergehärteter Lauffläche.) O. PILZ & H. MEYER. *Stahl und Eisen*, Vol. 50, Nov. 6, 1930, pages 1557–1566.

In referring to the failure of rails, the literature on this subject is dealt with showing that among the rails with an increased resistance to wear, those with a not too-pronounced hardness of the surface are supposed to be most suitable due to the high toughness which decreases cracks. Transverse cracks are probably not a primary cause of failures. Shatter cracks have not yet been found in Thomas steel. The origin of shatter cracks is discussed. In order to determine the influence of a very hard surface, rails which have been surface hardened by various methods have been tested by the authors. The one group of rails tested was manufactured by the French company, Compagnie des Forges de Chatillon, Neuve Maisons; the other group was a product of the German Maxhütte, Rosenberg, Bavaria. The composition, structure, conditions of segregations, distribution of the hardness along the surface, the results of tensile tests and impact tests, of notch toughness tests and endurance impact tests as well as the wear resisting properties are given. The Maxhütte rails with a harder surface gave better wear resisting properties and more favorable results in practical application. GN(6)

Cast Iron Testing in Great Britain. J. G. PEARCE (British Cast Iron Research Association). *First Communications of the New International Association for the Testing of Materials*, Group A, Zurich, 1930, pages 1–4.

Discusses consideration leading to adoption of standard transverse bars cast separately: S—0.975″ diameter, 15″ long, 12″ centers, to represent castings under ¾″ thickness; M—1.2″ diameter, 21″ long, 18″ centers, to represent castings ¾″ to 2″; L—2.2″ diameter, 21″ long, 18″ centers, to represent castings over 2″. Tensile bars from these are machined to S, 0.564″; M, 0.798″; L, 1.785″ diameter at the breaking section. HWG(6)

The Testing of Cast Iron. (Die Prüfung von Gusseisen.) E. PIWOWARSKY (Technische Hochschule, Aachen). *First Communications of the New International Association for the Testing of Materials*, Group A, Zurich, 1930, pages 5–9.

List of tests used in Germany. Description of each extremely brief. Shear tests show no satisfactory relation to tensile tests. (6)

Electromagnetic Method for Testing Large Rotors for Hidden Defects of Manufacture. (Elektromagnetisches Verfahren zur Prüfung grosser Induktorkörper auf verborgene Herstellungsfehler.) R. POHL. *Forschung und Technik*, 1930, pages 455–468.

A method is described by which hidden defects in large cylindrical forged pieces with an axial bore can be detected. A current of from 1000 to 2000 amperes is sent from one side of the piece such, as a big shaft, to the other side diametrically across from it so that it flows to both sides of the bore. If a coil is placed in the latter and the current broken or reversed, the coil which is connected to a very sensitive mirror galvanometer will be subject to a magnetic field should a magnetic asymmetry be present due to defects. The method is theoretically discussed and instruments described, as well as test results on a shaft of 5280 mm. length, 495 mm. diameter and 69.5 mm. bore. The sensitivity of the method is very great and is little influenced by exterior disturbances. Some suggestions are added to make this method still more convenient for practical application. Ha(6)

A New Testing Apparatus for Deep-Drawing Sheet. (Ein neues Prüfgerat für Tiefziehbleche.) G. SACHS. *Mitteilungen der deutschen Materialprüfungsanstalten*, Sonderheft 13, 1930, pages 80–85.

See *Metals & Alloys*, Vol. 1, Nov. 1930, page 847. (6)

Mass Testing of Workpieces with the Rockwell Hardness Tester. (Massenkrontrolle von Werkstücken.) A. RUETER. *Maschinenbau*, Vol. 8, Dec. 5, 1929, pages 790–794.

The Rockwell hardness tester, its performance and operation, is described. On the basis of actual experience, the use of the instrument for mass testing is outlined and the influences leading to deviating indications are investigated. By means of frequency curves, tolerances for test pieces are determined. (6)

Relationship between Rockwell and Brinell Numbers. S. N. PETRENKO. *Metals & Alloys*, Oct. 1930, pages 782–787.

An extended abstract. See *Metals & Alloys*, Vol. 1, Nov. 1930, page 847. ESC(6)

ELECTRO-CHEMISTRY (7)

Electroplating (7a)

The Technique of Electro-Deposition (Galvano-Technik, Galvanostegie und Galvanoplatik). H. KRAUSE. Max Jänecke Verlagsbuchhandlung, Leipzig, 1931. Paper, 6 × 8 1/4 inches, 272 pages. Price 5.40 RM.

This edition resembles previous editions, but is brought more nearly up to date, and contains a little new matter on plating masses of objects in drums, and an index, lacking in previous editions.

The theory of electroplating is briefly discussed, and directions given for plating Ni, Co, Cr, Fe, Zn, Cd, Sn, Pb, Cu, brass, Ag, Au, Pt and Pd. In most cases, mention is made of a considerable number of baths suggested by various authorities without giving sufficient critical discussion to tell the reader what their advantages and disadvantages are. When information in periodical literature is cited, the names of the authors are given, but not the journal reference. Hence, the reader will find it difficult to look up the original literature.

The paper and printing are good.—H. W. Gillett (7a)-B-

Nickel Anodes. G. W. PAWEL & G. B. HOGABOOM. *Metal Industry*, N. Y., Vol. 27, June 1929, page 288.

The importance of a more comprehensive knowledge of the factors governing the successful deposition of nickel from high purity anodes is emphasized in correspondence arising out of a recent paper on the influence of certain addition agents to nickel-plating solutions. It is pointed out that anodes which are of high quality and capable of producing an excellent quality of plate are being used in a number of cases under conditions which make it impossible to obtain satisfactory results. The anode, though of primary importance, is only one factor in the situation, and while it is admitted that still further work is needed on the production of an anode which will corrode evenly and without excessive sludging, it is urged that much also remains to be done along the lines of adjustment of composition of the solutions used, and the control of their acidity. (7a)

Nickel Plating of Small Aluminum Parts. ANDREW V. RE. *Metal Cleaning & Finishing*, Vol. 2, April 1930, pages 323–324, 344.

Gives solution formula and procedure to follow in cleaning, acid dipping, brass plating, Ni plating, and buffing. MS(7a)

Chromium Plating. E. W. DOBBS. *Metal Industry*, London, Vol. 36, Feb. 7, 1930, page 168.

Abstract of paper read before the Birmingham and Midlands local section of the Society of Chemical Industry. VSP(7a)

Mass Production Methods in Depositing Nickel at High Current Density. N. R. LABAN. *Metal Industry*, London, Vol. 36, June 13, 1930, pages 629–630; June 27, 1930, pages 674–676; Vol. 37, July 11, 1930, pages 39–40.

Includes discussion. From paper presented before the Electroplaters' and Depositors' Technical Society. Describes methods which have proved satisfactory over a period of several years for the deposition of Ni. Methods are particularly suitable when Ni is used as basis for Cr. Current densities between 60 and 100 amp./ft.^{2} are practical for the majority of components used in motor and cycle work. Advantages in use of high C. D. are not confined to output. Deposits obtained have excellent mechanical properties, well suited to engineering purposes. VSP(7a)

METALLIC COATINGS OTHER THAN ELECTROPLATING (8)

Hot Galvanizing (La galvanisation a chaud). M. C. KLUYTMANS. Bibliothique de L'Usine, Paris, 1927. Paper, 6 × 9 1/4 inches, 86 pages. Price 18.80 Fr.

Brief generalities on hand and mechanical galvanizing, covering about what might be expected in a pamphlet of this sort, if one doesn't expect any real metallurgical information. As samples of the type of information, we cite the following: The lower part of the pot is customarily spherical or flat, and its form is oval or rectangular. . . .The melting point of zinc is +12° C. (doubtless poor proof-reading for 412°, itself incorrect for pure zinc, with no explanation given that it refers to impure zinc). . . .The workmen at the pickling baths should be given strict orders to drink their quart of milk per day, to eliminate the irritation due to acid vapors. . . .

The author's conclusions are, that in spite of all the literature on galvanizing, practice will teach more than books, and that one can read and re-read the treatises, but if he has not breathed the acid fumes, etc., he will have to pass through these discomforts to get results.

In respect to any help to be gotten from this particular book, the author seems to have appraised the situation correctly.—H. W. Gillett (8)-B-

Hot Galvanizing as It Affects Mild Steel. J. C. ALLAN & R. L. GERUSO. *Heat Treating & Forging*, Vol. 16, Jan. 1930, pages 70–75.

Investigation of the effect of galvanizing on the physical properties of cold-worked bolt steels. Steel used contained 0.22% C, 0.89% Mn, 0.14% P and 0.034% S. It was annealed at 840° C. for 1 hr. and then cold worked 4, 8, 12, 16, and 20% by elongation in an Olsen tension machine on standard A.S.T.M. test specimens 4 in. long. Bending and notched-bar impact specimens were shaped from these elongated specimens. Every specimen was pickled in warm H_2SO_4 prior to galvanizing at 440° C. Results of tests show that galvanizing raises the yield-point and tensile strength of steel cold worked from 0–20%. The increased values, however, are not much different from those obtained when such steel is cold worked 0–20% and then subjected to simple annealing at 440° C. The ductility, as measured by elongation, closely approximated the values obtained when cold-worked steel is annealed 440° C. Notched-bar impact resistance of steel cold worked 0–20% is decidedly lowered by galvanizing. This galvanized steel when sorbitized, has an Izod notched-bar impact resistance of approximately 45 ft.-lbs. Galvanized sorbitic steel and steel cold worked 10–16% prior to annealing at 440° C. have approximately the same resistance. Galvanized overstrained steel is very brittle. In the bending test, cracks became very visible with steel overstrained 12%. Includes illustrations of strain lines in bolts during various stages of manufacture and photomicrographs of faulty galvanized bolts. It is concluded that cold-worked steel should be thoroughly annealed before galvanizing, particularly if the steel is deformed 12–16%. Any unnecessary surface irregularities should be avoided in preparing material for hot galvanizing. MS(8)

Metal Spraying. S. H. GRIFFITHS. *Proceedings Staffordshire Iron & Steel Institute*, Vol. 45, 1929–30, pages 60–65.

Elementary description of the metal spray process. Particles produced by the spray should be of about the same size as the cavities formed on the surface to be coated by the preliminary sand blasting. Porosity of the deposits is remedied by treatment with a "special chemical dope" (apparently of the type of Bakelite varnish) or by a type of burnishing operation that causes the metal to flow. Zinc coatings are the ones more readily applied. Other sprayed metals will cling well to a sprayed zinc surface. Sprayed aluminum coatings for grate bars, annealing boxes, etc., are best applied on cast iron of low silicon content as that is less liable to growth and consequent cracking of the coating. (8)

INDUSTRIAL USES & APPLICATIONS (9)

Tubes for High-Pressure Water-Tube Boilers. S. F. DOREY. *Engineer*, Vol. 150, Nov. 21, 1930, pages 566–568; Nov. 28, 1930, pages 589–591. Discussion pages 572–573, 600–603.

Condensed from paper read before the Institute of Marine Engineers, Nov. 11. See also editorial comment on pages 599–600. LFM(9)

Steels in Marine Engineering and Shipbuilding. J. W. DONALDSON. *Metallurgia*, Vol. 3, Dec. 1930, pages 41–45.

Discusses use of carbon and alloy steels in shipbuilding, boilers, turbines, oil engines, and gears. Predicts an extended replacement of carbon steels and non-ferrous alloys by alloy steels. JLG(9)

Welding Processes Used in Making Planes. J. B. JOHNSON. *Welding*, Vol. 1, Sept. 1930, pages 735–738.

The following types of welding have been used extensively enough in the aircraft industry to be called production processes: (1) gas welding (oxy-acetylene and oxy-hydrogen); (2) electric arc welding (a. c. and d. c.); (3) electric resistance welding (flash welding and spot welding). Electric butt welding and the Hyde process of copper welding are used to a limited extent. Oxy-acetylene welding is used for fabricating some part of the airplane structure and in many plants for all ferrous metal joints in the fuselage, wings and landing gears. Oxy-hydrogen welding is used extensively for welding aluminum. Electric arc welding has been used for joining carbon and alloy steel parts but not for non-ferrous metals; it can be used successfully on material 0.031 in. or more thick. D. c. machines give better results than a. c. Arc welding is not suitable for close fitting parts. Flash weld is limited to pieces of the same cross section. The application of spot welding to austenitic steels has been more successful than in pearlitic structural steels. W(9)

Applications of the Welding Processes on the Boston and Maine. Part II. M. A. THOMPSON. *Welding*, Vol. 1, Jan. 1930, pages 168–170.

Cost figures for gas welding cylinders, frames and miscellaneous repair jobs, showing saving effected. W(9)

Production and Thermal Treatment of Sheets for Automotive Industry. (La fabrication et les traitements thermiques de la tole pour l'industrie automobile.) A. T. KATHNER & P. DAMIRON. *Revue de Metallurgie*, Vol. 27, Nov. 1930, pages 615–629.

A rather detailed survey of the demands made on different types of sheets in the automobile industry, their manufacture and heat treatment. The article is based on U. S. practice and deals both with physical and microscopic testing and all phases of the manufacture are briefly touched, special attention being given to heat treatment. 15 microphotographs and 14 references are given. JDG(9)

Stainless Steel Replaces Plated Parts. 1930. *Heat Treating & Forging*, Vol. 16, April 1930, page 486.

Enduro KA2 and similar alloys are being used extensively for auto body trim. Parts are polished after being formed. Polishing materials must be free from Fe. For flat surfaces it is necessary to begin operations with coarser grits than for formed articles. General rule is to use finest abrasive possible. Polishing speed should be 5000–6000 lineal ft./min. First few polishing operations may be done dry; finally, should be done on greased wheels. Buffing must be done with Fe-free compound. For mirror finish special buffing compounds must be used followed by Cr_2O_3. The alloy work hardens very rapidly, and in its fabrication, it is necessary to perform as much work as possible in a single drawing operation and to re-anneal between operations. Blanks used should be of sufficient size so as not to require excessive ironing out in the dies to secure cup depth. Use of a proper lubricant of suitable consistency and body is important. MS(9)

Applying Aluminum in the Wrought Condition. F. V. HARTMAN. *Machine Design*, Vol. 2, June 1930, pages 29–33.

A discussion of the advantageous uses of wrought Al alloys in various machine parts. Gives notes on sheets and tubing, and tables giving composition of wrought Al alloys. Alloys are aged artificially. (9)

White Gold Jewelry. C. M. HOKE. *Brass World*, Vol. 26, Dec. 1930, pages 317–319.

Ag, Ni and Pd are widely used as whiteners of gold. Pd is much more resistant to tarnish and its lower present cost should result in a wider usage. Hints on the manufacture of white Au are made, with suggestions for the man at the bench. WHB(9)

Metals for Modern Boiler Construction. J. GOULD COUTANT. *Blast Furnace & Steel Plant*, Vol. 18, March 1930, pages 476–477.

Properties of steel and alloys at high temperatures must be considered in the design of boiler-room equipment operating at high temperatures and pressures. Shows, by means of examples, how to determine the factor of safety based on yield-point and on creep limit, and thus the maximum temperatures to which steel may be subjected. Factor of safety based on creep limit should be not less than 2 when all conditions are known and about 4 when not known or when there are fluctuations. Includes curves of properties of various steels at temperatures up to 1100° F. MS(9)

The Use of Non-Ferrous Metals in the Aeronautical Industry. D. HANSON. *Metal Industry*, London, Vol. 37, Sept. 12, 1930, pages 247–249, 252; Sept. 26, pages 295–296.

Condensed from the Institute of Metals autumn lecture. See *Metals & Alloys*, Vol. 2, Jan. 1931, page 8. VSP(9)

Making the Steel Equipment Dollar Go Further. FRED D. HARTFORD (Burkhardt & Sons Steel & Iron Works). *Chemical & Metallurgical Engineering*, Vol. 37, May 1930, pages 299–302.

Discusses some factors in the economical use of rolled steel for heavy chemical equipment such as open tanks, blow-cases, tank-car tanks, and filter vessels. Parts subject to corrosive influences should be thickened. Combinations of riveting and welding usually are most economical. MS(9)

Aluminum Alloys in the Transportation Industry. A. H. WOOLEN. *Proceedings Western Railway Club*, Vol. 42, Jan. 1930, pages 20–32.

The Al conduit is finding increased use for protecting wiring on locomotives, cars, shops and engine houses and does not corrode or rust under conditions existing in these locations. See *Metals & Alloys*, Vol. 1, July 1930, page 631. (9)

The Rolling Mill Bearing. (Das Walzenlager.) A. KRETZLER. *Stahl und Eisen*, Vol. 50, May 29, 1930, pages 769–771.

The advantages resulting from a proper selection of the metal for rolling mill bearings as well as the importance of a suitable thickness of the bearing is pointed out. The production of the rolling mill can be increased due to fewer delays in the mill. GN(9)

Aluminum Alloys Used in Commercial Motor-Vehicles. F. D. GOLL. *S. A. E. Journal*, Vol. 27, Dec. 1930, pages 637–645, 654.

The paper is confined to a discussion of Al for commercial motor-truck bodies and tanks. The advantages of Al bodies as to weight saving, low maintenance cost, residual value and better appearance, are stated also, as well as the special advantages applicable to certain types of body now in operation. The paper also treats Al motor-truck tanks in some detail, and presents numerous statistical data in tabular form. (9)

HEAT TREATMENT (10)

Hardening (10a)

On Steel Hardening. (Ueber die Stahlhärtung.) H. ESSER & W. EILENDER. *Archiv für Eisenhüttenwesen*, Vol. 4, Sept. 1930, pages 113–144; *Stahl und Eisen*, Vol. 50, Nov. 13, 1930, pages 1616–1617.

After having proven in preliminary quenching tests that the heat effects occurring during the quenching of steel specimens in water cannot be determined accurately, the quenching was performed by means of gas. The heating and quenching of the samples were performed in vacuum in a container designed for this special purpose. The specimens used were either thin sheets (0.5 to 1 mm. thick, 1–2 mm. wide) or small balls 1–2 mm. in diameter. Quenching curves with varying cooling velocity were taken on C steels from 0.01 to 1.75%. The results permit certain conclusions to be drawn as to the nature of Ar′ and Ar″. The heat effect occurring between 300° and 400° C. with cooling velocities of about 100° to 200°/sec. is assumed to be a tempering effect due to the essentially decreased cooling velocity within this temperature range. In considering these results, the authors arrive at a new explanation for the causes of temper brittleness. A hardening diagram for a cooling velocity of 1000°/sec. is designed, indicating that the heat effects during quenching are similar to the transformations of the Fe-C diagram. It must probably be assumed that martensite is not a pseudo-solid solution but a heterogeneous submicroscopical mixture of α-iron and cementite. It is, furthermore, concluded that all Fe-C alloys, even those with very low C contents, are hardenable if they are sufficiently rapidly cooled. The microscopical investigations are in accordance with the results of the thermal analysis. The development of a new theory of hardness is attempted, which explains the hardness in quenching, the austenite with critical velocity by the following 2 factors: (1) the high degree of dispersion of the cementite; and (2) the pronounced distortion of the α-lattice during the γ-α transformation and the cementite precipitation in the temperature range of a decreased plasticity of the steel. Both factors account for the hardness. GN(10a)

Gas for Lead Hardening of Shovels. C. GEORGE SEGELER (American Gas Ass'n). *Iron Age*, Vol. 125, June 26, 1930, pages 1880–1882.

Advantage of lead hardening is that the high specific gravity of Pb permits the shovels to float in the bath. Describes method used by Baldwin Tool Works, Parkersburg, W. Va. Electricity is employed only when the press of business goes beyond capacity of gas-heated pots. Compares heating values of gas and electricity; character of steel used has bearing. New form of gas heating known as immersion heating is being developed. VSP(10a)

Annealing (10b)

Bright Annealing of Steels in Hydrogen. FLOYD C. KELLEY (General Electric Co.). *American Institute of Mining & Metallurgical Engineers, Technical Publication* No. 388, 1931, 9 pages.

Low carbon steels even when annealed in a stream of purified H_2 are colored blue, and stainless irons are colored green. The color is due to reactions with small amounts of water vapor, which is held in the refractories or leaks into the furnace. The blue color is due to iron oxide and the green color to an oxide of chromium. Low carbon steels can be bright annealed in H_2 by wrapping in sheet iron or by packing in a tube whose ends are closed with sheet iron, but under such conditions the Cr alloys are colored green. The author found that if the Cr alloys were protected with the sheet metal or pipe and then packed in a mixture of alumina and metallic Cr (half and half) they could be bright annealed in H_2. Al, Mn, Si, Fe-Si and Fe-V can replace alumina. A laboratory furnace for the bright annealing of stainless iron and alloys of the 18–8 type, in which the H_2, after preliminary purification, is passed through a mixture of alumina and Fe-Si, is described. The mixture of alumina and Fe-Si is in a second furnace maintained almost at the annealing temperature. For the nickel-chromium iron alloys the annealing temperature was 1100° C., and the flow of H_2 from 2.5 to 5 liters per hour. JLG(10b)

Annealing Brass. BASIL BARHAM. *Metal Industry*, London, Vol. 37, July 25, 1930, page 77.

Treats briefly of a series of experiments carried out to determine the temperature range within which internal stress may be removed from cold worked 70:30 brass without serious reduction of hardness. Discusses also the constitution and mechanical properties of Zn alloys containing Cu up to 10% and Al up to 15%. VSP(10b)

Aging (10f)

The Artificial Ageing of Duralumin and Super-Duralumin. K. L. MEISSNER. *Engineering*, Vol. 130, Sept. 19, 1930, page 358.

Abstract of a paper read before the Institute of Metals, Sept. 1930. See *Metals & Alloys*, Vol. 1, Nov. 1930, page 850. LFM(10f)

Experiments on the Aging of Steel. (Versuche über das Altern von Stahl.) G. SACHS & W. STENZEL. *Metallwirtschaft*, Vol. 9, Nov. 21, 1930, pages 959–965.

Contains 10 references and 16 graphs. Very pure 0.04 C, 4 mm. diameter steel rods were annealed at 940° C. for 1/2 hr. in vacuo, slowly cooled to 200° and quenched in water. They were then twisted 1/2, 1 1/2 and 4 turns in a torsion machine and aged for varying periods at 20° to 100° C. in water, 200° in oil and 300° to 500° in saltpeter, and cooled in air. The physical properties were determined and are shown in the form of graphs. Without twisting, the tensile strength increases 1.3% after 5 months' aging at 20°. The tensile strength of twisted rods increases at 20° up to 30 days, at 100° it reaches a maximum quickly, then decreases. The speed of change immediately after twisting is much greater when aging at 100° than at 20°. With greater amount of twisting, the aging temperature for the greatest change is lower. The effect of alternate twisting and aging was also determined. Other steel rods were quenched at 700° C. in water, which raised the tensile strength from 30.5 to 38.5 kg./mm.^{2} They were then similarly aged and tested. At 20°, there is first a slight drop in tensile strength, then an increase of 52% after 22 days. At 100°, the maximum is reached after 10 min. and it then falls below the original tensile strength. The effect of twisting and quenching is similar. In both cases the maximum effect is reached after days or months aging at room temperature and after several minutes aging at higher temperatures. The maximums decrease with rising temperature. When quenching and twisting are combined, the maximum is reached later than when quenching alone. The theory of the changes is discussed. CEM(10f)

Contribution to the Problem of Dispersion Hardening Based on Experiences Gained with Iron-Alloys. (Zur Frage der Vergütung auf Grund der Erfahrungen mit Eisenlegierungen.) W. KÖSTER. *Zeitschrift für Metallkunde*, Vol. 22, Sept. 1930, pages 289–296; discussion pages 302–303.

Paper before the Deutsche Gesellschaft für Metallkunde, March 1930. See *Metals & Alloys*, Vol. 2, Feb. 1931, page 40. EF(10f)

JOINING OF METALS & ALLOYS (11)

Welding & Cutting (11c)

Development of Welding Department at Carnegie Institute. SAMUEL E. DIBBLE. *Welding*, Vol. 1, Oct. 1930, pages 830–831.

The present status of the department contrasted with its inception in 1916. W(11c)

Cross Wire Resistance Welding. R. S. DONALD. *Welding*, Vol. 1, April 1930, pages 392–394.

Cross wire welding is to-day the accepted method of joining wires or rods since the welded material is stronger and lighter than by any other method of fabrication. Clean material is prerequisite. The size of wire that can be successfully welded is conditioned only by the current that can be economically supplied. It is important not to reduce the cross section of the wire more than one third of its diameter; maximum strength is thereby attained. In general, any kind of wire can be welded; satisfactory results and high production are being obtained on iron, steel, brass, bronze, aluminum and molybdenum nickel, with speeds as high as 180 welds per minute. Elkonite dies are adapted to the speeds required by modern production methods. Electroforging is a new type of cross wire welding, in which the intersection is made into one piece by electroforging under enormous pressure. W(11c)

Proposed Specifications for Fusion Welding of Drums or Shells of Power Boilers. *Journal American Welding Society*, Vol. 9, July 1930, pages 15–41.

Discussion of paper read before the annual meeting of the American Welding Society. LFM(11c)

Welding Theory Needed. *Journal American Welding Society*, Vol. 9, July 1930, page 4.

Preheating Castings for Welding. *Fuels & Furnaces*, Vol. 8, Aug. 1930, page 1160.

Most practical and economic method of preheating large cast iron pieces, particularly where the entire piece is to be heated is the use of a temporary fire-brick furnace. MS(11c)

Electric Arc-Welding of Aluminum. FRED J. GIROUX. *Welding*, Vol. 1, Oct. 1930, pages 838–840.

An aluminum electrode has been developed for arc-welding aluminum that avoids the faults of the oxy-acetylene process. The new process avoids the use of a slag flux cleaner and in most instances the preliminary heating is unnecessary. A perfect autogenous welding of pure aluminum or alloys of other metals is obtained. The aluminum electrode is adapted for the repair of pieces stamped from pure aluminum or cast from light alloys, even though the metal contains a certain proportion of zinc. The method employed is outlined. W(11c)

Are You Going to Weld? T. H. BOOTH. *Welding*, Vol. 1, Oct. 1930, 846–848.

The use of welding on small lot jobs of a wide variety, in contrast to specialized and repetition work has received scant notice. Fundamental factors such as correct design, selection of equipment, shop equipment, the requirements of a good welder, the use of jigs and fixtures, and economic questions are considered. W(11c)

Additional Facts Concerning Welded Bridge Near Lowicz, Poland. STEFAN BRYLA. *Welding*, Vol. 1, Oct. 1930, pages 835–837.

The Polish Ministry of Public Works has prepared a set of specifications for arc welded structures which are the first official specifications for such structures in the world. The total weight of the bridge is 55 tons, as against 70 tons had it been riveted. W(11c)

Problems Met Putting Welding into a Shop. J. B. ROSE. *Welding*, Vol. 1, Jan. 1930, pages 173–177.

The author, a major in the Ordnance Dept. U. S. A., relates the experiences at the Watertown Arsenal, Mass., where the general set-up is designed for production and experimental welding. W(11c)

Joining Light-Gage Sheet Metal by Arc Welding. T. E. JERABEK (Lincoln Electric Co.). *Iron Age*, Vol. 126, Nov. 6, 1930, pages 1309–1310.

Use of electric arc welding in joining sheet metal of No. 14 gage and heavier may be done by using regular metallic or carbon electrodes. With metal lighter than No. 14 gage, and as thin as No. 22 gage the "lightweld" process is used. This process may be used for butt, corner or lap welds on material of No. 16, 18, 20 and 22 gage. Speed of welding on light gage depends on type of joint, gage of material and the set-up. Chief advantage of "lightweld" is that both vertical and overhead welding can be done. VSP(11c)

Automatic Arc-Welding Economies. G. H. KOCH (Westinghouse Electric & Manufacturing Co.). *American Machinist*, Vol. 73, Oct. 16, 1930, pages 621–623.

Discussion of the economic advantages of automatic arc-welding over manual arc-welding. RHP(11c)

Electric Welding. E. W. LEWIS. *Electrical Review*, Vol. 107, Oct. 17, 1930, pages 614–616; Oct. 24, 1930, pages 684–685.

Survey of recent developments such as the production of ductile welds, study of arc phenomena, automatic control, atomic-hydrogen welding, and application to marine, building, railway and bridge construction, chemical equipment and boiler manufacture. MS(11c)

Methods and Machines for Resistance Welding. R. T. GILLETTE (General Electric Co.). *American Machinist*, Vol. 73, July 31, 1930, pages 193–195.

Paper presented before the American Welding Society, New York, Mar. 11, 1930. Published in Journal of the American Welding Society, Vol 9, July 1930, pages 77–82 under the title of Resistance Welding. See *Metals & Alloys*, Vol. 1, Nov. 1930, page 851. RHP(11c)

Welding of High-Pressure Pipe Lines. (Schweissen von Hochdruck-Rohrleitungen.) G. GOHLKE. *AEG Mitteilungen, das Kraftwerk*, No. 1, Jan. 1931, pages 9–14.

Recent experience has shown that it is quite feasible to join high-pressure steam line pipes by welding. Advantages of and conditions for the application of such joints are discussed and several methods are described and illustrated. The result of welding is greater safety in operation, reduced heat losses through leaks, simpler lines and reduced maintenance costs. Ha(11c)

Development and Present Status of Welding Rails. (Die Entwicklung und der Gegenwärtige Stand der Schienenschweissung.) M. REITER. *Stahl und Eisen*, Vol. 50, Nov. 6, 1930, pages 1585–1587.

Abstract of an article in *Organ für den Fortschritt im Eisenbahnwesen*, Vol. 85, 1930, pages 398–405, 419–432. The various methods of welding rails are discussed in the first part of the series of articles. The second part deals with the normalizing of welded rails. The results of the following physical tests are given: tensile tests, cold bending tests, impact bending test, notch toughness tests, endurance impact tests and hardness tests. All methods of welding rails need further improvement. GN(11c)

Manufacture of Electric Welded Pipe. U. A. PETERS. *Rolling Mill Journal*, Vol. 4, April 1930, pages 151–153.

Review of developments in the production of pipe by the electric seam welding. Considers resistance, arc, and roll-electrode methods. MS(11c)

Electric Arc Welding of Aluminum. W. M. DUNLAP. *Welding*, Vol. 1, Sept. 1930, pages 762–766; *Metal Industry*, N. Y., Vol. 28, Oct. 1930, page 470.

Abstract of paper read at fall meeting of American Welding Society, Sept. 22–26, 1930. Discusses application of arc-welding to Al and its alloys investigated by the Research Laboratories of the Aluminum Company of America. Also deals with welding technique and special applications of the process. VSP+AW(11c)

Welding of Iron Under Pressure. (Ueber die Pressschweissbarkeit des Eisens.) H. ESSER. *Archiv für Eisenhüttenwesen*, Vol. 4, Oct. 1930, pages 199–206; *Stahl und Eisen*, Vol. 50, Oct. 23, 1930, page 1500.

The relation between weldability, temperature, pressure, surface and grain size of pure Fe was studied. In additional experiments, the weldability of C steels was also studied. The test specimens were heated within an electrically heated C spiral in vacuum and welded under pressure. The weldability was tested by tensile tests. The influence of the temperature was examined first. In order to eliminate the influence of the surface condition of the faces to be welded, all specimens were polished bright. The pressure was kept constant in this group of tests at 2 kg./mm.^{2} The weldability increased up to 900° C., decreased above this temperature and increased again later. The weldability increases with decreasing grain size, which probably must be traced back to the large number of favorably oriented crystallites present. In 3 groups of tests, the welding pressure was altered, amounting to 1, 2 and 3.5 kg./mm.^{2} The weldability increases with the pressure; the largest increase is shown when the pressure increases from 1 to 2 kg./mm.^{2} The surface condition plays an important role. The maximum values of weldability of polished specimens is reached at 970° C., whereas specimens prepared only on emery paper showed, depending on the grain of the paper, the maximum weldability at 1120° and 1280° C. respectively. The temperature range of good weldability decreases with increasing C content. The relations between temperature, strength of the weld, pressure and C content are illustrated in space diagrams. GN(11c)

Oxy-Acetylene Welding of Sheet Copper. A. EYLES. *Sheet Metal Worker*, Vol. 21, Nov. 28, 1930, pages 725–726, 732.

A practical discussion of the proper technique of oxy-acetylene welding of sheet copper with explanation of requirements for producing good joints. GN(11c)

Welding a 14-Story Building. J. L. FADEN. *Electrical World*, Vol. 96, Nov. 1, 1930, pages 824–829.

The Boston Edison Co's. new home has electric welding throughout. The welders were required to make lap-, fillet-, and butt welds and results of qualification tests are tabulated. Advantages realized by electric welding were: (1) construction noise was virtually eliminated; (2) cost of erecting and welding steel was $3/ton less than with riveted construction; (3) the accident hazard was greatly reduced; (4) fire hazard reduced by elimination of hot rivets; (5) progress of welded construction equalled speed of riveting; (6) welded building frame was more rigid than riveted; (7) alterations made necessary by errors or changes were more easily made than with riveted structure; (8) welding required simpler and less expensive stagings; and (9) smaller gussets were used for wind bracing than when riveting. Several illustrations and tables are included. WHB(11c)

Application of the Theory of the Electric Arc for Welding. (Die Anwendung der Lichtbogentheorie auf die Schweissung.) WILHELM FINK. *Zeitschrift Verein deutscher Ingenieure*, Vol. 74, Nov. 15, 1930, pages 1557–1560.

The author points out what an important part the ionization of the air-gap between the electrodes has and discusses the theory of the arc in its bearing on the welding process. The different characteristics of direct current and alternating current arcs can be explained and the conditions for a steadily burning welding flame derived. It is explained that the transport of material in welding has no connection with the flow of electrons or atoms in the arc. Ha(11c)

Unsolved Problems in Structural Welding. GILBERT D. FISH. *Welding*, Vol. 1, May 1930, pages 453–454.

Brief discussion of the proper use of tension welds, secondary stresses in welded structures, and the practical problem of dividing welding between shop and field. ACW(11c)

Some Fundamentals of Redesign for Arc Welded Steel Construction. R. A. GAST. *Welding*, Vol. 1, April 1930, pages 397–398.

Gives method of making calculations and useful tables for redesigning a cast iron product for arc welded steel construction. To obtain the most efficient arc welded design the product must be redesigned to meet the physical requirements to which it is to be subjected, regardless of resultant shape. ACW(11c)

Welded Open Hearth Charging Machines. A. E. GIBSON (Wellman Engineering Co.). *Blast Furnace & Steel Plant*, Vol. 18, May 1930, pages 796, 817–818; *Welding*, Vol. 1, Apr. 1930, pages 404–406.

Outlines the development of charging machines. With the advent of the very large units, it has been necessary to turn to welding as a means of fabrication. MS(11c)

Electric Welding. C. A. HADLEY (British Electric Welding Machines, Ltd.). *Electrical Review*, Vol. 107, Nov. 28, 1930, page 929.

Extracts from a paper read before the Associated Foremen Smiths of Scotland. Discussion of the process, with special reference to the automatic flash welding machine. MS(11c)

Electrode Research. M. HARAMIISHI. *Welding Journal*, Vol. 27, June 1930, pages 174–177.

Flux-coated and covered electrodes for metallic arc welding are considered. (11c)

Importance of Acetylene Welding in the Construction of Apparatus for the Chemical Industries. (Bedeutung der Azetylenschweissung für den Apparatebau der chemischen Grossindustrie.) H. HOLLER. *Zeitschrift Verein deutscher Ingenieure*, Vol. 74, Nov. 15, 1930, pages 1579–1584.

The chemical industry stands first in the use of welded joints in place of rivets and screws. This article shows a great many illustrations where repairs and alterations on metals other than Fe have been made by welding in a fully satisfactory manner. Ha(11c)

Some Requirements of Arc Welding. R. W. HOLT. *Sheet Metal Worker*, Vol. 21, Nov. 14, 1930, pages 686–688.

The importance of proper designing and preparation of the parent metal upon the efficiency of the results obtained is stressed in the article. GN(11c)

Three-Phase Arc-Welding. (Drehstrom-Lichtbogenschweissung.) HORN. *Zeitschrift Verein deutscher Ingenieure*, Vol. 74, Nov. 15, 1930, pages 1595–1596.

A symmetrical distribution of load on the 3 phases of a 3-phase system is obtained by connecting a high reactance in series with the welding transformer compared with the ohmic resistance of the welding circuit. Then, even with only one arc and 2 phases short circuited, the distribution of the current in the 3 phases will not be very different since the change in ohmic resistance is small compared with the impedance of the circuit. Ha(11c)

Welding of Rustless Steels Is Making Progress. L. W. HOSTETTLER (Allegheny Steel Co.). *Iron Age*, Vol. 126, Nov. 13, 1930, pages 1376–1377.

Taken from a paper read before the American Welding Society. Gives data based on recent experiments. Straight Cr-Fe can be welded by any one of four methods. Light gage material can only be welded by spot weld methods. VSP(11c)

WORKING OF METALS & ALLOYS (12)

Melting & Refining (12a)

Conditions Determining the Action of Refining Agents in the Open-Hearth Furnace. (Abhängigkeitsbedingungen der Frischmittelwirkung im Siemens-Martin-Ofen.) E. KILLING. *Stahl und Eisen*, Vol. 49, Apr. 18, 1929, pages 527–531.

Report 164 of the Steel Mill Committee of the Verein deutscher Eisenhüttenleute. 5 different Fe ores were used in the experiments to determine their relative values as decarburizing agents in the open-hearth process. The results confirm the theoretical conclusion that ores containing a higher amount of Fe_2O_3 are more efficient than those containing a higher amount of FeO. A high content of SiO_2 of the refining agent essentially decreases the economy. GN(12a)

Operation of Open-Hearth Furnaces. *Iron & Coal Trades Review*, Vol. 121, Aug. 8, 1930, page 189.

Abstract of discussion at the semi-annual meeting of the Open-hearth committee of the American Institute of Mining and Metallurgical Engineers, held at Buffalo, N. Y. RHP(12a)

Electrical Melting of Aluminum. (Das elektrische Schmelzen von Aluminium.) E. F. RUSS. *Zeitschrift für Metallkunde*, Vol. 22, Aug. 1930, pages 273–276.

Author recommends the utilization of electrical furnaces for melting of Al on account of advantages generally known and describes in detail his own designs brought on the market. EF(12a)

The Electrodynamic Motion in Induction Furnaces. (Die elektrodynamischen Badbewegungen bei Induktionsöfen.) E. F. RUSS. *Archiv für Eisenhüttenwesen*, Vol. 4, Dec. 1930, pages 277–280; *Stahl und Eisen*, Vol. 50, Dec. 25, 1930, pages 1815–1816.

The author used, in his experiments on a U-shaped hearth induction furnace, a solid conductor to examine the motion of a liquid melt in such a furnace. All previous assumptions that there is a current in the liquid metal which is the cause of the formation of whirls are rejected. GN(12a)

Production of Die-Cast Automobile Parts. *Fuels & Furnaces*, Vol. 8, Jan. 1930, pages 59–60.

Over 50 gas-fired melting pots and die-casting machines are used in production of Al and white metal alloy parts for Lincolns and Fords. All machines operate at 7 lbs./in.^{2} pressure, and the temperature of the pots are 1250°–1400° F. The machines for white metal alloy operate at 1500–1600 lbs./in.^{2}, and the temperature of the pots is 720°–900° F. A cast-iron pot set in a brick foundation and heated with a single gas burner is used for making Pb solder. Solder is recovered from scrap in a gas-fired brick furnace, having the hearth at a 15° angle with the horizontal and concave from side to center. MS(12a)

Two New Methods for the Production of Electric Furnace Iron. G. L. SIMPSON. *Fuels & Furnaces*, Vol. 8, July 1930, pages 939–940.

Abstract of paper read before the American Electrochemical Society. See *Metals & Alloys*, Vol. 1, Sept. 1930, page 736. MS(12a)

The Finishing of Refined Thomas Pig Iron in the Open Hearth Furnace. (Das Fertigmachen von vorgefrischtem Thomasroheisen im Siemens-Martin-Ofen.) A. JUNG. *Stahl und Eisen*, Vol. 49, Aug. 22, 1929, pages 1221–1226.

Includes discussion. Report 172 of the Steel Mill Committee of the Verein deutscher Eisenhüttenleute. Gives the results of investigations which were carried on for the purpose of studying the economics of the duplex method, i. e., the steel charge was first refined in the Thomas converter and finished in the open-hearth furnace. The metallurgical process was studied and the furnace capacity and fuel consumption determined. Rules for the economic considerations are outlined. GN(12a)

Cupola Melting of Bronze. E. R. DARBY. *Metals & Alloys*, Vol. 1, Nov. 1930, pages 812–813.

The use of the cupola or shaft type furnace for casting purposes is the result of very recent developments. It became possible with development of pitch coke by the Barrett Co. This fuel contains no ash, very little S, and better than 99% fixed C. The furnace and its operation are described in detail. Alloys containing up to 10% Pb may be melted. Cases as high as 20% have been successfully handled. However, in the latter instance, it is advisable to charge not in excess of what may be tapped into a single ladle. Alloy containing up to 5% Zn may be treated although losses are quite heavy. 85–5–5–5 bronze will lose over 60% of its Zn. The losses of Cu and Sn are negligible if the particles are not so small as to be carried away by the blast. P, free Fe and Al are almost entirely eliminated. Continuous operation of a furnace for 8 or 9 hours yields a fuel ratio of 1 to 14. With a fuel cost of $33.00 per ton, the melting cost is 12¢ cwt. ESC(12a)

A Contribution to the Problem of the Analysis of Basic Slags and the Representation of Their Composition in a Triangular Diagram. OTAKAR QUADRAT. *Engineering*, Vol. 130, Sept. 26, 1930, pages 404–405.

Abstract of paper read before the Iron & Steel Institute, Prague, Sept. 15, 1930. See *Metals & Alloys*, Vol. 1, Dec. 1930, page 915. LFM(12a)

The Decarburization of Iron in the Open-Hearth Furnace and the Concentration of Free Ferrous Oxide in Basic Slags. HERMAN SCHENCK. *Metals & Alloys*, Vol. 1, Aug. 1930, pages 674–677.

A translation. The law of mass action is applied to the open-hearth system on the basis that the C content of the metal must of necessity bear a relation to the concentration of the free FeO. Various conceptions of the value to be used for the constant (FeO) are discussed. It is only possible to ascertain a relation between C content and FeO concentration if part of the Fe contained in the slag is considered as being combined in the form of lime ferrite. Evidence is presented to indicate these data and may be used to judge the heat for the quality of steel. See *Metals & Alloys*, Vol. 1, Sept. 1930, page 736. ESC(12a)

Continuous Electric Melting of Cast Iron. H. W. GILLETT. *Metals & Alloys*, Vol. 1, Aug. 1930, pages 672–673.

A correlated abstract. Two new methods for operating the electric furnace to give a continuous flow of metal during the working day have recently been developed. In the continuous duplexing process, the metal is melted in the cupola with just as little coke as will make it run properly and fed into the electric furnace where materials are added to give the desired composition, and the metal is superheated to the desired temperature. A full bath is maintained in this furnace and at regular intervals a batch of refined and superheated iron is tapped off. The continuous melting process utilizes the electric furnace alone. The charge is melted, the composition corrected, the temperature raised to the desired value and a small ladle of molten metal tapped off. Immediately, the equivalent amount of cold metal is charged through the rear door of the furnace. In both processes the furnace load is discharged at the end of the day's work. A 3-ton electric furnace installation in continuous operation has shown 25–30% increase in production, reduction of cost, and greater flexibility to cope with rush orders. Data are given regarding costs. The melting practice is readily adapted to desirable results. The feed charges consist of foundry returns and stove plate scrap without additional alloys. ESC(12a)

Drawing & Stamping (12h)

Standard Brake Dies of Simple Design. Parts VI–IX. GLENN A. BARTH (Barth Stamping & Machine Works). *Metal Stampings*, Vol. 3, Jan. 1930, pages 53–55; Feb. 1930, pages 147–148; April 1930, pages 339–340; May 1930, pages 439–440, 476.

Discusses construction of dies required for the formation of lock seams and the Pittsburgh lock; application, design, and operation of special brake dies; combination brake die; and adaptability of press brakes for piercing and notching operations. MS(12h)

Drawing Qualities of Sheet Steels for Automobiles. W. H. GRAVES (Packard Motor Car Co.). *Metal Stampings*, Vol. 3, May 1930, pages 443–444.

From paper read before American Society for Testing Materials. See *Metals & Alloys*, Vol. 1, July 1930, page 633. MS(12h)

The Manufacture of Solid Drawn Gunmetal Tubes. EDWARD S. RICHARDS. *Metal Industry*, London, Vol. 37, Aug. 8, 1930, page 133.

Solid drawn gunmetal tube making presents many difficulties. Describes the manufacture of a solid drawn gunmetal tube of the following analysis:

Sn	4%
Pb	2%
Zn	5%
Cu	88% to 89%
Fe	Nil.

VSP(12h)

Power Consumption and Physical Properties in Drawing Low Carbon Steel with Increased Speed. (Kraftverbrauch und Werkstoffeigenschaften beim Ziehen von Stahldraht mit erhöhter Ziehgeschwindigkeit.) A. POMP & W. BECKER. *Mitteilungen Kaiser Wilhelm Institut für Eisenforschung*, Vol. 12, 1930, Report 161, pages 263–284; *Stahl und Eisen*, Vol. 50, Dec. 4, 1930, pages 1723–1724.

Three steels, as listed below, were drawn with gradually increased speed, to study the power consumption and the influence of the structure:

Material	C%	Si%	Mn%	P%	S%
A: Open hearth steel	0.065	..	0.33	0.026	0.046
B: Thomas steel	0.080	..	0.39	0.054	0.040
C: Silicon open hearth steel	0.070	0.25	0.41	0.009	0.060

These steels were drawn partly direct down from the rod (5.3 mm.) and partly drawn down to 3 mm. wire, pot annealed at 850° to 900° C. and drawn to 1.8 mm. wire. The drawing speed was increased from 2.3 to 7.5 m./sec. At the higher speeds, the power consumption decreased by about 5%. The power consumption figures obtained were used to plot diagrams in order to predetermine for any wire the power consumption of the subsequent draft. Drafting with increased speed did not impair the physical properties of the wire as determined by tensile tests, elongation, reduction of area, bending and twist tests. The life of the dies, as determined by the tonnage drawn, was in most cases longer for the high speed than for the slow speed. The only difficulties encountered in drawing with increased speed results from stringing. GN(12h)

Press Working and Forming of Metals. Parts XX, XXII–XXIX. E. V. CRANE (E. W. Bliss Co.). *Metal Stampings*, Vol. 3, Jan. 1930, pages 27–33; March 1930, pages 221–226, 248; April 1930, pages 313–319; May 1930, pages 413–418; June 1930, pages 521–526; July 1930, pages 629–632, 652; Aug. 1930, pages 725–726; Sept. 1930, pages 811–814; Oct. 1930, pages 887–890.

Deals with multiple drawing dies and operating problems involved in metal working operations; volume changes, flow of metals, and pressures involved in squeezing operations; squeezing operation involved in the cold sizing and surfacing of stampings, forgings, and castings; changes of yield-point with cold working of metal, and cold forging operations, especially in soft steel and Cu; typical cold swaging operations in these metals; developments in coinage practice; characteristics and typical applications of embossing operations in sheet-metal; and typical applications and methods of press extrusion. Compression tests were carried out on 2 blanks, $^3/_4$ in. in diameter and $^1/_2$ in. high, of machine steel with 0.15% C. The yield-point in compression rose from 37,000 lbs./in.^{2} in the annealed state to 115,000 lbs./in.^{2} when reduced to half the original thickness. The Brinell hardness number rose from about 120 to approximately 240. Re-annealing reduced the yield-point to 45,000 lbs./ in.^{2} and further compression again raised it to 95,000 lbs./in.^{2} Part XXI was abstracted in *Metals & Alloys*, Vol. 1, July 1930, page 634. MS(12h)

Polishing & Grinding (12l)

Polishing Stainless Steel and Rustless Iron. L. R. EASTMAN (Frederic B. Stevens, Inc.). *Metal Cleaning & Finishing*, Vol. 2, March 1930, pages 221–225.

Small parts are polished in one operation with a No. 200 or flour size abrasive. In some cases, a No. 180 abrasive may be necessary followed by the 200 wheel. Larger areas of flat or nearly flat surfaces are polished with a No 150 dry, then a 180 tallow, and finally a 200 tallow wheel. Still larger surfaces require a No. 180 artificial, dry; 180 emery, dry; 180 artificial with tallow; then 200 emery, with grease. The buffing abrasive must be hard and fine enough to produce a high finish, and the binder must be capable of holding the abrasive on the wheel and lubricating the buff. High, uniform pressures and a peripheral speed of about 10,000–12,000 ft./min. are necessary for buffing. A composition similar to the buffing compound, but usually dryer and with less cutting qualities is generally used for coloring. MS(12l)

DEFECTS (13)

The Nature of the Flakes in the Chrome-Nickel and Chromium Steels. A. L. BABOSHIN. *Metallurgist* (Leningrad, Russia), No. 2, 1929, pages 206–215. (In Russian.)

Taking into consideration all the data in literature and the results of his own observations, the author comes to the following conclusions: (1) flakes are only observed in those steels (a) in which the location of critical points depend to a great extent upon the rate of cooling and the temperature of heating, or (b) which show a well pronounced dendritic structure—a great majority of such steels are Cr-Ni, Mn, and Cr steels; (2) the principal factor (beside composition) determining the appearance of flakes are cooling conditions of metal (ingots, forgings, etc.); (3) cracks (flakes) are caused by stresses resulting from (a) the sudden changes in volume during the normal cooling conditions, or (b) non-uniform cooling of the outer and inner portions of forgings; (4) all the conditions promoting the factors cited in (1) and (3) or reducing the resistance of metals to the internal stresses promote the formation; in particular, larger Cr and Mn contents of the Cr-Ni steels of a normal composition, other conditions being equal, promote the presence of flakes; insufficient deoxidation of metal or impurities as well as blowholes also promote flakes. AIK(13)

Tracing the Cause of Defects. ALBERT J. BOND. *Foundry*, Vol. 58, June 15, 1930, page 75.

Describes method of tracing defects. Pressure castings often show high % of leaks under test. These are caused by sand holes, flakes of oxide or shrink cracks. Defects in flanged castings were due to failure of metal to cover the core on casting. Using good cores and careful molding, sound castings are produced. Cites other examples of defects and their causes. VSP(13)

Non-Metallic Inclusions in Iron and Steel. C. BENEDICKS & H. LÖFQUIST. John Wiley & Sons, New York, 1931. Cloth, 6 × 9 $^3/_4$ inches, 311 pages. Price $8.00.

This book covers work at the Swedish Metallographic Institute done in part on a scholarship, presented by Sir Robert Hadfield, and in part with the financial support of Jernkontoret, the Swedish Iron Masters' Association. It is largely the result of a survey of the literature and contains some 800 references. The meticulous care taken to state in the text, in parenthesis and italics, the name of each worker to whom is due a fact or an opinion ought to delight the British reviewers who are so touchy when anyone cites a fact that may have been unearthed by some British worker, among others, without pausing to give detailed credit every time it is mentioned. Nevertheless, this constant breaking up of the text is irritating to the eye and makes it more difficult to follow the argument.

The equilibria between iron and the various constituents of the non-metallic inclusions are considered in detail, as are the binary and ternary diagrams for oxides, sulphides, silicates, etc., in the slags themselves.

The properties of some 20 materials that may occur as non-metallic inclusions are given in a large table. Much attention is paid to the Campbell-Comstock-Wohrman scheme for metallographic recognition of the constitution of inclusions. Chemical methods for quantitative analysis are mentioned in less detail.

The mechanism of the formation and the release or retention of inclusions in melting and pouring processes, the distribution of the inclusions during crystallization, and the general problems of segregation, blowhole formation, banded structure and flakes are relatively briefly discussed.

The effect of inclusions on mechanical properties is given a dozen pages.

The practical suggestions as to possible means of reducing the content of non-metallic inclusions, given in the last half-dozen pages, in general, accord fairly well with the trend of Herty's investigations.

The general impression one gets from the book is that a vast amount that ought to be known for a fully intelligent attack on the problem of non-metallic inclusions has still to be found out. This critical compilation of the results of the large amount of work already done and recorded in many thousands of pages in the original papers will be of service to those interested in the problem.—H. W. Gillett (13)-B-

CHEMICAL ANALYSIS (14)

Determination of Carbon in High Sulphur Steels by Direct Combustion. H. A. BRIGHT & G. E. F. LUNDELL. *Bureau of Standards Journal of Research*, Vol. 5, Oct. 1930, pages 943–949.

Oxides of sulphur are formed in the direct combustion method for carbon in steel and cause positive errors if they are not removed. The absorbents commonly used for this purpose, as well as promising new ones, have been tested. A description is given of the absorption train that has been developed at the National Bureau of Standards as well as one that has been developed by the Jones & Laughlin Steel Co. (14)

The Analytical Chemistry of Element 91, Ekatantalum, and Its Difference from Tantalum. ARISTID V. GROSSE. *Journal American Chemical Society*, Vol. 52, May 1930, pages 1742–1747.

The unsuccessful attempts to isolate and obtain element 91 were based on the assumption that it resembles its lower homolog-tantalum—just as radium resembles barium. This article describes the analytical chemistry of ekatantalum and verifies the predictions of Mendelejeff's law. The behavior toward different reagents is in most of the cases observed, opposite to that of tantalum. Ekatantalum pentoxide is a distinctly, though feebly, basic oxide without acidic properties, whereas tantalum pentoxide is an acid anhydride and readily forms stable salts with basic oxides. MEH(14)

The Importance of Particle Size in Samples of Certain Metallurgical Materials. J. A. SCHERRER & G. E. F. LUNDELL. *Bureau of Standards Journal of Research*, Vol. 5, Oct. 1930, pages 891–895.

The sampling of certain metallurgical materials gives rise to particles that differ in size and in composition. The extent of the difference is shown and the procedures that must be followed in selecting the sample for analysis are outlined. (14)

Quantitative Spectrum Analysis by X-Rays. (Quantitative Spektralanalyse mit Röntgenstrahlen.) G. V. HEVESY. *Metallwirtschaft*, Vol. 9, Sept. 26, 1930, pages 801–804.

Contains 12 references. Minerals and metals can be analyzed quantitatively by examining their spectrum with X-rays. The intensity of the characteristic line of an element depends on the other elements present. The percentage of an element is determined by mixing a known quantity of another element with the unknown sample and comparing the intensity of its line. This element must not already be present in the sample. Rare elements such as Hf are usually used. The intensity of the line to be determined and of the line of the comparison element must be influenced to the same degree by other elements present in the sample. The suitability and limitations of various elements for comparison purposes are discussed. Examples are worked out for determining (1) Ti in iron meteorites, (2) Small percentages of Pb in Zn, (3) K in soils and (4) Nb and Ta in volcanic minerals. CEM(14)

A Rapid Method for the Determination of Antimony in a High Copper Alloy. JOHN B. KASEY. *Chemist-Analyst*, Vol. 19, Sept. 1930, page 9.

The sample is dissolved in HNO_3, HCl mixture and an excess of NH_4OH added. $(NH_4)_2CO_3$ and paper pulp are added and the solution filtered. The bulk of the Cu remains in the filtrate. The precipitate is dissolved in H_2SO_4 and HNO_3, tartaric acid is added and the solution heated until it turns amber color. Pass in H_2S to precipitate Sb and fume to SO_3. Add $KHSO_4$ and after boiling out H_2O add pure S and fume for $^1/_2$ hour. Cool, dilute, add HCl and titrate with $^1/_{10}$ N $KMnO_4$. If As is present, separate by Stief method before titrating. CEM(14)

Quantitative Analysis of Iron Alloys by Means of X-Ray. SHIGETAKA SHIMURA & MASAO TAKASU. *Tetsu to Hagane*, Vol. 16, Sept. 25, 1930, page 961–970.

The article deals with quantitative analysis of Fe-Ni-Mn alloys by means of radiation spectrum. The 4 alloys used in this study were prepared in an electric furnace using electrolytic iron, metallic manganese and metallic nickel. These alloys contained 3.6–13% Mn, and 3–10% Ni. The characteristic X-Ray was produced by Hadding tube, analyzed with a spectrograph and then exposed to a dry plate. The intensity of the K-series lines was measured by a Noll's microphotometer, and from the values thus obtained the contents of Mn and Ni were calculated. The results obtained often differed widely from the actual contents; that is 0–25% errors for Mn and 0.5–15% for Ni. The authors added that this error will be reduced by replacing plates used and by more skilful manipulation of photometer. TS(14)

The Importance of Sampling in the Metal Industry. (Die Bedeutung der Probenahme für den Metallhandel.) WILHELM KLUTE. *Metallwirtschaft*, Vol. 9, Jan. 17, 1930, pages 72–73.

Since the war the use of secondary metals has increased. The success or failure of their use depends on proper sampling. Analyses on duplicate samples should check within $^1/_2$%. Experienced samplers are necessary. Price of secondary metals is often based on analysis of samples. CEM(14)

Physico-Chemical Measurements (Hand- und Hilfsbuch zur Ausführung physikochemischer Messung). C. DRUCKER. 5th Edition of the Ostwald-Luther Handbook. Akademische Verlagsgesellschaft, Leipzig, 1931. Cloth, 6 × 9 1/2 inches, 979 pages. Price 52 RM.

The first edition of Ostwald's handbook was issued in 1893 and has been used by many generations of college students. The fourth edition came out in 1925. While all chapters have been revised and expanded by Drucker and a group of able collaborators, the chief addition is in regard to the use of electron tubes.

Drucker points out that many old methods of and devices for physico-chemical measurements are as worthy of description and use as some more modern and complicated ones, and in fact, are often more simple and much cheaper. Hence a large part of the book is not essentially different from the old Ostwald-Luther the reviewer used 25 years ago.

The field covered is so very wide that a detailed coverage would be out of the question. Drucker has wisely chosen to deal with principles and with the simpler types of apparatus rather than to cover highly refined and specialized equipment. Fairly full references are given, through which more detailed information can be found, but on the whole the handbook seems designed to cover such apparatus as is required in undergraduate laboratory courses in physico-chemical measurements rather than in advanced research work. In the treatment of calorimeters, thermostatic control, high vacua, and laboratory electric furnaces, for example, necessary details on special apparatus necessary for refined work may be traced only through the footnote references, if at all. The type of equipment built up chiefly by the glass blower is rather thoroughly dealt with, but mechanical and electrical equipment such as chronographs, oscillographs, potentiometer controllers, etc., scarcely receives mention. The physical chemist dealing with aqueous solutions will find a great deal of value in the book. The physical metallurgist will find something of value but will not find information on a very large proportion of the types of measuring equipment he needs for advanced work. A notable exception is, however, the fact that the elements of X-ray spectrography are discussed.

Within its limitations, the volume is a very valuable handbook.—H. W. Gillett (14)-B-

Sampling for the Determination of Average Metal Content of Ores. (Ueber Probenahme zur Ermittlung des Durchschnittsmetallgehaltes von Roherzen & des Aufbereitungserfolges.) JOHN E. BARNITZKE. *Metall und Erz*, Vol. 27, Feb. 1930, pages 53–66; April 1930, pages 179–187.

The difficulties of obtaining a true average in sampling ores are pointed out. Instructions are given for the best procedure and the theory for sampling well mixed and unmixed ore is discussed. The methods of taking large quantities at longer intervals and small quantities at shorter intervals are compared. The conditions for a representative sample are stated. The probable percentage error should be known. The methods of sampling formerly used are not reliable. CEM(14)

HISTORICAL & BIOGRAPHICAL (15)

When Forging Was Young. CHESTER B. LORD. *American Machinist*, Vol. 73, Sept. 18, 1930, pages 467–470.

Historical review. Deals sketchily with various ancient steels and methods of working. Hand hammering is given much credit for the quality of the ancient steels. RHP(15)

Furnaces in the Hanging Rock District. H. H. HOPKINS. *Blast Furnaces & Steel Plant*, Vol. 18, Sept. 1930, pages 1451–1452.

Outline of the history of blast furnaces, now dismantled, near Ironton, Ohio. MS(15)

Heat Treatment of Ancient Implements. H. C. H. CARPENTER & J. M. ROBERTSON. *Heat Treating & Forging*, Vol. 18, July 1930, pages 869–871, 875.

From a paper "Metallography of Some Ancient Egyptian Implements," read before the Iron & Steel Institute. See *Metals & Alloys*, Vol. 1, Sept 1930, page 739. MS(15)

ECONOMIC (16)

Gold and Silver in 1928. J. P. DUNLOP. *Mineral Resources of the United States*, 1928, Part 1, *United States Bureau of Mines*, November 6, 1930, pages 873–910.

Gold was produced in 18 states, Alaska and the Philippine Islands in 1928, to a total amount of 2,233,251 fine ounces. California led with 513,249 ounces, Alaska was second with 330,604, and South Dakota third with 318,095. This represented an increase of 36,126 ounces over 1927. California showed the greatest decrease (51,732 ounces) among 6 decreasing state productions and Alaska the greatest increase (44,306 ounces). Silver totaling 58,462,507 fine ounces was produced in 20 states, Alaska and the Philippine Islands in 1928. Utah led with 17,749,317 ounces, Montana was second with 10,681,675 and Idaho third with 8,949,716. This represents a decrease of 1,971,934 ounces. Utah showed the greatest drop in production (1,604,441 ounces) and Texas the biggest increase (451,694) among 10 states increasing output. Arts and manufactures used 68% of the new gold and 43% of the new silver. Figures are given for world production by countries for 1923 to 1928. AHE(16)

Platinum and Allied Metals in 1929. HUBERT W. DAVIS. *Mineral Resources of the United States*, 1929, Part 1, *United States Bureau of Mines*, October 28, 1930, pages 57–71.

Mine production of crude platinum in the United States in 1929 was 797 ounces, 528 from Alaska, 246 from California and 23 from Oregon. Production in 1928 was 528 ounces. Refinery recovery of platinum metals in 1929 was as follows: platinum 41,760 ounces, palladium 5295, iridium 302, osmiridium 364, others 256, total 47,977, a decrease of 18% from 1928. Of this, 10,886 ounces was derived from domestic sources. Secondary metals in this group in 1929 totaled 42,759 ounces. World production and occurrence by countries are discussed. AHE(16)

Iron Ore, Pig Iron and Steel in 1929. HUBERT W. DAVIS. *Mineral Resources of the United States*, 1929, Part 1, *United States Bureau of Mines*, October 22, 1930, pages 5–44.

In 1929 the production of iron ore (73,027,720 tons) increased 17% over 1928; the output of pig iron, including ferro-alloys (42,613,983 tons) increased 12%. Iron ore was mined in 18 states, Minnesota leading with 45,760,858 tons, Michigan being second with 15,456,397 and Alabama third with 6,453,075 tons. Pig iron (plus ferro-alloys) was produced in 18 states, Pennsylvania leading with 14,453,251 tons, Ohio being second with 9,795,648 and Illinois third with 4,357,971 tons. Ferro-alloy production increased 4% to 829,324 tons. Steel output increased 9% over 1928 to 56,433,473 tons. Of this, 85.7% was open hearth, 12.6% Bessemer, and 1.7% other classes. AHE(16)

Iron and Steel in Canada. *Iron & Coal Trades Review*, Vol. 121, Aug. 1, 1930, page 156.

Abstract of a report of F. W. Field on "Economic Conditions in Canada" (to May 1930). Discusses imports, production, railway equipment and shipbuilding. RHP(16)

Coal and Iron in Belgium in 1929. *Iron & Coal Trades Review*, Vol. 121, July 18, 1930, page 88.

Abstract of the report by N. S. Reyntiens in his Report on Economic Conditions in Belgium in 1929, issued by the Department of Overseas Trade of England RHP(16)

Cost System in the Heat Treating Plant. J. J. BERLINER. *Heat Treating & Forging*, Vol. 16, May 1930, pages 614–616.

Outlines system of determining the costs of the various heat-treating operations MS(16)

Coke and Iron in Sweden. *Iron & Coal Trades Review*, Vol. 121, July 11, 1930, page 48.

Abstract of a report on "Economic Conditions in Sweden," by W. J Glenny issued by the Department of Overseas Trade and published by H. M. Stationery office. RHP(16)

Iron and Steel Imports and Exports in the First Half of 1930. *Iron & Coal Trades Review*, Vol. 121, July 18, 1930, page 85.

Reviews the imports and exports by months for Jan.–June 1930. By product and by country for 1913, 1929, and Jan. to June 1930. RHP(16)

Engineering Markets of the World. V. A. J. LIVERSEDGE. *Engineering*, Vol. 130, Oct. 10, 1930, pages 452–454.

Review of import situation in British Africa. Commodities discussed include iron and steel and manufactures thereof, electrical apparatus, machinery, railway plant and stock, and motor vehicles. Although the Union of South Africa gives preference to British made goods, imports from the United Kingdom are steadily falling off. In iron and steel Germany is England's chief competitor, Belgium is second and U. S. third. Figures and curves show imports from 1913 to 1929. Curves for all commodities from United Kingdom end on lower levels than where they began in 1913 and are also lower than they were in 1925. LFM(16)

Cost Calculations of Light Metal Castings. (Kostenaufstellung bei Leichtmetallguss.) W. HOFFMANN. *Zeitschrift für Metallkunde*, Vol. 23, Jan. 1931, page 25.

Author developed a formula and gives diagram to calculate cost of castings of various metals and alloys with particular reference to light metal castings. EF(16)

Gold, Silver, Copper, Lead and Zinc in the Eastern States in 1929. J. P. DUNLOP. *Mineral Resources of United States*, 1929, Part I, *United States Bureau of Mines*, November 12, 1930, pages 73–78.

The mines of the Eastern States yielded metals in 1929 valued as follows: Au, $36,793; Ag, $59,515; Cu, $5,992,082; and Zn, $21,920,456. Both the quantity and value of all 5 metals except Ag, increased in 1929 over 1928. AHE(16)

Magnesium and Its Compounds in 1929. PAUL M. TYLER. *Mineral Resources of United States*, 1929, Part II, *United States Bureau of Mines*, Nov. 20, 1930, pages 119–138.

The domestic output of virgin ingot increased from 521,075 lbs. in 1928 to 1,329,669 lbs. in 1929 (155%). Much progress has been made in the development of extrusion, forging and other fabrication methods. AHE(16)

Copper in 1928. C. E. JULIHN & H. M. MEYER. *Mineral Resources of the United States*, 1928, Part 1, *United States Bureau of Mines*, Oct. 6, 1930, pages 705–759.

In 1928, world Cu production (1,878,000 short tons) was supplied as follows: United States, 53.49; Chile, 16.31; Belgian Congo, 6.60; Japan, 3.87; Canada, 3.32; Peru, 3.07; Germany, 2.85; Mexico, 2.29; Spain, 1.63; Great Britain, 1.35; Russia, 1.17; and other countries 4.05%. This was an increase of about 12% over 1927, only 4 countries having decreasing productions. The United States and 5 other countries dropped in their % of the world's total (U. S., 2.07%). Cu production in the United States increased 8.01%. Trends are indicated by Canada's increase of 77% over 1927, Chile 23% and Congo 26%. AHE(16)

PLANTS & LABORATORIES (17)

Sheet Metal Enameling Process Mechanized. C. B. PHILLIPS (Surface Combustion Co.). *Ceramic Age*, Vol. 15, May 1930, pages 281–282.

Describes the installation for vitreous enameling of sheet metal at the Harvey, Illinois, Plant of the American Stove Company. WLC(17)

Heat Treating Motorcycle Parts. C. B. PHILLIPS (Surface Combustion Co.). *Iron Age*, Vol. 126, July 24, 1930, pages 221–224.

Describes heat treating equipment of Harley-Davidson Motor Co., Milwaukee. A continuous furnace which can be used interchangeably for various kinds of heat treating is used. Carburizing is done in batch-type furnace. Insulation of continuous furnace is inside steel casing. Miscellaneous hardening is done in a rotary type furnace provided with both an oil and water quench. Gas fuel is employed. VSP(17)

Heat-Treating Alloy Steel Airplane Parts. C. B. PHILLIPS (Surface Combustion Co.). *Machinery*, Vol. 35, Aug. 1929, pages 943–945.

Describes the heat-treatment work of the Fairchild Airplane Mfg. Corp., Farmingdale, Long Island, N. Y. See *Metals & Alloys*, Vol. 1, Feb. 1930, page 388. RHP(17)

Battelle Memorial Institute. R. RIMBACH. *Metals & Alloys*, Vol. 1, Oct. 1930, pages 770–774.

The Battelle Memorial Institute was founded by Gordon Battelle to provide for carrying on pure and industrial research. It is a non-profit making organization, so industrial projects are merely self-supporting. The building is attractively constructed and provides generous space for future development. The library promises to compare favorably with the best of its kind. A brief discussion of activities now in progress is offered. ESC(17)

The New Research Laboratory of the Aluminum Co. of America. R RIMBACH. *Metals & Alloys*, Vol. 1, Sept. 1930, pages 717–720.

A detailed description is given of the structure, arrangement and equipment of the New Kensington laboratory of the Aluminum Co. of America. A number of photographs are included. ESC(17)

The Research Laboratories of the New Jersey Zinc Co. RICHARD RIMBACH. *Metals & Alloys*, Vol. 2, Jan. 1931, pages 13–17.

A description of that portion of the Research Division of the Technical Department of the New Jersey Zinc Co. which is devoted to metallurgical studies. A number of photographs are included showing equipment utilized for this work. ESC(17)

New Buttweld Pipe Mill Equipped with Regenerative Furnace. F. B. PLETCHER. *Iron Trade Review*, Vol. 86, May 8, 1930, pages 52–55.

Describes plant of the Laclede Tube Co., Alton, Ill. Includes galvanizing and enameling equipment. MS(17)

The Basic-Bessemer Steelworks of the Mannesmann Tube Works. J. POSTINETT. *Iron & Coal Trades Review*, Vol. 121, Aug. 29, 1930, pages 292–293; Sept. 5, 1930, pages 326–327.

Taken from *Stahl und Eisen*. See *Metals & Alloys*, Vol. 1, Nov. 1930, page 854. RHP(17)

Completes Third Hot Strip Mill. J. B. PLETCHER. *Iron Trade Review*, Vol. 86, March 20, 1930, pages 41–44.

Illustrations with brief description of the new continuous unit of the Acme Steel Co. at Riverdale, Ill. MS(17)

Rolling Wire for the Hudson River Bridge. CHARLES LONGENECKER. *Blast Furnace & Steel Plant*, Vol. 18, Aug. 1930, pages 1280–1284.
Describes equipment, particularly the rolling mills, of the Kinkora Plant of the John A. Roebling's Sons Company at Roebling, N. J. MS(17)

Inland's 10-in. Mill Goes into Operation. CHARLES LONGENECKER. *Blast Furnace & Steel Plant*, Vol. 18, Oct. 1930, pages 1599–1601.
Describes new continuous merchant bar mill and accessory equipment of the Inland Steel Company, Indiana Harbor, Ind. MS(17)

Hot Strip Mill at Acme Steel Company. A. F. KENYON (Westinghouse Electric & Mfg. Co.). *Blast Furnace & Steel Plant*, Vol. 18, Aug. 1930, pages 1297–1301.
Describes continuous mill at Riverdale, Ill., with particular emphasis upon the electrical drives and controls. MS(17)

Line Production the Keynote of New Pratt & Whitney Aircraft Plant. J. W. MARSHALL. *Iron Age*, Vol. 126, July 17, 1930, pages 152–155, 202–203.
Describes new $2,000,000 plant at East Hartford, Conn., for the manufacture of Wasp and Hornet Motors. Main factory building is 1000 ft. long with 400,000 sq. ft. of floor area. All Al parts are machined in one part while steel in another. Tool room and master crib are centrally located. Assembled engines are tested and then torn down for inspection. Plant addition can be made without interruption of production. VSP(17)

Apply Continuous Process to Malleable Practice. B. R. MAYNE (Saginaw Malleable Iron). *Foundry*, Vol. 58, May 15, 1930, pages 61–64, 90.
A steady supply of metal is essential in continuous molding operation. Describes plant of Saginaw Malleable Iron at Saginaw, Michigan. Melting equipment consists of three 90-in. shell cupolas; three 10-ton oval shaped fore-hearths; one 3-ton electric crane and two 3-ton electric furnaces. Metals at cupola average 2800° and electric furnace 2950° F. VSP(17)

Oil Fired Batch Type Furnaces Used in Annealing Aluminum Sheets and Strip. *Fuels & Furnaces*, Vol. 8, Feb. 1930, pages 261–262.
United States Aluminum Co., Edgewater, N. J., has installed 4 new batch furnaces with one double-pass firing chamber located on each side of furnace and has remodeled 4 furnaces with Carbofrax top on firing chamber. Furnace temperature of about 900° F. is maintained. Duration of heat depends on various factors and ranges from 2–18 hrs., with an average of about 4 hrs. MS(17)

Aluminum Invades the Structural Field. *Chemical & Metallurgical Engineering*, Vol. 37, March 1930, page 143.
Brief description of the rolling-mill at the Massena, N. Y., plant of the Aluminum Company of America. MS(17)

Plating Department Design at Crosley. D. W. MACDONALD. *Metal Cleaning & Finishing*, Vol. 2, June 1930, pages 477–482, 528.
Describes plant layout, equipment, and plating procedure of the Crosley Radio Corporation. MS(17)

Heat Treatment of Motorcycle Parts. *Fuels & Furnaces*, Vol. 8, Aug. 1930, pages 1041–1044.
Describes equipment and practice of the Harley-Davidson Motor Co., Milwaukee, Wis. Among the steels used are S. A. E. 3115, 3140, and 3245. Furnaces include batch type carburizing furnace, continuous automatic furnace used interchangeably for various kinds of heat treating, periodic furnaces for miscellaneous work, lead pots, cyanide pots, and rotary type hardening furnace. MS(17)

Interesting Installation for Production of Galvanized and Japanned Strip Steel. *Fuels & Furnaces*, Vol. 8, July 1930, pages 917–921.
Describes plant of the Acme Steel Company at Riverside, Ill. Strip is annealed in a Pb bath, pickled and galvanized, or annealed and japanned in continuous type equipment. MS(17)

A large Italian Electric Steel Making Plant. (Une grande usine electro-siderurgique italienne.) *Journal du Four Electrique*, Vol. 39, Sept. 1930, pages 339–340.
Vulcano Works at Sesto San Giovanni recently completed the installation of a series of electric furnaces of conducting bottom type. Six rated at 1500 KW and one at 750 KW are used for preparation of ferro alloys. They are monophase type. Three-phase furnaces rated, respectively, 3500 and 5000 KW are used here for refining of cast iron and foundry work. They employ Soederberg continuous electrodes. JDG(17)

Furnaces and Mills at Apollo Steel Co. A. L. HOLLINGER (Surface Combustion Co.). *Blast Furnace & Steel Plant*, Vol. 18, Oct. 1930, pages 1607–1610.
Description of equipment in the plant at Apollo, Pa. Comprises 4 gas-fired, automatic, walking-beam type pair furnaces, 3 pack furnaces of similar design and construction, normalizing furnace, 11 box-annealing furnaces and galvanizing furnaces. MS(17)

Steel Foundry Centralizes Operations. NORMAN F. HINDLE *Iron Trade Review*, Vol. 86, Jan. 16, 1930, pages 37–41, 92.
Describes operations of the Farrell-Cheek Steel Foundry Co., Sandusky, Ohio. MS(17)

Metallurgical Laboratories. CARLE R. HAYWARD. *Mining & Metallurgy*, Vol. 11, May 1930, pages 252–254.
Presented before a session of the committee on engineering education, American Institute of Mining Engineers, Feb. 1930. Gives the general aspects of college laboratory work. Describes the laboratories of the Massachusetts Institute of Technology. VSP(17)

Metallurgy for Wasps and Hornets. JOHN HAYDOCK. *American Machinist*, Vol. 73, July 31, 1930, pages 189–192.
Description of the recently completed heat treating and metallurgical departments of the Hartford plant of the Pratt and Whitney Aircraft Co. They have 6 divisions: (1) chemical laboratory and balance room; (2) physical laboratory; (3) photographic and microscopic section; (4) furnace room; (5) etching and plating room; (6) inspection department. Lists and describes location of the equipment. RHP(17)

Exemplary Adaptation of Aluminum to Construction. JUNIUS D. EDWARDS (Aluminum Company of America). *Chemical & Metallurgical Engineering*, Vol. 37, July 1930, pages 428–429.
Describes the uses to which Al and its alloys are put in the research laboratories of the Aluminum Company of America. See article in *Metals & Alloys*, Vol. 1, Sept. 1930, pages 717–720. MS(17)

Special Equipment Speeds Output in New Steel Foundry. EDWIN F. CONE. *Iron Age*, Vol. 126, Dec. 1930, pages 1683–1687.
Describes electric steel foundry of the Lebanon Steel Foundry. VSP(17)

Electric Heat Treating of Roller Bearings Reduces Costs. E. V. BLANCHARD (Bower Roller Bearing Co.). *Iron Age*, Vol. 127, Jan. 8, 1931, pages 172–175.
Describes installation of Bower Roller Bearing Co., Detroit, for carburizing and heat treating roller bearings, cups, cones and rolls. The furnaces were built by the Electric Furnace Co., Salem, Ohio. Greater uniformity of heat treatment is obtained. Close check insures proper control during carburizing. VSP(17)

Vitreous Enameling of Stove Parts. E. F. BERRY. *Metal Cleaning & Finishing*, Vol. 2, Apr. 1930, pages 341–344.
Describes pickling, sand-blasting, and enameling procedure and the electric enameling furnace of the Mansfield Vitreous Enameling Co., Mansfield, Ohio. MS(17)

MACHINERY & SUPPLIES (18)

Rubber Coated Metal Useful in Plating Equipment. GEORGE S. HERRICK. *Iron Age*, Vol. 126, Sept. 4, 1930, pages 618–619.
A German process is employed whereby rubber is deposited on intricate metal articles electrolytically. The rubber provides a perfect insulation and prevents large loss of current in bath. Large tanks are coated by hand. Rubber coating on tanks has an adherence of about 300 lbs./in.^{2} and can withstand a temperature up to 212° F. VSP(18)

Trends in the Design of Forge Equipment. MACDONALD S. REED (Erie Foundry Co.). *Heat Treating & Forging*, Vol. 16, Jan. 1930, pages 51–52.
Reviews improvements in hammer design. MS(18)

BIBLIOGRAPHIES (19)

Literature on the Use of X-Ray. Pt. I–II. VICTOR S. POLANSKY. *Heat Treating & Forging*, Vol. 16, July 1930, pages 876–880; Aug. 1930, pages 1011–1014.
Bibliography on X-ray examination of ferrous metals and alloys confined to the literature available in the Technology Dept. of the Carnegie Library of Pittsburgh. The material has been brought up to May 1930. Arranged alphabetically by authors, the last entry being H. Lange. MS(19)

MISCELLANEOUS (20)

Modernization of Existing Steel Plants. A. L. REICHERT (Bourne-Fuller Co.). *Rolling Mill Journal*, Vol. 4, April 1930, pages 135–138.
Points out that maintenance costs can be reduced and production increased in existing steel plants by the application of such improvements as twin motor roll drives, "one way fired" soaking-pits, electrically driven soaking-pit covers, electric furnaces, anti-friction bearings, and oil-electric locomotives for yard duty. MS(20)

Study of Methods for Determining Moisture in Sand. S. H. GRAF & R. H. JOHNSON. *Proceedings American Society for Testing Materials*, Vol. 30, Part 2, 1930, pages 578–590.
This deals with the determination of moisture in sand for concrete, and does not state whether the conclusions apply to molding sands. Thirteen methods were examined. To determine total moisture, three methods, (A) oven drying, (B) distillation, (C) alcohol, are graded in the following order: For accuracy, A, B, C; for simplicity, B, A, C; for requiring minimum apparatus, C, A, B. Electrical resistance methods are inaccurate. (20)

Handling of Hot Metal. WALTER DE FRIES (William B. Pollock Co.). *Rolling Mill Journal*, Vol. 4, June 1930, pages 297–298.
Abstract of a paper read before the Association of Iron & Steel Electrical Engineers, June 16–20, 1930. MS(20)

Abrupt Deformation. (Zur Frage der sprungartigen Deformation.) N. DAWIDENKOW. *Zeitschrift für Physik*, Vol. 61, Mar. 21, 1930, pages 46–53.
A report from the Leningrad Laboratory of Engineering Physics. Suggests that the phenomena observed by Classen-Nekludowa are due, possibly, to sudden decrease in resistance to deformation after the beginning of the flow of material and to reduction in strength on account of recrystallization. (20)

Behavior of Thorium Oxide in Annealed Tungsten Wires. (Zum Verhalten des Thoroxyds in Wolframglühdrähten.) W. G. BURGERS & J. A. M. VAN LIEMPT. *Zeitschrift für anorganische und allgemeine Chemie*, Vol. 193, Oct. 10, 1930, pages 144–160.
Roentgenographic investigations shows that in unannealed drawn W wire containing ThO_2 and of poly-crystalline structure the oxide of Th is present as such. In single crystal wire the ThO_2 crystallite shows no preferential orientation. By annealing the poly-crystalline at high temperatures (above 2500° abs.) part of the ThO_2 is reduced to metallic Th. At these temperatures, there is also the possibility of incomplete reduction of ThO_2 with the formation of oxides intermediate between the metal and ThO_2. The existence of a face centered lattice with a parameter between those of ThO_2 and Th was observed, and it was also found that a lattice with varying values of parameter could be obtained by annealing superficially oxidized Th wire in vacuo for different time intervals. Accurate determinations of the lattice constructions of ThO_2 and Th were made, the following values being obtained for a: ThO_2, highly ignited and prepared from the nitrate -5.585 ± 0.001 A. U.; Th prepared by reduction of chloride with Na -5.074 ± 0.002 A. U.; Th metal prepared by thermal decomposition of the iodide -5.081 ± 0.002 A. U. (20)

Inorganic Lubricants. I. Amalgams. WILLIS A. BOUGHTON. *Journal American Chemical Society*, Vol. 52, June 1930, pages 2421–2422.
A note describing the use of amalgams as a lubricant for glass joints. The surface is silvered and then treated with Hg or with a complex amalgam. Such amalgamated surfaces are not permanent. MEH(20)

Problems of Lubrication in the Steel Plant. GEORGE M. COLBURN (Carnegie Steel Co.). *Blast Furnace & Steel Plant*, Vol. 18, March 1930, pages 454–456.
Outlines essential features of good lubrication of steel-mill equipment from a practical point of view. MS(20)

Manufacture of Seamless Steel Tubing. J. W. URQUHART. *Blast Furnace & Steel Plant*, Vol. 18, April 1930, pages 627–630.
Seamless tubing is finding many uses in Great Britain and the production exceeds that of many other countries. Trend is toward the use of high C and alloy steels as well as low C steel. Describes processes involved in the manufacture of tubes. MS(20)

A Rapid Method for Sorting Aluminium Scrap. ROBERT J. ANDERSON. *Metal Industry*, London, Vol. 37, July 11, 1930, pages 27–29.
Describes a device to facilitate hand sorting of mixed scrap containing pure Al and various grades of alloy scrap. Method of sorting is based on the measurement of the thermal electromotive force of a couple, one element of which is Al and the other an Al alloy. Equipment was designed especially for production sorting in secondary Al work. Particularly adaptable in sorting and testing, and to distinguish so-called 2S and 3S sheets. VSP(20)

Diversification Aids Malleable. E. K. SMITH & F. B. RIGGAN. *Iron Age*, Vol. 125, July 19, 1930, pages 1825–1827.
In non-ferrous field, brass and lighter alloys are making great progress. Die castings are becoming more popular. Steel castings with tensile strength from 50,000 lbs./in.^{2} to beyond 100,000 can be had. Gray iron castings with resistance to corrosion, wear, and pressure are obtainable. Boyden, Moldenke, Schwartz, and Bean are responsible for progress made in malleable. Possibilities for further research. Greater technical flexibility is needed by industry at large. VSP(20)

Briquetting Cast Iron Scrap for Melting. L. M. JORDAN. *Heat Treating & Forging*, Vol. 16, April 1930, pages 470, 483.
Dodge Brothers reclaim cast-iron boring and turnings for use in the cupola by compressing the loose chips with hydraulic pressure into briquets. Pressure used is approximately 50,000 lbs./in.^{2} Briquets are $3^1/_2$ in long and 4 in. in diameter and weigh from 8–10 lbs. Average density is about 80% of that of the solid iron from which they were turned. Packard Motor Car Co. has a similar machine but uses air instead of hydraulic pressure. MS(20)

What Does Industry Want in the Training of Metallurgists? STEPHEN L. GOODALE (Univ. of Pittsburgh). *Mining & Metallurgy*, Vol. 11, May 1930, pages 248–249.

Read before committee on engineering education, American Institute of Mining and Metallurgical Engineers, New York, Feb. 1930. College training should cover mathematics, physics, mechanics, electricity, chemistry and physical chemistry. Report of several industrial representatives at the University of Pittsburgh was that college students should work in industry at periods during their college course. Education is governed by the general law of demand and supply. Industry asks that students' courses include thorough training in sciences of some cultural study, some business law and finance and all the metallurgy possible. VSP(20)

Electrolytic Iron from Sulphide Ores. T. D. YENSEN (Westinghouse Electric & Mfg. Co.). *Mining & Metallurgy*, Vol. 11, April 1930, pages 212–213.

Discussion of Technical Publication of American Institute of Mining and Metallurgical Engineers, No. 268 by Robert D. Pike, and others. See *Metals & Alloys*, Vol. 1, May 1930, page 527. VSP(20)

Recovery of Fine Gold and Fine Silver from Gold and Silver Scrap. (Gewinnung von Feingold und Feinsilber aus Altgold- und Altsilberlegierungen.) ERNST ROSENBAUM. *Chemiker-Zeitung*, Vol. 54, Sept. 24, 1930, pages 743–744.

Au is mixed with at least 2.5 its weight of Ag, the alloys melted together and poured into water to form small particles. These are boiled from 2 to 5 times in HNO_3, depending on the proportion of Ag, to dissolve the Ag. Au is washed and remelted. Ag is precipitated with HCl and reduced with NaOH and formaldehyde. If the filings contain Pt and Cu, the Ag and Cu are dissolved in HNO_3, filtered off, and the Pt and Au are dissolved in a small quantity of HCl and HNO_3. This solution is evaporated until syrupy, diluted with H_2O and Pt is precipitated by addition of alcohol and NH_4Cl After filtering it is dried, removed from the paper and carefully ignited. Au is precipitated in the filtrate by treatment with SO_2 or $NaHSO_3$. It is filtered, dried and ignited at a low temperature to avoid loss in weight. CEM(20)

FOUNDRY PRACTICE & APPLIANCES (22)

Casting & Cleaning Technique in the Non-Ferrous Foundry (Die Giess- und Putztechnik in der Metallgiesserei). E. BECKER. No. 13 of H. Hermanns' Series on Works' Practice of Iron, Steel and Non-Ferrous Foundries. Wilhelm Knapp, Halle a. d. Saale, 1931. Paper, $6^1/_4 \times 9^1/_4$ inches, 68 pages. Price 5.50 RM.

Elementary discussion of gating methods, effect of heavy sections ajoining light ones, risers, etc., shanks and ladles. Brief comment on casting rod brass bearings into iron or steel backs, or around iron or steel shafts, babbitting bearings, casting in permanent molds, casting ingots for rolling, making die castings, and centrifugal casting.

Sprue cutters, cutoff saws, bandsaws, tumbling barrels, grinding wheels, sand blasts, pickling methods and filling defects by welding or metal spraying are all discussed.

The discussion on all topics is decidedly brief. The pamphlet might serve as an introduction to the subjects in a high school manual training course.—H. W. Gillett (22)-B-

Magnesium Alloy Castings. E. PLAYER. *Metallurgia*, Vol. 3, Dec. 1930, pages 46, 52.

Elektron (3% Zn, 4% Al, 0.35 Mn, balance Mg) has a specific gravity of 1.82 and a tensile strength of 9–11 tons/in.^{2} A special flux, with a $MgCl_2$ base is recommended for melting. In making sand castings, the Mg reacts with the moisture in the molds even in dry-sand molds. This difficulty can be overcome by means of a patented process in which S and boric acid are mixed with the sand. The metal causes the S to volatilize and protect the mold. Molding practice is in general similar to practice with Al. JLG(22)

Overcoming Alloy Ingot Troubles in the Brass Foundry. WILLIAM E. PAULSON. *Metal Industry*, N. Y., Vol. 28, July 1930, page 336.

From a paper read at the Cleveland meeting of the American Foundrymen's Association, May 12–16, 1930. A purely non-technical discussion of the difficulties experienced in producing non-ferrous castings using alloy ingots. See also *Metals & Alloys*, Vol. 1, Sept. 1930, page 743. VSP(22)

Oil-Sand Cores for Non-Ferrous Castings. N. F. BUDGEN. *Metal Industry*, N. Y., Vol. 28, Aug. 1930, pages 370–371; Sept. 1930, pages 417–419.

Oil sand cores must be waterproof, must have strong green bond, sand grains must be readily wetted by core oil, core must be exceptionally strong and give off very little gas. Advantages and disadvantages of oil-sand cores. Materials and mixtures employed. Prevention of objectionable odors from cores or oil-sand molds is accomplished by baking at suitable temperature, about 250° C. Mortar mill method of mixing oil-sand is preferred. Factors affecting properties of finished cores are time of baking, temperature and atmospheric conditions in the oven, drying stove construction, and moisture absorption after drying. Gives tables showing average transverse strength of cores before and after placing in green sand molds. The use of old oil-sand cores is not generally regarded as very satisfactory. VSP(22)

Aluminum Pan Needs Many Runners. JOSEPH MCGINNIS. *Foundry*, Vol. 58, May 15, 1930, page 60.

Describes method of casting Al vacuum pan 8 ft. 4 in. wide, 12 ft. 6 in. long and $^1/_4$ in. thick. The greatest problem is to keep the castings from cracking. VSP(22)

American Brass Foundry Practice. Pt. VII. Laying Out the Patterns. CHARLES VICKERS. *Foundry*, Vol. 58, April 15, 1930, pages 69–71, 83–84.

Poor patterns, or poorly arranged patterns, whether on plate or gate, produce more costly castings than well arranged and well designed patterns. Gating of small castings vary greatly. High leakage loss. In case of heavy valves having flanged ends, it is often necessary to put risers on top of flanges. Leakage is caused usually by hard cracks between body and flange. There is considerable difference in alloys used, as some shrink more than others. Fe causes trouble. Pattern-makers should know something about solidification. Ni is added to castings carrying steam pressure. Small amounts of P will control leakage. VSP(22)

The Fundamentals of Brass Foundry Practice. Parts 24 & 25. R. R CLARKE. *Metal Industry*, N. Y., Vol. 28, Aug. 1930, pages 374–375; Oct. 1930, pages 466–467.

On the affinities of some metals for each other depends much of the possibilities of properly alloying metals. Defines and gives examples of mechanical and chemical mixtures. The 3 factors affecting the homogeneity of mechanical union in castings are: specific gravity, melting temperature and mechanical manipulation. In chemical union the metals are combined and maintain that state in remelting and casting without further mechanical aid. In chemical union the properties of the alloys often change radically from those of individual metals. In mechanical union, the properties of the combined metals show an average of their component metals in ratio of the quantities. Part 25 describes basic laws which control the melting and casting of metals and their applications to practical foundry work. Primary effect of Sn and Cu is to harden, to reduce malleability, toughness and ductility and to tend toward brittleness with its advancing ratios. Effect of Zn on Cu is to toughen and cheapen it; the coloring effect on Cu is to "yellow" it. Effect of Pb on Cu is to soften it. It renders mixture anti-frictional. Cu-Sn-Pb alloys are used mainly for bearing purposes. VSP(22)

FURNACES & FUELS (23)

The Heating of Mixers with Blast Furnace Gas. (Ueber die Mischerbeheizung mit Hochofengas.) K. D'HUART. *Stahl und Eisen*, Vol. 50, May 1, 1930, pages 585–588.

The paper describes the various types of heating mixers with blast furnace gas. A new method of heating mixers uses 2 regenerator chambers for heating up the blast furnace gas. This new heating method requires a minimum of space, is simple in construction and has low first cost. GN(23)

Annealing Pressed Steel Hubs. W. M. HEPBURN. *Fuels & Furnaces*, Vol. 8, March 1930, pages 363–364.

At the plant of the Wire Wheel Corporation of America, parts for wire wheels are annealed at 1400° F. in a continuous, counter-flow, pusher type, gas-fired furnace. It is $43^1/_2$ ft. long, $8^1/_2$ ft. wide, and 3 ft. high. Hot zone is 20 ft. long and the heat interchange zones are $11^1/_2$ ft. long. MS(23)

Regenerative-Gas Constant Current Furnaces with Two Chambers. (Zweikammer-Regenerativgas-Gleichstromöfen.) H. FEY. *Stahl und Eisen*, Vol. 50, Feb. 20, 1930, pages 223–229.

A new type of regenerative continuous furnace for heating billets is illustrated and described, after reviewing the development of the furnace type with return flame. In the new furnace, the air current coming from one of the 2 chambers is divided; one part enters the furnace direct, passing through the furnace in one direction, the other part of the air is used for the combustion of cold gas entering the flue direct, in front of the regenerative chambers. The resulting flame heats the regenerative chambers direct. 3 different types of this new furnace are described. The heat efficiency of the chambers amounts to 85%. The furnace produces over the whole length uniformly heated billets. GN(23)

Appliances for Heating Wheel Tires. (Vorrichtungen zum Anwärmen von Radreifen.) H. FEY. *Stahl und Eisen*, Vol. 50, Jan. 30, 1930, pages 131–133.

A new heating device for wheel tires built by the Lindemann Company at Düsseldorf, Germany, is illustrated and described. This new furnace, provided with burners in a segmental arrangement, is distinguished by its simplicity and high output. The gas consumption amounts to 3 m.^{3} of gas for every m. in diameter of the tire, the heating time to 12–15 min. Since the segmental burners can be adjusted on the ground plate, there are no restrictions as to the size of the tires to be heated. GN(23)

High-Frequency Steel Furnaces. D. F. CAMPBELL. *Heat Treating & Forging*, Vol. 16, Oct. 1930, pages 1273–1276; *Engineer*, Vol. 150, Oct. 3, 1930, page 362.

An abstract of a paper read before the Iron and Steel Institute, Prague, Sept. 16, 1930. See *Metals & Alloys*, Vol. 2, Jan. 1931, page 16. LFM(23)

The Heating Up of Open-Hearth Furnaces and Casting Ladles. (Das Anheizen von Siemens-Martin-Oefen und Giesspfannen.) G. BULLE. *Stahl und Eisen*, Vol. 50, Feb. 13, 1930, pages 193–205.

Report 180 of the Steel Mill Committee of the Verein deutscher Eisenhüttenleute. The paper gives information on methods of heating up open-hearth furnaces, ladles and stoppers as collected by a questionnaire issued to all German steel mills. The methods of heating up open-hearth furnaces are mostly rather rough; more modern methods are used in heating up ladles and stoppers. In general, the heat required to heat up a newly lined open hearth furnace varies, according to size, from 200 to 1000 $\times$ 10^6 kg.-cal; the heat for heating up ladles varies from 1 to 10 $\times$ 10^6 kg.-cal.; for stoppers from 50,000 to 100,000 kg.-cal. These data, however, do not seem to be very accurate since the heating up is, in many cases, not very carefully done. No doubt improvements are possible in many cases. GN(23)

Testing and Rating Fuel Fired Industrial Furnaces. Parts XIV–XVI. W. C. BUELL, JR. *Fuels & Furnaces*, Vol. 8, April 1930, pages 517–518; May 1930, pages 659–662; June 1930, pages 809–810.

Discusses measurement of the heat lost in furnace cooling water. Presents curves showing the thermal content of commercial Fe or steel, and pure Al, Cu, and Zn at various temperatures, and Oberhoffer's results for pure Fe. Curves are also shown for the heating time of steel 2 in. in cross-section to various final temperatures. The heating time for Fe is about 36% longer than for steel. The heat of the mass is taken as the mean of the outer and the inner (estimated) temperatures. Gives some general comments on measuring and recording temperature, but does not go into details regarding instruments. Illustrates test data sheets. MS(23)

High-Speed Steel Treated in a Special Electric Furnace. E. N. BROOKINGS (Jones & Lawson Machine Co.). *Iron Age*, Vol. 126, Nov. 6, 1930, pages 1295–1298, 1360.

Gives details of construction of the electric furnace used by Jones & Lawson Machine Co. VSP(23)

Factors Governing Fuel Efficiency of Enameling Furnaces. VICTOR J. AZBE. *Fuels & Furnaces*, Vol. 8, Feb. 1930, pages 207–210, 219–220.

Discussion of various factors entering into design, and operation. Excess air and steam should be particularly avoided. Operation should be with as high furnace and as low muffle temperatures as possible. Muffles should be open if possible. Muffle material should have high heat transfer. Furnace should be operated with minimum of draft. Gas flow must be easily controlled and muffles heat uniformly. MS(23)

A Valve Operated Coreless Induction Furnace for High Temperature Research. FRANK ADCOCK. *Transactions Faraday Society*, Vol. 26, Sept. 1930, pages 544–560.

A very complete description, accompanied by numerous diagrams (6) and pictures (3) of a valve operated induction furnace the power supply for which is derived from a transformer converting three-phase current at 3000 v. to single-phase current at 220 v. The efficiency of conversion of alternating into oscillatory energy is discussed, as are also details of technique, as, e. g., difficulties: (1) with the fusion of magnetic materials; (2) due to glow discharges; (3) due to the distillation of metals during melting; and (4) with charges of small pieces and formation of "bridges." Examples of the application of the furnace to high temperature investigations are given. The article is accompanied by 15 illustrations and 1 table. OWE(23)

Open-Hearth Furnace of the Laclede Steel Co. CHARLES LONGENECKER. *Blast Furnace & Steel Plant*, Vol. 18, June 1930, pages 971–973.

Describes a 100-ton, oil-fired, automatically controlled furnace. Both furnace and regenerator walls are encased in steel plates to prevent infiltration of air. Air enters regenerators at the side and bottom. Furnace roof is straight. Furnace is charged with cold metal which is melted with an expenditure of about 3,400,000 B. t. u. Yield averages 93%. Due to the melting condition, the charge contains 20% less pig-iron, than is customary. Melting rate will average 10 tons/hr. An average of 27 gallon of 8°–12° Bé oil is burned for each ton of ingots produced. MS(23)

Design and Operation, Gas-Fired Furnaces. C. M. WALTER. *Heat Treating & Forging*, Vol. 16, Feb. 1930, pages 240–242.

Paper read before a joint meeting of the Birmingham Section and the Chemical Engineering group of the Society of Chemical Industry, and published in *Chemistry & Industry*, Vol. 48, Oct. 4, 1929, pages 954–961. MS(23)

Gas vs. Electricity for Industrial Heating. *Iron & Coal Trades Review*, Vol. 121, July 4, 1930, page 3.

Abstract of paper by Sir Robert Hadfield and R. J. Sarjant on "Relative Places of Gas and Electricity in Industrial heating," presented before the Second World Power Conference at Berlin. Use depends largely on availability and economic value. Coke oven gas and producer gas are discussed. The later is better suited for regular loads. Gas furnaces, in general, are cheaper in fuel cost but electricity gives higher thermal efficiency. Operation costs generally favor the electric furnace. Gas furnaces are more flexible. For short-cycle or intermittent operations in batch type furnaces, gas is more economical; for long soaking treatment under either batch or continuous conditions, electric furnaces are more suitable. Electric furnaces permit accurate and automatic control. RHP(23)

Use of Blast-Furnace and Coke-Oven Gas in German Iron and Steel Works. *Iron & Coal Trades Review*, Vol. 121; Aug. 15, 1930, pages 220–221; Aug. 22, 1930, pages 256–257.

Abridged from *Stahl und Eisen*. RHP(23)

Heat Transfer in Regenerative Systems. George V. Slottman (Massachusetts Institute of Technology). *Blast Furnace & Steel Plant*, Vol. 18, March 1930, pages 449–452; April 1930, pages 624–626; Sept. 1930, pages 1469–1470.

Develops simplified formulae for the approximate design of open-hearth furnace regenerators. Shows that rate of heat transfer is determined by the gas velocity in the flues. With a given flue size, the preheat is determined by the height of the regenerator, the cross-sectional area of the checker having little influence, except in determining pressure drop. Preheat temperature is governed by the height of the regenerator, the size of flue and the ratio of volume of waste gas to volume of air. Special brick shapes increase the rate of heat transfer, the heating surface, or provide against plugging. Average brick temperature varies with the inlet gas temperature, and the ratio of the volume of waste gas to the volume of air. An optimum time of cycle exists for each regenerator, which must be determined experimentally. Applies the formulae developed to practical design of regenerators. MS(23)

Recuperators for Super-Temperatures. B. W. Stromberg (Carborundum Company). *Blast Furnace & Steel Plant*, Vol. 18, March 1930, pages 482–483.

Refractory rods or "corebusters" are placed along the axis of the tubes of Si-C tube recuperators. The rods are supported from the bottom of the tubes by means of a few legs. Their use results in a substantial increase in the inside convection area of the tubes and in an increase in the efficiency of the rate of heat transfer. Several tests indicated that the increase in heat recovered with "corebusters" amounts to about 45%. MS(23)

Automatic Furnace Simplifies Annealing. W. M. Hepburn (Surface Combustion Co.). *Heat Treating & Forging*, Vol. 16, March 1930, pages 374–375, 382.

Mullins Mfg. Co., Salem, Ohio, has installed a gas-fired counterflow, conveyor-type oven, 53 ft. long for annealing stampings. Furnace is divided into preheating, hot, and cooling zones. The hot zone is 17 ft. long and temperature is maintained at 1650° F. Heat cycle is 4 min. in preheating zone, 6 min. in the hot zone, and 4 min. in the cooling zone. MS(23)

Refractory Torches for Local Heating. F. E. Harris. *Heat Treating & Forging*, Vol. 16, Jan. 1930, pages 97–99.

Describes the design of gas-air torches for local heating of metal parts, and discusses the underlying principles. General design consists of a mixture nozzle and a refractory-lines combustion tip. The latter has flaring walls. Describes application to annealing portions of a radiator shell and to local annealing of a gear blank. Local temperatures of 1500° F., in 6–8 sec. are easily attained. MS(23)

Butane Burned in Heat Treating Furnace. Charles Longenecker. *Heat Treating & Forging*, Vol. 16, Jan. 1930, pages 100–102.

Chrysler plant in Detroit uses C_4H_{10} as fuel for hardening and drawing furnaces. Axle shafts are heated to 1550° F. in the former and to 880° F. in the latter. Tabulates properties of the gas, and describes method of unloading the liquified product from tank cars, means of storage, and distribution of fuel in the plant. Some of the advantages of using C_4H_{10} are constant heat value and pressure; accurate temperature control; low percentages of rejections; great hardness; easy and economical distribution; scaling of steel is negligible; and safety is promoted. MS(23)

Heat Treatment of Ball Bearing Races. W. B. Haag (Marlin-Rockwell Corp.) & Wirt S. Scott (Westinghouse Electric & Mfg. Co.). *Heat Treating & Forging*, Vol. 16, Jan. 1930, pages 64–69.

The Marlin-Rockwell Corp. replaced oil-fired salt-bath hardening furnaces and gas-fired oil-tempering baths with 3 new oil-fired, semi-muffle, underfired box type furnaces, one rotary-hearth electric furnace, and one electrically-heated oil-tempering bath. The electric furnace accomplished a saving in labor, better quality, better working conditions, increased production, saving in ventilating equipment, saving in maintenance, and improvement in shop appearance. The estimated total net savings of the rotary-hearth electric furnace over the oil-fired salt-bath furnaces amounted to $2513.00 per month on a production basis of 150,000 lbs. per month. The savings over the hearth-type oil-fired furnaces amounted to $770.00 per month. Cost and savings are tabulated. MS(23)

Heating by Electricity Found Profitable. Francis W. Rowe. *Heat Treating & Forging*, Vol. 16, May 1930, pages 643–648.

Works with which author is associated manufacture gears and gear units. Present furnace equipment consists of three 25 kw. reheating furnaces and a 40 kw., a 200 kw., and two 100 kw. carburizing furnaces. These replaced coke-fired muffle-type carburizing furnaces, semi-muffle type carburizing furnaces with coke-fired producers built in, and reheating furnaces fired by town gas and producer gas. Presents tables giving cost of energy for each of the furnaces. In no case is the cost for fuel alone higher with the electric furnaces than was the case with the old furnaces. Use of electric furnaces has resulted in saving in labor, improved working conditions, and improved quality of output. MS(23)

New Type of Pair Heating Furnace. T. J. Ess (Central Alloy Steel Corp.). *Heat Treating & Forging*, Vol. 16, May 1930, pages 648–650; *Blast Furnace & Steel Plant*, Vol. 18, July 1930, pages 1137–1138, 1142.

Described the McCann conveyor-hearth furnace for pair heating. It is encased in a shell of structural plates and shapes with all openings amply protected with cast-iron plates and panels. Conveyor consists of a heavy steel frame extending under the charging platform and furnace, carried on a series of rollers. Cr-Ni alloy posts are mounted on frame bottom, carrying alloy cross rails and conveyor rails inside of the furnace. Rollers are connected through a series of pull-rods and bell-cranks to the duplex drive mounted under the charging platform and consisting of a motor-driven constant-speed driving-shaft, a lifting-shaft, and a traversing shaft, all interconnected with specially designed gearing. Furnace is approximately 25 ft. long × 6 ft. 9 in. wide, and is well insulated. Burner equipment consists of 14 McKee high-pressure gas-injector burners, using natural gas at pressures up to 25 lbs./in.^{2} Furnace is divided into 2 zones, temperature of each being independently controlled. Including gas used for warming up furnace after week-end shutdown, average gas consumption is 1107 cu. ft./net ton of metal charged. MS(23)

Scholes-Incandescent Patent Plate-Heating Furnace at Consett Works Durham. *Iron & Coal Trades Review*, Vol. 121, July 4, 1930, pages 1–2.

Describes a furnace designed to treat plate uniformly throughout at the same time maintaining straightness. Main points of construction and operation are: (1) load in charging or discharging is not carried on the furnace hearth; (2) furnace roller gear remains in the hot zone of furnace for a minimum of time; (3) material is not marked or affected by skid bars; (4) burners are arranged alternately on either side of furnace to give uniform heating; (5) gas and air supplied under pressure; (6) preheating is done by passing both gas and air through mild steel tubes under the furnace hearth; (7) flue arrangement avoids explosions; (8) furnace is easily lit up. Gives power consumed, analysis of gas and temperature. RHP(23)

Normalizing Furnace for Sheet Steel. J. R. Miller. *Heat Treating & Forging*, Vol. 16, April 1930, pages 507–508.

Central Alloy Steel Corp. has installed in its Canton, Ohio, plant a natural-gas-fired walking-beam normalizing furnace. Furnace proper is 100 ft. long and is divided into a 10-ft. preheat zone, a 30-ft. first heating zone, a 20-ft. first cooling zone, a 30-ft. second heating zone, and a 10-ft. final cooling zone. It is wide enough to accommodate sheets up to 108 in. wide. It will treat 8 tons of sheets per hr. Gas consumption is about 1300 cu. ft. of natural gas per gross ton of material heated. Burners are arranged for combined over- and under-firing. Furnace is designed to work satisfactorily at any temperature up to a maximum of 1850° F. Speed of stock through furnace can be regulated from $2^1/_2$–10 ft./min. depending upon the gage of the sheet and other variables. MS(23)

Electric Heat and Heat Treating Alloy Steel. Thomas W. Hardy (Dept. of Mines, Canada). *Heat Treating & Forging*, Vol. 16, Jan. 1930, pages 53–58.

Electric heating furnaces have certain advantages which more than outweigh the higher initial cost as compared with that of fuel-fired furnaces, and the higher cost of electricity over fuel on a strictly B. t. u. basis. These are lower labor and maintenance costs, more efficient utilization of energy, and the ability to positively reproduce established time-temperature cycles. Car-bottom type of furnace is most satisfactory for miscellaneous short cycle annealing. Pit type is most suitable for annealing of such refractory steels has high C-high Cr steel, requiring time cycles as long as 80 hrs. or more. Continuous furnaces are best for normalizing. A double-end type has been designed for the heat treatment of bars in mill lengths. For the annealing of coiled rods or wire, a circular pit furnace has been found to be very satisfactory. Describes some installations of these types of electric furnaces. MS(23)

Electrical Equipment for Heat Treating. C. L. Fisher (Westinghouse Electric & Mfg. Co.). *Heat Treating & Forging*, Vol. 16, June 1930, pages 775–777.

Illustrated description of the furnaces used by the Westinghouse Electric & Manufacturing Company in the heat treatment of tools. All heat treating equipment is electrically controlled. All oil, Pb, salt and salt tempering units, and some oven-type furnaces are electrically heated. Some of the oven-type furnaces are gas-heated. Gas at 15 lbs. pressure is used, as it can be more readily controlled electrically than on air blast used with gas at ordinary pressure. MS(23)

Economical Operation Obtained with New Commercial Gas. George J. Hales (General Electric Co.). *Fuels & Furnaces*, Vol. 8, Aug. 1930, pages 1117–1118.

General Electric Co. has developed a gas, Electrolene, for use in many processes where pure H is not required. It is the product derived from dissociating a hydrocarbon gas, usually with the addition of steam. It contains approximately 75% H, 20% CO, and small quantities of other gases, N being the most prominent. Input gas can be any gas containing sufficient hydrocarbons to make the process economical. Producers are comparatively inexpensive to install. The new gas is used as a non-oxidizing atmosphere in furnaces for Cu brazing and as neutral atmosphere for annealing. By varying the CH_4 content, a gas neutral to any C steels can be obtained which will prevent decarburization of the metal. MS(23)

Automatic Reversing Open Hearth Furnaces. Bradley. *Fuels & Furnaces*, Vol. 8, July 1930, pages 979–980, 986.

From paper read before the Association of Iron & Steel Electrical Engineers, June 16–20, 1930. MS(23)

Heat Requirements for Core Baking Ovens. H. L. Campbell (University of Michigan). *Fuels & Furnaces*, Vol. 8, July 1930, pages 955–956.

Most favorable temperature for baking cores containing only water-soluble binders and those bonded with pitch and rosin is 350° F. Oil binders require an oven atmosphere containing fresh air. A minimum volume of 1000 in.^{3} of air is necessary to develop maximum strength in one lb. cores containing raw linseed oil in the proportion of 2% of the volume of the core sand. Baking for 90 min. at 425° F. produces maximum strength in 1 in. thick oil-sand cores. Best temperature for cores containing mixtures of water-soluble binders and oil is 400° F. Both time and temperature must be controlled accurately to produce maximum strength. Industrial gas is especially suited for baking cores. MS(23)

High Frequency Induction Furnaces Used in Melting Tool Steels. *Fuels & Furnaces*, Vol. 8, July 1930, pages 951–952.

Firth-Sterling Steel Co., McKeesport, Pa., has 2 Ajax-Northrup furnaces of 500 and 1000 lbs. capacity, respectively. Melting is done in MgO crucibles placed inside a lining composed of a dry powdered refractory such as chrome ore or electrically fused MgO. Cu cooling coil acts as the primary, the secondary being the melt itself. Single phase current at 800 volts and a frequency of 960 cycles is used. The furnace is rated at 150 kw. and requires about 50 min. to melt a 500 lbs. charge. MS(23)

Brass Strip Annealed in Oil Fires Furnace. *Fuels & Furnaces*, Vol. 8, Aug. 1930, pages 1065–1066.

Dallas Brass and Copper Co., Chicago, has installed a side-fired furnace with 12 oil burners and automatic temperature control. Slabs of rolled metal are carried through the furnace in alloy pans on roller conveyors. Stock withdrawn from the furnace is quenched by cold water spray. Operating temperature of the furnace is 1150°–1450° F., depending on the gage and composition of the metal. One pan enters the furnace about every 2 or $2^1/_2$ hrs. MS(23)

High Frequency Electric Furnaces and Their Practical Characteristics. (Les four electriques a haute frequence et leur characteristiques pratiques.) *Journal du Four Electrique*, Vol. 39, Sept. 1930, pages 336–339.

Brief description of better known installation of Ajax-Northrup high frequency furnaces in the United States. JDG(23)

The Utilization of Town's Gas as a Fuel in Heat Treatment Furnaces. C. M. Walter. *Metal Industry*, London, Vol. 36, June 20, 1930, pages 651–654; June 27, 1930, pages 677–682; *Journal Institute of Fuel*, Vol. 3, July 1930, pages 408–427.

Paper read before Institute of Fuels, May 14, 1930. Deals with a special application of town's gas as a fuel to a particular industrial operation and the various stages of development in the design of inflame type gas-furnace. Low calorific value gas is often associated with high calorific intensity, due to high % of CO. Gives operating costs in terms of efficiency. Development in the design of gas-heated oven type furnaces. Specifications for recuperator oven furnace is given. Includes results of furnace tests and numerous tables and diagrams. VSP(23)

REFRACTORIES & FURNACE MATERIALS (24)

Bottoms in Forging Furnaces. *Heat Treating & Forging*, Vol. 16, May 1930, page 658. Condensed in *Fuels & Furnaces*, Vol. 8, June 1930, page 858.

Abstract of survey made by A. C. Nielsen Co., Rockford Drop Forge Co. in replacing the ordinary fire-brick construction formerly used in their forging furnaces with monolithic bottoms made of plastic chrome ore. A complete elimination of slagging and a saving of 57% in bottom costs is claimed. MS(24)

Refractories and Their Applications. MARTIN J. CONWAY (Lukens Steel Co.). *Heat Treating & Forging*, Vol. 16, June 1930, pages 732–734; *Blast Furnace & Steel Plant*, Vol. 18, June 1930, pages 1001–1003.

In practice, term "refractory" means not only resistance to high temperatures, but includes also resistance to disintegration by other causes, such as abrasive action of the contents of the furnaces, dust in flue gases, corrosion by gases or other substances, and sudden changes in temperature. Discusses permanent expansion of fire-brick. Greatest contribution to furnace design and refractory life in recent years has been the substitution of suspended refractory for the conventional sprung arch and the adaptation of this type of construction to the side walls as well as the roofs and arches of all types of industrial and boiler furnaces. Discusses disadvantages of the sprung arch and advantages of the flat arch. MS(24)

Interlocking Suspended Furnace Arch. W. J. SHANE. *Blast Furnace & Steel Plant*, Vol. 18, June 1930, pages 1013–1014.

Describes arch patented by L. S. Longenecker. Makes use of an interlocking title, which has on one of its faces an inverted V-shaped tongue about 3/8 in. thick, and on the opposite face a similarly shaped groove. Tongue and groove furnish a positive interlock which will hold any broken inner tile ends from dropping out. Each tile is equipped with a modified U-casting hanger having a T-end which fits into the T-slot of the tile, located directly above the tonue. The short leg of the U-casting makes contact on the groove side. The hanger serves as a handle to lift the tile. The tiles are suspended directly from the lower flange of an I-beam in bundles of 12, by means of the special "Thumb and Finger" type beam casting. MS(24)

Furnace Insulation in the Steel Mill. E. A. PHOENIX (Johns-Manville Corp.). *Blast Furnace & Steel Plant*, Vol. 18, June 1930, pages 1005–1010.

Insulating materials for high temperatures must have low thermal conductivity and high degree of refractoriness. Diatomaceous silica forms the base for almost every high temperature insulating material in use today, because it possesses these properties. It is produced in a wide variety of forms. Illustrates and describes methods of insulating hot-blast stoves, blast-furnace stacks, open-hearth plant, soaking-pits, and heating, annealing, and heat-treating furnace. Includes curves of comparative heat losses. MS(24)

GASES IN METALS (25)

Experiments on the Influence of Gases on the Soundness of Copper Ingots. N. P. ALLEN. *Journal of the Institute of Metals*, Vol. 43, 1930, pages 81–124, 142–162.

Gas Removal and Grain Refinement of Aluminium Alloys. W. ROSENHAIN, J. D. GROGAN & T. H. SCHOFIELD. *Engineer*, Vol. 150, Sept. 19, 1930, pages 317–318.

Abstract of paper read before the Institute of Metals, Sept. 10, 1930. See *Metals & Alloys*, Vol. 1, Nov. 1930, page 856. LFM(25)

EFFECT OF ELEMENTS ON METALS & ALLOYS (27)

Arsenic in Soft Steel. (Arsen im Flusstahl.) O. BAUER. *Mitteilungen der deutschen Materialprüfungsanstalten*, Sonderheft 13, 1930, pages 58–66; *Mitteilungen Verein Grosskesselbesitzer*, No. 23, 1929, pages 3–10.

English, American and German sheet analyzed at the Staatlichen Materialprüfungsamt showed from 0.02–0.095% As, mostly between 0.035% and 0.05% As. No sample tested was arsenic-free. Soft steel plates of 0.06–0.09% C, 0.36–0.41% Mn, 0.03–0.11% S, 0.01–0.09% P and 0.04–0.11% As, with only traces of Si, Cu, Cr, Ni and Co, were specially made up and tested. The samples were in 4 groups: (a) 0.03–0.04% S, 0.015% P with 0.05–0.09% As; (b) 0.11–0.14% S, 0.015–0.025% P with 0.04–0.11% As; (c) 0.10% S, 0.03–0.08% P with 0.04 to 0.075% As; and (d) 0.04–0.05% S, 0.085–0.095% P, with 0.045–0.11% As. There were 3 steels in each group. Macroetching with copper ammonium chloride for segregation showed this to be due to P, not to As. Microscopic examination showed no change in structure ascribable to As. Critical point determinations showed no effect due to As. Static tensile tests showed the whole series to vary only from 34,000 to 40,500 lbs./in.^{2} yield point, 51,000 to 58,000 lbs./in.^{2} tensile strength, 23–32% elongation in 8", 56–68% reduction of area, whether tested longitudinally or transversely. Some slight effect of phosphorus was discernable, but no effect of arsenic could be traced. Charpy impact tests (drilled notch) in the as rolled and annealed conditions on longitudinal and transverse bars ranged from 14.5 to 5 mkg./cm.^{2} The transverse bars gave lower values than the longitudinal in the case of the steels higher in sulphur. High phosphorus steels gave low impact tests. After giving due regard to the effect of P and S in lowering the impact resistance, there was some evidence that their deleterious effect is somewhat increased by the presence of As. Impact tests were also made at −5°, 20°, 50°, 100°, 200°, 250°, 300°, 400°, and 500° C., on transverse specimens of the 2 steels of each of the 4 groups highest and lowest in As. All fell off in impact strength above 250° C., and all showed an appreciable decrease at −5° C. as compared with room temperature. The general trend indicates again that As has an embrittling influence. The effect of P was not so noticeable at the higher temperatures, while that of S was more marked than at room temperature. Transverse impact specimens that had been cold-worked by compression over the volume in which the notch was to be cut, and tested as compressed or after tempering 2 hours at 100° intervals from 100° to 900° C., were all very brittle (impact resistance only 0.7 to 2.1 mkg./cm.^{2}) up to a tempering temperature of 500° C. at which some improvement was shown. On tempering at 600–700° C. the impact values became about the same as for uncompressed annealed specimens. In the worked and tempered series the presence of As again seemed slightly to accentuate the harmful effect of P and S. It is concluded that up to 0.05% As is without material effect on any of the mechanical properties, even on impact, while larger amounts in themselves bring a rather weak harmful effect, less than that of P and S, but intensify the effect of those elements. The Effect of Phosphorus on the Strength of Admiralty Gun-Metal. H. C. DEWS. *Engineering*, Vol. 130, Sept. 26, 1930, pages 388–389.

Abstract of paper read before the Institute of Metals, Southampton Sept. 11, 1930. See *Metals & Alloys*, Vol. 1, Oct. 1930 page 789. LFM(27)

Investigations on the Influence of the Structure and the Chemical Composition of the Physical Properties of Rails. (Beitrag zu den Untersuchungen über den Einfluss des Gefüges und der chemischen Zusammensetzung auf die mechanischen Eigenschaften von Schienen.) J. E. BRAGNIN. *Stahl und Eisen*, Vol. 50, Nov. 6, 1930, pages 1589–1590.

Abstract of a paper in the Russian magazine, *Ugol i Scheleso*, Vol. 49, 1929, pages 88–122. The physical properties of 300 rails of various open-hearth steel melts were studied, including an examination of the microstructure. From the results, the authors draw the conclusion that the best values of the limit of proportionality and the limit of elasticity are obtained in rails with a C content of 0.40–0.45% and a Mn content between 1.05% and 1.10%. Heat Treating Alloy Steel Castings. Three Methods Used. Low and High Alloy Steel Castings Have Many Uses. ALBERT RYS. *Iron Age*, Vol. 125, June 19, 1930, pages 1821–1822; Aug. 28, 1930, pages 549, 598.

Abstract translation by J. M. Gaines, Jr., from *Stahl und Eisen*, Vol. 50, Apr. 3, 1930, page 423. See *Metals & Alloys*, Vol. 1, Aug. 1930, page 685. VSP(27)

Hardness of Aluminum Rich Binary Alloys in Relation to the Concentration of Added Metal. (Die Härte aluminiumreicher binärer Legierungen in Abhängigkeit von der Konzentration des Zusatzmetalles.) K. RÖTH. *Zeitschrift für anorganische und allgemeine Chemie*, Vol. 191, Aug. 2, 1930, pages 181–193.

The author finds a definite relationship between depth of penetration in Ludwik's cone method for determining hardness and the volume % of the intermetallic compound formed between Al and the added metal. This is given by the expression $h = a + \ln P_v$, where h is depth of penetration, a is the value of h for 1% by volume of the compound Al_mMe_n, and P_v is the % by volume of the compound of the added metal with $Al(Al_mMe_n)$. Data is given for binary alloys of Al with Si, Cu, Ni, Ca, Mg, Mn and Zn, and good agreement between calculated and experimentally determined values of h is obtained. (27)

Nickel-Molybdenum Steel Castings Strong at High Temperatures. LIESTMANN & SALZMANN. *Iron Age*, Vol. 126, Aug. 21, 1930, page 484.

Abstract translation of a report in *Stahl und Eisen*, No. 50, 1930. Gives a report of a systematic study of a series of cast alloys containing various small percentages of nickel and molybdenum. See *Metals & Alloys*, Vol. 1, Aug. 1930, page 685. VSP(27)

Manganese in Simple Steels. HENRY D. HIBBARD. *Fuels & Furnaces*, Vol. 8, Jan. 1930, pages 51–54; Feb. 1930, pages 217–219; March 1930, pages 391–393; April 1930, pages 541–542, 548; May 1930, pages 673–674; June 1930, pages 815–816.

Gives first a short history of the use of Mn in steel. Discusses Mn in the open-hearth charge materials, and the part played by it in working the charge; its function in eliminating oxides and regulating the boil of the bath; action of MnO; elimination of S; Mn additions to killed and rimming steels, in the ladle and in the mold; and effect of Mn in the ingot. MS(27)

A Study of Ni-V and Ni-Mo Cast Irons. (Etude sur les fontes au nickel-vanadium et au nickel-molybdene.) JEAN CHALLONSONNET. *Revue de Metallurgie*, Vol. 27, Nov. 1930, pages 573–603.

The influence of addition of Ni, V and combination of the two to carefully prepared synthetic iron (3.7 C, 0.08 Si, P traces) and to several commercial irons showed that addition of 1–2% of Ni had no influence on Curie point of cementite but lowers the point of the beginning of graphitization. It lowers both Ac and Ar points, and decreases the cementite content. 2% Ni was sufficient to cause martensitic transformation in several irons, easily discernible on dilatation curves. Addition of 0.25–0.5 % V lowers Curie point in pure Fe-C alloys to 160° and 130°, respectively, in commercial irons it lowers it to 180° and 130° not being affected by C, Si or Ni. V does not affect transformation points when present alone but counterbalances the influence of Ni when they are found together. It prevents graphitization, entirely in the case of rapid cooling, partially when Ni and Si are present. One % Ni is equivalent in this respect to 0.25% V. Being added simultaneously Ni and V counterbalance each other's effects on graphitization and cementite formation. V prevents the formation of martensite due to high Ni. In casting in stepped molds so that different rates of cooling speed could be observed it was found that V rapidly increases chilling effect while Ni lowers hardness gradient between the steps. Addition of 0.5% V increases the crushing resistance by 40 kg./mm.^{2} while 2% Ni raises it 10 kg./mm.^{2} Simultaneous addition of them gives the increase of 40 kg./mm.^{2} Their influence is greatly reduced by increased Si content. 7 references. JDG(27)

Effect of Small Additions of Copper and Nickel on the Dilation and Grain Growth of Cast Iron. (Der Einfluss kleiner Zusätze von Kupfer und Nickel auf die Wärmeausdehnung und auf das Wachsen des Gusseisens.) O. BAUER & H. SIEGLERSCHMIDT. *Mitteilungen deutscher Materialprüfungsanstalt*, Sonderheft 9, 1929, pages 63–67.

From 20° to 670° the dilation value β is not perceptibly influenced by the additions. After the decomposition of the carbide there is no permanent expansion. Small additions of Cu and Ni apparently retard the decomposition. RR(27)

Molybdenum Improves Gray Iron. J. KENT SMITH. *Foundry*, Vol. 58, June 15, 1930, pages 54–55.

Mo improves strength, density, as evidenced by grain size, absence of blow holes and hard spots, excellent machinability and minimizes foundry difficulties in cast Fe. Addition amounts to about 0.35% Mo or 7 lbs. to a short ton of clean hot cast Fe containing 3 to 3.25% C and 1.9 to 2.1% Si. Mo enters solid solution in carbonless portion of Fe and thus strengthens the Fe directly. Molybdenizing cast Fe is different from molybdenizing steel. If cupola is used as melting agent, Mo must be added in the ladle. Best method of adding Mo is by use of a Mo-Fe alloy. This alloy contains from 60–65% Mo. Tabulates data on Mo additions. VSP(27)

Tests Show Effect of Using Alloy Scrap in Making Pig Iron. E. K. SMITH & H. C. AUFDERHAAR. *Iron Age*, Vol. 126, July 17, 1930, pages 156–158.

Deals with the effects of small amounts of common alloys on characteristics of pig Fe. Describes experiments conducted. From dilatometer curves it can be noted that unalloyed pig Fe shows greatest expansion, Cr pig slight and Ti pig intermediate. From experiments following conclusions were reached: (1) alloy scrap should not be used in making pig Fe for malleable castings; (2) when alloy scrap is used for steel making or foundry pig Fe blast furnace should furnish consumer with approximate alloy contents; (3) effect of small amounts of alloys would be as cleansers and deoxidizers of pig Fe; (4) blast furnace is proper place for miscellaneous scrap, owing to its desulphurization and deoxidation; alloy scrap used in cupola would be undesirable; (5) there is little danger of any detrimental effect on castings, considering small amounts of alloys found in pig Fe. VSP(27)

INSTRUMENTS & CONTROLLERS (28)

The Influence of the Emission Property on the Determination of the Temperature of Liquid Iron. (Einfluss des Emissionsvermögens auf die Temperaturmessung am flüssigen Eisen.) RUDOLF HASE. *Archiv für Eisenhüttenwesen*, Vol. 5, Nov. 1930, pages 261–264; *Stahl und Eisen*, Vol. 50, Dec. 25, 1930, pages 1813–1814.

The paper summarizes the results of comparative temperature measurements taken on liquid cupola Fe with a thermocouple and an optical pyrometer (system Optix), respectively. In addition to these temperature measurements, moving pictures were taken of the sighted surface of the liquid metal. In comparing the true temperatures (thermocouple) with the relative temperatures (optical pyrometer), it is shown that the readings with the optical pyrometer should not be taken in the middle part of the spout of the cupola. The true and relative temperatures were found to be in satisfactory accordance only when the readings are taken when the jet of metal pours into the ladle. In 20 additional laboratory tests, the emission value of oxidized and non-oxidized metal surfaces was determined. In the temperature range from 1250° to 1600° C., the error of temperature of the non-oxidized metal surface continuously increases from 85° to 140° C. The similar curve of the temperature of the oxidized surface has a constant course up to 1400° C. but splits into 2 branches at this temperature. Between 1250° and 1600° C., the emission value of the non-oxidized Fe is on the average 0.44 ± 0.03; of the oxidized Fe, 0.95 ± 0.05. The paper, furthermore, contains temperature correction data of liquid Fe of various compositions. GN(28)

EFFECT OF TEMPERATURE ON METALS & ALLOYS (29)

Materials at High Temperatures. (Materialen bei hohen Temperaturen.) A. POMP (Kaiser Wilhelm Institut für Eisenforschung). *First Communications of the New International Association for the Testing of Materials*, Group A, Zurich, 1930, pages 80–84. 25 references.

Brief discussion of methods of testing. Alleges that limiting creep stress can be approximated in short-cut tests of the creep rate in the third and sixth hours if the test does not exceed 0.001%. A list of limiting creep stresses is given for 10 plain carbon steels of 0.06–0.29% C and for 4 nickel steels of 0.09–0.12% C with 3.18–4.80% Ni at 300°, 400° and 500° C. Figures given for steel of practically the same composition vary considerably. The figures on 2 steels of 0.06% and 0.07% C. at 400° C. are given as 10,000 and 14,000 lbs./in.², determined by the short-cut method. HWG(29)

LEACHING (30)

Chemistry of Leaching Covellite. JOHN D. SULLIVAN. *United States Bureau of Mines, Technical Paper* No. 487, 1930, 18 pages.

Covellite can be leached with ferric sulphate. The rate of dissolution was virtually the same for — 100 + 200 mesh covellite in solutions containing 1 and 2% of ferric iron; also for — 10 + 28 mesh material in 0.5 to 2% ferric iron solution. The rate was practically independent of acid strength for the first 8 days, when ferric iron concentration remained constant at 1%. Sulphuric acid in the presence of air attacked covellite at ½ the rate of ferric sulphate. Increased temperature markedly increased dissolution rate. Artificial covellite produced by leaching chalcocite dissolved at a much faster rate than natural covellite. AHE(30)

Agglomeration and Leaching of Slimes and Other Finely Divided Ores. JOHN D. SULLIVAN & ALFRED P. TOWNE. *United States Bureau of Mines, Bulletin* 329, 1930, 60 pages.

Cu in concentrator tailings can be recovered by agglomerating the ore and leaching by the open-drainage trickle method. Coarse material must be added to the sand and slime to act as a nucleus upon which the fine material can build. About 10% moisture is necessary. Solutions percolated freely through agglomerated ore containing up to 30% —200 mesh material with 90% extraction of acid solution Cu and 80% of total Cu when the ratio of oxidized to sulphide copper was approximately 1:1. By recirculation, Cu concentration was built up to 61 g./l. Experiments were conducted on all scales up to 12 tons. AHE(30)

REDUCTION METALLURGY (31)

Some Principles of Hot Blast Stove Design. A. J. BOYNTON & S. P. KINNEY (H. A. Brassert & Co.). *Blast Furnace & Steel Plant*, Vol. 18, Feb. 1930, pages 283–288.

Greatest efficiency is obtained where high gas velocities and turbulence of flow promote transfer by convection. Former is attained through use of small checker opening, the latter by disturbing stream line flow. Construction based on theoretical principles would be impractical from the operating point of view, because of lack of strength, inaccessibility to inspection, excessive pressure drop through the system, and the requirement of gas cleaned to engine specifications. Practical requirements of design which provides for thermal efficiency as well as for strength and convenience are: provision of maximum volume of brick within a minimum space, with the brick so arranged as to present the largest possible heating surface and to maintain high and substantially equal velocities of gases throughout all parts of the stove; small cross-section of flues, particularly in the cooler parts of the stove; continuity of checker flues, for convenience in inspection and repair; provision for creating turbulence of gases without excessive pressure drop through the stove; and adequate structural strength. Compares features of the Pfoser-Strack-Stum, Kuehn, and Brassert constructions. The larger the units and the less their number the more effective will be a given amount of heating surface, other things being equal. Theory and experience show that the use of more than two stoves with a single furnace is attended with considerable heat losses as well as unnecessary expenditure for equipment. MS(31)

Making Cobalt in an Electric Furnace. (La fabrication du cobalt au four electrique.) *Journal du Four electrique*, Vol. 39, Aug. 1930, page 288.

Three electric furnaces at Panda (Belgian Congo) melt either ore concentrates containing Fe, Cu and Co or Co rich slag of Cu smelting water jackets. Practically complete recovery of Cu and Co is obtained. The alloy is shipped to Oolen (Belgium) and is separated there. 708 tons Co were produced in 1929. JDG(31)

Interaction of Gases and Ore in the Blast Furnace. WILLIAM A. BONE, L. REEVE & H. L. SAUNDERS. *Fuels & Furnaces*, Vol. 8, Aug. 1930, pages 1089–1090.

From paper read before the Iron & Steel Institute. See *Metals & Alloys*, Vol. 1, Aug. 1930, page 686. MS(31)

Basic Open-Hearth Slag as a Valuable Blast Furnace Material. J. F. HORAK (Lukens Steel Co.). *Iron Age*, Vol. 126, Oct. 9, 1930, pages 980–981, 1046.

Open-hearth slag is suitable for blast furnace use because of its chemical composition as well as physical properties. Its chemical composition varies broadly, due to composition of pig Fe, scrap used, grade of steel made, etc. Mn recovery from the slag varies from 45% to 75%. Basic open-hearth slag contains about 20% silica, 42% lime, 7½% magnesia and same amount of Mn, 13% Fe and 3% Al_2O_3, for each 100 lbs. of slag. Sequences of good and bad melts indicate relation of pig Fe quality to steel making process. Mn content is important. On account of its P content, amount of basic open-hearth slag which can be charged into blast furnace is limited. Slag resulting from making low C steels are most suitable. VSP(31)

Blast Furnace Charging Installations and Their Influence on Operation. (Les Installations de Chargement de hauts fourneaux et leur influence sur la condutite de la marche.) HUBERT HOFF. Translated by A. Husson. *Revue de Metallurgie*, Vol. 27, Nov. 1930, pages 604–614.

A brief description and analysis of performance of different types of blast furnace charging devices used both in Europe and America. JDG(31)

Contributions to the Chemistry of the Chlorinating Roasting of Copper and Silver Ores. (Beiträge zur Chemie der Chlorierenden Röstung von Kupfer- und Silbererzen.) F. R. HIEMANN. *Metall und Erz*, Vol. 27, Sept. 1930, pages 474–486.

Contains 49 references. A detailed study is described of the individual chemical and thermal reactions taking place including the decomposition of chlorides by oxygen and steam alone, by oxygen and steam in the presence of acid anhydrides, the formation of chlorides by the action of Cl, and by the action of HCl, reactions between salts containing O and chlorides, between chlorides and sulphides or oxides. The effect of composition of the charge, furnace atmosphere, temperature and catalysts on the process of the chlorination of Cu and Ag ores is studied and discussed. CEM(31)

Investigations on the Friability of Coke Products. (Untersuchungen über die Zerreiblichkeit von Verkokungserzeugnissen.) F. HEINRICH & G. SPECKHARDT. *Stahl und Eisen*, Vol. 50, Dec. 11, 1930, pages 1750–1751.

The authors briefly abstract their article on the same subject in *Glückauf*, Vol. 66, 1930, pages 1285–1292. The various methods of determining the friability of coke which have been used and suggested up to the present time have been critically examined. Conclusions are drawn as to the further development of the practice of testing coke. GN(31)

Blast Furnace Construction and Operation. WILLIAM A. HAVEN (Arthur G. McKee & Co.). *Blast Furnace & Steel Plant*, Vol. 16, Jan. 1930, pages 85–89.

Reviews developments during 1929. Trend has been toward larger furnaces. Several with a 25 ft. or more hearth diameter have been constructed and have proved highly satisfactory. They may be depended upon to produce 1000 or more tons daily. Tendency in stove checker construction is toward smaller openings and thinner walls. Much attention has been given to better gas cleaning equipment. First American installation of disintegrator type washers was made during the year. A record production of 42,500,000 tons of pig-iron was accomplished by an average of only 205 furnaces in blast. The trend in operating practices has been toward greater output per stack, use of higher blast temperatures, reduction of dust losses, and more profitable use of blast-furnace gas. MS(31)

Improvement of Existing Blast Furnaces. JAMES P. DOVEL. *Blast Furnace & Steel Plant*, Vol. 18, Aug. 1930, pages 1285–1286, 1296.

Furnace, an illustration of which is shown, has been redesigned with a thinner inwall lining and with inwall cooling plates and metal top. The shell is strengthened by means of H-beams equally spaced around it, supported by the mantle or by suitable brackets on the lower ring and extending to the furnace-top platform. The advantages claimed are increase in volume above the bosh of 27.4%; increase in stock-line with resultant decrease in quantity of flue-dust; a bell ratio to stock-line which will make active the total area of the furnace; greatly increased contact of gases and stock, with increased thermal efficiency, coke/ton of Fe having been decreased 16–22%; and permanent inwall lining with the relining charge eliminated for this section of the furnace. MS(31)

Furnace Operations in the South. JAMES P. DOVEL (Sloss-Sheffield Steel & Iron Co.). *Blast Furnace & Steel Plant*, Vol. 18, Jan. 1930, page 113.

Outstanding features in blast-furnace practice are the increasing of stock line diameter and inwall cooling. Tonnage has improved in almost direct proportion to the increased volume of stock column, coke consumption/ton of Fe has been reduced, and flue-dust has been decreased. MS(31)

Effect of High-Grade Concentrates in Reverberatory Practice at Anaconda. JAMES J. DOUGHERTY. *Mining & Metallurgy*, Vol. 11, Aug. 1930, pages 389–391.

Presented before the Montana section April 7, 1930. A general discussion of developments in reverberatory smelting practice by the Anaconda Copper Mining Co., during the last 5 years. Deals briefly with changes in furnace types, in furnace feed, decrease in amount of slag produced, relation of slag assays to Cu loss in the slag, increase in grade of matte and furnace capacities. Gives a brief summary of topics discussed and conclusions derived therefrom. VSP(31)

Concentrate Hematites to Replace High-Order Ores. E. W. DAVIS (Mines Experiment Station, Univ. of Minn.). *Iron Age*, Vol. 126, Oct. 30, 1930, pages 1219–1220.

Abstract of paper presented at the Chicago meeting of the American Institute of Mining and Metallurgical Engineers, Sept. 1930. VSP(31)

Modern Methods of Ore Concentration. (Les methodes modernes de concentration des minerais.) CH. BERTHELOT. *Revue de Metallurgie*, Vol. 27, Oct. 1930, pages 535–543.

General principles of mineral concentration are given together with the description of principal methods including flotation. The installation for handling flotation wastes at Inspiration is described. The flow sheet and some details are given about the plant at Orb (Herault) using differential flotation and handling blende-pyrites-galena ores. JDG(31)

Ore Size and Blast-Furnace Economy. S. P. KINNEY. *Blast Furnace & Steel Plant*, Vol. 18, March 1930, pages 472–475.

Reprinted from *United States Bureau of Mines Reports of Investigations*, Nos. 2982 and 2983. See *Metals & Alloys*, Vol. 1, Oct. 1930, page 790. MS(31)

The Properties of Coke. *Iron & Coal Trades Review*, Vol. 121, Aug. 22, 1930, pages 253–254.

Abstract of a paper on "The Impact Hardness, Abrasion Hardness and Reactivity of Coke" read by R. A. Mott before the Midland Section of the Coke Oven Managers' Association. Discusses the "shatter" test, forces acting on coke in the blast furnace, nature of the coke and forces acting at the tuyères, drum-abrasive tests, and the reactivity of coke. Blast furnace coke should not be abradable. Hardness should be high. Hard coal is less liable to form breeze. Marked reactivity is not generally desirable in blast furnace coke. RHP(31)

Blast Furnace Versus Reverberatory. W. C. Davis. *Canadian Mining Journal*, Vol. 51, May 2, 1930, pages 410–413; *Metal Industry*, London, Vol. 37, July 11, 1930, page 1930.

A discussion of the relative merits of 3 current smelting methods and a suggestion as to future practice. Reflections center on the erection of a concentrator and reverberatory furnace plant at Copper Cliff for the International Nickel Company. Advantages and disadvantages of blast furnace and reverberatory furnace and the advances in reverberatory practice are pointed out. Also the value of sintering and the effect flotation may have in the induction of new smelting methods. VSP+WHB(31)

The Influence of Moisture Due to Leaking Tuyères on Blast Furnace Conduct. C. D. Abell. *Foundry Trade Journal*, Vol. 43, Oct. 9, 1930, page 247.

The moisture in the blast varies. The "winter" average is about 0.40 lbs./ft.^{3} and the "summer" about 0.60 lbs./ft.^{3} It is the only source of moisture which continually dilutes the reactions of the blast furnace. Moisture causes the formation of the Fe and Mn spinel oxides instead of the normal spinels (hercynite). Specific figures indicate losses of Fe, due to excessive moisture, presuming that equilibrium is obtained. Since this never proves practical, the figures simply indicate how disastrous the reactions can become, since it tends to give fusible scouring silicates, with the consequent occurrence in the hearth of pieces of apparently unreduced ore, consisting mainly of magnetic oxide of iron; and also accounts for the "slushy" or pasty character of the Fe cast when the furnace is running irregularly due to the presence of magnetic oxide (Fe_3O_4) in the iron. The direct results of excessive moisture is a regular working, low-temperature iron, with excess of sulphur and oxide, combined with poor fuel economy and an increase in the rate of furnace driving with lessened production. A factor of prime importance in this respect is the greater rate of combustion of hydrogen from the hydrogen-carbon monoxide mixture of the upper zones with attendant disorganization of the carbon monoxide dissociation reaction upon which the furnace depends for regularly economic working. The extent of the possible reactions is a function of the rate of driving, and the only remedy is to introduce more fuel and extra blast, if danger is suspected from a leaking member (0.50 lbs. water/100 ft.^{3} of blast is believed beneficial in most cases, by producing a certain amount of oxide in the iron. Above this figure it becomes a source of trouble.) WHB(31)

Concentration of Swedish Iron Ores. (Hüganrikning av svenska järnmalmer.) Gust. G. Bring. *Jernkontorets Annaler*, Vol. 114, Oct. 1930, pages 64–132, 12 references.

The concentration referred to is concentration to produce as nearly pure Fe mineral as possible. Magnetite ore can be concentrated successfully by magnetic separators and concentration tables. Hematite can be concentrated by concentration tables, by flotation, or by magnetic roasting. The concentration table causes too great losses. Flotation appears to require extremely fine grinding which adds too much to the expense. Roasting to convert Fe_2O_3 to magnetic Fe_3O_4 was finally resorted to, the reducing agent being air dried saw dust. It was found that the transformation took place with measurable speed at 400° C. but the speed increased up to 800° C. Cooling of the roast should take place as rapidly as possible for hematite and might advantageously be done in water since wet grinding is required. Limonites, however, should be cooled slowly in air from 400°–500° C. Microphotographs indicate that the magnetized roast is a mixture of Fe_3O_4 and FeO rather than a solution. Large scale tests using producer gas as fuel showed that a concentrate of over 69% Fe could be obtained. The heat requirements were found to be 10.4% by weight of wood for a 40% ore of which 30% is present as Fe_2O_3. For charcoal 4.8% by weight is needed. The product is in a very friable condition and easily crushed. Industrial installations have produced a concentrate with 68.32% Fe, and a 92.7%, recovery. HCD(31)

The Technical Conditions of Zinc Smelting by the Continuous Process. (Die technischen Bedingungen der Zinkverhüttung in kontinuierlich arbeitenden Systemen.) Herbert Cohn. *Metall und Erz*, Vol. 27, July 1930, pages 357–362.

Discusses the operation of vertical muffle furnaces, gas tightness of assembled muffle-columns, construction of charging and tapping openings, effect of slag, change in temperature and metal vapors on the lining. Describes the process of zinc smelting at Oberspree, of the New Jersey Zinc Co., and the Coley process. CEM(31)

Chain Filter Installed at Stock Line Curtails Dust Loss. Julius Stoecker. *Iron Trade Review*, Vol. 86, Feb. 6, 1930, pages 79–80.

Abstract from *Stahl und Eisen*, Sept. 5, 1929. MS(31)

Air Discharge of Circular Tuyères. Richard S. McCaffery & Daniel E. Krause (University of Wisconsin). *American Institute of Mining & Metallurgical Engineers, Technical Publication* No. 385, 1931, 10 pages.

The adoption of divergent blast-furnace tuyères by a German plant has been reported to result in a decrease in blast pressure and increased output. Tuyères of different design were tested by casting samples 1/5 of the usual size and determining rate of air flow and air pressure at different points in front of the tuyères. Both the length and divergence of the tuyères affect the spreading of the emergent air. It is concluded that the benefits derived from the use of divergent tuyères are due to a better distribution of the air rather than to the immediate shape of the air stream. Contains 1 reference. JLG(31)

A Statistical Analysis of Blast-Furnace Data. Richard S. McCaffery & Roland G. Stephenson (University of Wisconsin). *American Institute of Mining & Metallurgical Engineers, Technical Publication* No. 384, 1931, 13 pages.

Daily reports were obtained from 15 blast-furnaces. The data, including mineral composition of the slag, output, analysis of the iron, fuel consumption and moisture content of the air, were listed and classified by a tabulating machine. Slag compositions were expressed in mineral composition. In order to find the effect of one factor on another the cards were sorted into groups in which all other factors in each group were within rather narrow limits. The necessary data were then plotted. Increased Si in the iron is accompanied by a slight decrease in tonnage. The coke consumption per ton of iron is increased 100 lbs. for each 1% increase in Si. S elimination varies directly with Si in iron. The ratio of S in slag to S in metal increases with Si content of metal. Increased calcium bisilicate is accompanied by a decrease in S ratio. Contains 6 references. JLG(31)

Effect of Magnesia on Slag Viscosity. Richard S. McCaffery, Joseph F. Oesterle & Oscar O. Fritsche. *American Institute of Mining & Metallurgical Engineers, Technical Publication* No. 383, 1931, Third paper, pages 55–68.

Data for this report was taken from the second paper in this technical publication. The viscosity of slags of definite composition and at definite temperatures are plotted on plane triaxial diagrams showing compositions of silica, lime and alumina on planes representing constant magnesia contents. Only part of the data are included in the report. Temperatures of 1400°, 1500° and 1600° C. and planes of constant magnesia content of 0, 5, 10, 15 and 20% were selected. The most striking fact observable from the vicosity diagrams is that with a higher magnesia content there is less change in viscosity when silica, alumina, and lime vary among themselves than there is with a lower magnesia content. A means for detailed study of the diagram is outlined. Sections along various alumina-silica ratio lines at 1400°, 1500° and 1600° show that the general effect of magnesia is to flatten the curves. In the same manner the effect of alumina and lime were illustrated. CHL(31)

Determination of Viscosity of Iron Blast-Furnace Slags. Richard S. McCaffery, Clarence H. Lorig, Ira N. Goff, Joseph F. Oesterle & Oscar O. Fritsche. *American Institute Mining & Metallurgical Engineers, Technical Publication* No. 383, 1931, Second paper, pages 27–54.

A report of an investigation to determine the relations between the viscosity, temperature and composition of that portion of the silica–alumina–lime–magnesia system within which blast-furnace slags are found. Except for the substitution of a square bob for the usual cylindrical spindle, the apparatus for measuring viscosities was of the Margules rotating cylinder type. The apparatus and its operation are described. Greater accuracy with the use of the square bob was reported. Synthetic slags with composition corresponding to various mineral compounds were made from the pure oxides lime, magnesia, alumina and silica. The minerals and mineral combinations were used in forming binary, ternary and quaternary mixtures of slag minerals. A complete table of the mineral composition, chemical composition and viscosity in poises at 1650°, 1600°, 1550°, 1500°, 1450°, 1400°, 1350°, 1300° and 1250° C. for 168 slags is given. A comparison of viscosities of slags in the ternary system silica–alumina–lime to those of Feild and Royster reported in their Slag Viscosity Tables show little in common. Various possible causes suggested to account for the discrepancies in the results of the 2 investigations are based on differences in technique and operation of the apparatus. The authors believe that improved design and manipulation incorporated in their apparatus lend themselves to greater accuracy in measuring the viscosity of molten slags. 26 references are cited. CHL(31)

Research on Blast-furnace Slags. A Progress Report. Richard S. McCaffery. *American Institute of Mining & Metallurgical Engineers, Technical Publication* No. 383, 1931, pages 5–26.

Observations, tests and data obtained through research on iron blast-furnace slags now in progress at the Metallurgical Department of the University of Wisconsin are commented upon. The comments apply more specifically to viscosity determinations made on samples of synthetically prepared slags in the composition range: silica 25 to 55%; alumina 0 to 35%; lime 25 to 55%; magnesia 0 to 20%. The most noticeable thing observed was the effect of the magnesia in reducing the viscosity of slags. The possibility of greater regularity of furnace operation through use of high magnesia slags is brought out. Thirteen diagrams showing the effect of magnesia and alumina on the viscosity of slags with various constants are given. In this report the viscosity determinations on blast furnace slags are summarized in 3 series of diagrams. Temperatures of 1400°, 1500° and 1600°C. were selected. One series gives the viscosity in terms of the alumina-lime-magnesia compositions with silica varying 5%. Another series gives the viscosity of silica-alumina-magnesia compositions with lime varying 5% and a third series gives the viscosity of lime-magnesia-silica compositions with alumina varying 5%. The report contains a total of 79 diagrams. CHL(31)

Alkaline Cyanides in the Blast Furnace. W. McConnachie (Coltness Iron Works). *Blast Furnace & Steel Plant*, Vol. 18, Sept. 1930, pages 1449–1450, 1454.

Same article that was published in *Chemical Age*, Vol. 22, April 5, 1930, Monthly Metallurgical Section, pages 21–22. MS(31)

Study of Iron Ore Sinter. G. M. Schwartz (University of Minnesota). *Blast Furnace & Steel Plant*, Vol. 18, March 1930, pages 462–467, 471.

Iron-Ore Reduction in the Hot-Blast Furnace. Wm. McConnachie. *Iron & Coal Trades Review*, Vol. 121, Aug. 29, 1930, page 289.

Describes experimental work done by Bell to determine the effect of gases produced by the combustion of coke, or fixed C in the removal of O from the ore. Tests were made with a Clarence furnace using coke and a Lanarkshire furnace using coal. No O is removed from the ore by H in ordinary practice. Carbon monoxide also fails to remove an appreciable amount of O. Several theories have been advanced as to the removal of the O but none of them have been fully proven. The author suggests further research in the field using the small size coal burning furnace. RHP(31)

Use of Thermodynamical Data to Study the Chemical Reactions of Metallurgical Processes. R. S. Dean. *United States Bureau of Mines, Information Circular* 6395, 1930, 12 pages.

Examples are given to show how by the application of thermodynamic results new methods are proposed for deoxidation of copper, production of zinc and separation of zinc and cadmium. AHE(31)

NON-METALLIC COATINGS FOR METALS (32)

Effect of Furnace Gases on Quality of Enamels. A. I. Andrews & E. A. Hertzel. *Fuels & Furnaces*, Vol. 8, April 1930, page 511.

Abstract of paper read before the American Ceramic Society, Feb. 16–21, 1930. Investigation showed SO_2 in furnace gases is detrimental to enamels burned therein. Small white pock marks which could not be washed off with water were formed on sheet steel ground coats. White sheet steel cover coats were attacked in the same way, but the marks were more difficult to distinguish. Variations in composition of the ground coats produced little variation in the resistance to attack. Variations in the composition of cover coats in certain cases produced large variations in the resistance to attack. MS(32)

Effect of Furnace Gases Upon Vitreous Enamels. E. E. Geisinger & K. Berlinghof. *Fuels & Furnaces*, Vol. 8, March 1930, pages 357–358.

Abstract of paper read before American Ceramic Society, Feb. 16–21, 1930. Investigation of the effect of 100% concentrations of stable elementary gases and some mixed gases on ordinary steel enamels. O_2 gave enamels with excellent qualities, but the steel was excessively oxidized. The gases which were deleterious to enamels were: H, H_2O vapor, Cl, H_2S, NH_3, oil gas and SO_2, their harmfulness decreasing in the order given. MS(32)

Use of Conveyors in Japanning Ovens. W. J. Miskella. *Fuels & Furnaces*, Vol. 8, Aug. 1930, pages 1077–1078, 1084.

Discusses construction and operating features of conveyor type japanning ovens. MS(32)

Finishing Automobile Tire Rims. E. H. Ledyard (Consumers Power Co.). *Metal Cleaning & Finishing*, Vol. 2, May 1930, pages 427–428.

In the plant of the Motor Wheel Corp., Lansing, Mich., rims are pickled in 5% H_2SO_4 bath, rinsed, rust-proofed by galvanizing and treating with antimony oxide, rinsed, and dipped in enamel, which is baked in a continuous conveyor at 375°–400° F. MS(32)

MANUFACTURERS' LITERATURE REVIEWS

In this department we each month list the catalogs and other printed matter issued by manufacturers. Unless otherwise noted, any of the items listed may be secured free upon application to the issuing firm. Manufacturers who have not yet sent in their printed matter are invited to do so.

401 **Costello Burner.**—A very complete description of their raw producer gas burner is given in a folder sent out recently by the Costello Engineering Co., 519 Oliver Bldg., Pittsburgh, Pa.

402 **Rolled Steel.**—Lukenweld Construction is the fabricated product obtained by welding Lukens rolled steel and is an efficient and economical method of manufacturing units such as housing, bases, beds, gear cases and other parts of machinery and equipment. This construction is fully discussed in a booklet prepared by Lukenweld, Inc., Coatesville, Pa.

403 **Steel Castings.**—The Industrial Steel Casting Company, Toledo, Ohio, has issued a series of folders illustrating the kind of machining job that can be done on their castings, and giving a number of views of their plant.

404 **Timbre.**—Technical Bulletin "C", prepared by the research department of the Carpenter Steel Co., Reading, Pa., is a 20-page report which defines "timbre" and tells how it affects the properties of carbon tool steel. The report contains a number of illustrations.

405 **Alloy Steel Valves.**—This new line of valves, manufactured by the Duriron Company, Inc., Dayton, Ohio, is especially applicable for those conditions of hard mechanical service where high pressures and high temperatures are encountered in transferring corrosive liquids and gases through pipe lines. They are described in a folder issued by the company. Their Bulletin 164 is devoted to Duriron Centrifugal Pumps.

406 **Ajax Seven Point Ingot.**—The Ajax Metal Company, Frankford Ave. & Richmond St., Philadelphia, Pa., has recently sent out to the trade a booklet giving detailed information on their non-ferrous ingots, both standard and special and includes a table giving the A. S. T. M. tentative specifications for standard alloys.

407 **Molybdenum.**—An attractive brochure gotten out by the Climax Molybdenum Co., 295 Madison Ave., New York, discusses thoroughly the effect of molybdenum on cast iron. It contains numerous tables and figures. This company has also published a book, "Molybdenum in 1930," presenting facts about the various uses and applications in industry of molybdenum. These technical data are from authoritative sources and free from advertising bias.

408 **All Metal House.**—The feature article of the Jan. 15, 1931 issue of the bulletin of the Copper & Brass Research Association, 25 Broadway, New York, concerns an all-metal, factory-made house being introduced in Germany. The whole issue is devoted to articles on recent developments in Germany in the employment of copper and its alloys in building construction.

409 **Annealing Furnaces.**—A broadside sent out by the Surface Combustion Corp., Toledo, Ohio, illustrates several of their annealing furnaces which have been developed to meet specific operating conditions.

410 **Wrought Iron.**—A quantity of interesting information concerning wrought iron has been collected by the Wrought Iron Research Association, Union Bank Building, Pittsburgh, Pa., and has been published in booklet form. It includes both technical and non-technical data.

411 **The Octagon.**—The feature article in the Jan. 1931 issue of this publication of the American Steel Foundries, Wrigley Bldg., Chicago, is "The Growth of the Locomotive" by W. G. Greene. Mr. Greene also has an article in the February issue entitled "Railroad Development in Spain."

412 **"Neor."**—This non-deforming high carbon-chrome steel is a product of Darwin & Milner, Inc., 1260 West 4th St., Cleveland, Ohio, and is described in a recent pamphlet, which includes general heat treatment instructions for this steel.

413 **Ingot Bronze.**—A brief covering physical properties and various data in connection with valve and metal ingots produced by the Tottenville Copper Co., Inc., Tottenville, N. Y., is available. This gives facts about ingot bronze for valves, meters, high-grade machinery castings or any work requiring a close-grain, easily machined metal.

414 **Carboloy.**—The Jan. 1931 issue of this publication contains a number of interesting articles, among them being "Application of Carboloy Tools to Facing Zinc Die Castings," "Reaming a Tapered Hole in Alloy Brass," and Rockwell-to-Brinell conversion tables. Carboloy Company, Inc., Detroit, Michigan.

415 **Diffraction X-Ray Apparatus.**—Bulletin No. 12, issued by the J. B. Hayes Machine Company, Urbana, Illinois, lists X-Ray apparatus manufactured by the company, including tubes, cameras and several types of cassettes.

416 **Hydro-Power.**—A broadside sent out by the Hydraulic Press Mfg. Co., Mount Gilead, Ohio, lists the standard sizes and capacities of their hydro-power presses.

417 **Lead.**—The March 1931 issue of this publication of the Lead Industries Association, 420 Lexington Ave., New York, tells about a number of interesting uses of lead among them being the use of lead pads to dampen machinery vibrations in a newspaper plant.

418 **Sandslingers.**—The Feb. 1931 issue of "Better Methods" is devoted to a discussion of this type of apparatus manufactured by the Beardsley & Piper Co., 2541 North Keeler Ave., Chicago, Ill.

419 **Electrodes.**—A folder issued by the International Graphite & Electrode Corp., Niagara Falls, N. Y., stresses the facilities, organization and policy of the company and announces the opening of their new plant.

420 **Fusion Facts.**—The leading article in the Jan. 1931 issue of this periodical is "Borium—Its Properties and Its Uses" by Miles C. Smith. Several interesting applications of Stoody products are discussed in other articles.

421 **Electric Heating Furnaces.**—Bulletin No. 5 of Ryan, Scully & Co., Philadelphia, Pa., describes and illustrates their portable box-type electric heating furnaces. These furnaces are the result of many years' research and practical experience. Bulletin No. 7, by the same company, discusses their butterfly type blast gates.

422 **Engineering Metals for the Process Industries.**—A pamphlet with this title has been gotten out by the International Nickel Co., 67 Wall Street, New York, and contains an article on the design and construction of heavy equipment in monel and pure nickel and reprints a number of advertisements of firms who use these metals in their products.

423 **Interferometers.**—Catalog No. 1, of the Gaertner Scientific Corporation, 1201 Wrightwood Ave., Chicago, Ill., lists and describes the different forms of interference apparatus manufactured by the company.

424 **Dust-Collectors.**—A particular installation of one of their dust-collecting systems is discussed in Bulletin No. 20 of the Dust Recovering & Conveying Co., Harvard Ave. & East 116th St., Cleveland, Ohio.

425 **Manganese Steel.**—The Feb. 1931 issue of the Amsco Bulletin shows the use of manganese steel for dredge buckets all over the world. A number of other products of the American Manganese Steel Company, Chicago Heights, Illinois, are illustrated.

426 **Struthers-Weld.**—A page of micro-photographs showing the juncture between the parent metal and the weld metal has been prepared by the Struthers-Wells Co., Warren, Pa.

427 **Corrosion.**—An interesting article on the "Corrosion of Rivets in Marine Vessels" is featured in the Vol. 1, No. 4 issue of The Wrought Iron Record which is published by the Wrought Iron Research Association, Union Bank Building, Pittsburgh, Pa.

428 **Metallographic Polishing Machine.**—A folder sent out recently by the American Instrument Company, 774 Girard Street, N. W., Washington, D. C., gives an excellent description of their Automatic Metallographic Polishing Machine.

429 **Cadalyte.**—This booklet by the Grasselli Chemical Co., Cleveland, Ohio, gives the development of Cadalyte, a process and product for cadmium plating, and discusses the operation of the process in the plating room.

430 **Metal Spraying Process.**—This booklet by the Metal Spray Engineering Co., 3501 Croton Ave., Cleveland, Ohio, explains their method of spraying metals, gives a list of metals that can be successfully treated this way and suggests a number of objects which can be advantageously lined or coated by spraying.

431 **Gray Iron.**—Bulletin No. 1 of the Gray Iron Institute, Inc., Terminal Tower Bldg., Cleveland, Ohio, discusses the dome of the Capitol building which is made of gray iron. Bulletin No. 2 is a short essay on the gray iron work in the Holland Tunnel.

432 **Furnaces.**—Homo furnaces are successfully used for normalizing and heat treating bolts because they hit the predetermined correct temperature precisely and unfailingly. They are illustrated in a folder prepared by Leeds & Northrup Company, 4901 Stenton Ave., Philadelphia, Pa. This folder also has a word about Hump hardening for drop-forge dies.

433 **The Laboratory.**—Among other interesting items, the Vol. 4, No. 1 issue of this periodical contains two pages of the temperature conversion tables compiled by Sauveur. The publishers are The Fisher Scientific Company, 711 Forbes St., Pittsburgh, Pa.

434 **Zinc.**—Two recent publications of the American Zinc Institute, 27 Cedar St., New York, N. Y., are Zinc and Its Corrosion Resistance, and Zinc Workers' Manual. The first of these presents in abstract form existing data concerning studies, investigations, tests, equipment and researches in this practical field of the use of zinc and is priced at $1.00. The Manual is devoted to the methods and practice of zinc roofing and may be had for $1.50.

435 **The Steel Founder.**—The March 1931 issue of this publication reprints an address by W. Trinks before the Steel Founders' Society at Columbus, March 19th, in which he discusses the "Selection of Materials in Machine Design." This is published by the Society, 932 Graybar Bldg., New York, N. Y.

436 **Meeting the Metal Requirements of Boatbuilding.**—A booklet with this title gotten out by the International Nickel Company, 67 Wall St., New York, is a very interesting discussion of the use of Monel metal in boatbuilding. Its resistance to corrosion in both salt and fresh water especially fits it for such use. Another of their pamphlets, "Modern Ideas in Food Plant Sanitation," illustrates the numerous uses to which Monel metal can be put in the canning factory.

437 **Fifty Years of Service to Industry.**—An extremely attractive brochure sent out by the Pittsburgh Testing Laboratory, Pittsburgh, Pa., describes the facilities and service of this institution with regard to physical testing, chemical analyses, engineering inspections and research.

438 **Better Heat.**—In the February issue of this publication of the Consolidated Gas Company of New York, 4 Irving Place, New York, there is a short summary of E. D. Milener's studies in the application of gas heat to forging and other uses as brought out in his address before the Rhode Island Chapter of the A.S.S.T.

CURRENT METALLURGICAL LITERATURE ABSTRACTS OF METALS & ALLOYS

PUBLISHED MONTHLY BY THE CHEMICAL CATALOG COMPANY, INC.

419 Fourth Ave., New York

Editorial and Advertising Offices: 3619 Forbes Street, Pittsburgh, Pa.

Annual Subscriptions: U. S., Possessions, Mexico and Cuba, $3.00; Canada, $3.50; Other Countries, $4.00; Single copies, 40¢.
Copyright, 1931, by The Chemical Catalog Company, Inc. All rights reserved.

Note. The September issue of METALS & ALLOYS will be Vol. 2, No. 3. For purposes of binding and filing, these monthly bulletins may be considered as Vol. 2, No. 2a, 2b, etc

These abstracts are not critical, but merely review developments. The classification number at the end of each abstract will be of assistance in mounting them on filing cards.

Negative print photostats of the original articles abstracted below can be obtained at 35 cents per page, plus 10 cents for mailing first class. The remittance should accompany the order.

Book Reviews are included below and marked by -B-

CONTENTS—MAY 1931

PATENT SERVICE

Until we resume regular publication in September, the service rendered by the Patent Department of METALS & ALLOYS will be carried on by Mr. W. M. Corse, 810 Eighteenth Street, Washington, D. C. who can supply copies of United States and foreign patents and translations at reasonable costs.

GENERAL (0)

Tool Steel Progress in the Twentieth Century. JOHN A. MATHEWS (Crucible Steel Co. of America). *Iron Age*, Vol. 126, Dec. 4, 1930, pages 1672–1676.

Abstract of paper read before the New York chapter of the American Society for Steel Treating, Oct. 13 and the Syracuse chapter, Dec. 3. The twentieth century may fittingly be called the "Alloy Age." High-speed steel was introduced in 1900. High-speed steel and the electric furnace are the outstanding events responsible for the progress of the last 30 years. C-V tool steels, Cr-V, Ni-V and Ni-Cr-V structural alloys and V-high-speed steel were produced about 1903. Carborundum production introduced by E. G. Acheson constitutes an early development of commercial electric furnace work. Electric furnace has functioned in 2 ways: (1) in direct melting process for the steel itself, and (2) in smelting process. First electric furnace installed by the Halcomb Steel Co., Syracuse in 1905. Demand for steels for dies and tools resulted in development of W hot die steels. No oil-hardening die steel available before 1905. Principal purpose of research in steel industry is to increase profits. VSP(0)

The "Launching" of Magnesium. (Le "demarrage" du magnesium.) C. D. *Journal du Four Electrique*, Vol. 39, Sept. 1930, pages 325–326.

General information regarding the introduction of Mg into metallurgical uses. JDG(0)

Physics as an Aid to Metallurgy. REPUBLIC RESEARCH CORPORATION. *Iron Age*, Vol. 126, Oct. 16, 1930, pages 1066–1067, 1117–1119.

There is no theoretical method by which it is possible to get the true properties of metals. Fundamental considerations of physics are valuable in suggesting further experimentation. An organization whose duty is to develop processes for production in a manufacturing organization must have a staff of physicists, physical chemists and metallurgists. One of the most interesting recent developments of physics, which is applicable in metallurgy, is X-ray diffraction work. VSP(0)

Report of American Society for Testing Materials Special Committee on Promotion of General Use of Specifications for Copper Alloys in Ingot Form. *Proceedings American Society for Testing Materials*, Vol. 30, Part 1, 1930, pages 412–414.

See *Metals & Alloys*, Vol. 1, Oct. 1930, page 791. (0)

Aeronautical Research. *Engineering*, Vol. 130, Oct. 17, 1930, pages 483–484.

Comments on Report of Aeronautical Research Committee for 1929–1930 recently published by His Majesty's Stationery office. Among problems discussed is that of increased use of metals in aircraft constructions. Corrosion of Al alloys and means for its prevention are important problems. Mg alloys and Be have been considered but as yet they are inferior to Al alloys. Al alloy castings has been greatly improved by grain refinement and gas removal from melts. For this, the use of titanium tetrachloride has been satisfactory. LFM(0)

Science and Electrical Engineering. E. W. MARCHANT. *Engineering*, Vol. 128, Oct. 25, 1929, pages 536–537.

Abstract of paper read before the Mersey and North Wales (Liverpool) Centre of the Institution of Electrical Engineers. Reviews advances made in electrical engineering due to contributions of pure science. Discovery of Si iron has caused progress to be made in transformer design and construction. Use of Co steel has led to revolution in design of permanent magnets. Great benefits have been derived from use of Ni-Cr alloys in electric heaters. Discovery of Permalloy has enabled speed of transmission in telephone and telegraph cables to be increased 4 to 5 times. LFM(0)

Science and the Iron and Steel Industry. ARTHUR D. LITTLE (Arthur D. Little, Inc.). *Blast Furnace & Steel Plant*, Vol. 18, July 1930, pages 1126–1129, 1134; *Heat Treating & Forging*, Vol. 16, June 1930, pages 738–742; Condensed in *Rolling Mill Journal*, Vol. 4, May 1930, pages 209–211.

Paper read before American Iron & Steel Institute, May 9, 1930. See *Metals & Alloys*, Vol. 1, Oct. 1930, page 791. MS(0)

Metallurgy Encounters New Problems. L. M. JORDAN. *Heat Treating & Forging*, Vol. 16, Jan. 1930, pages 75–76, 131.

Outlines some of the contributions of metallurgy to the development of materials for automotive and aircraft engines. Much remains to be done in improving the properties of metals so that failures will be rare. MS(0)

Bessemer Output Becomes More Important. JOSEPH R. MILLER. *Blast Furnace & Steel Plant*, Vol. 18, June 1930, pages 973–974.

Certain steel products are best made from Bessemer steel. Bars may be easily welded and be stronger and stiffer than equally good welding grades in open-hearth steel. Bessemer steel threads more easily and it has not been equaled as a free cutting steel. Attention is being paid to improvement of quality. Trend in vessel design is toward comparatively greater diameters with less depth of metal above the tuyères. In general, satisfactory Bessemer Fe will blow with about 18,000 cu. ft. of air/ton of metal. Blast pressures are about 25 lb./in.^{2} or 22 lb./in.^{2} Bessemer Fe should contain 0.80–1.40% Si (this being somewhat higher in summer than in winter), not more than 0.60% Mn, and under 0.090% P. MS(0)

Nickel and Its Alloys. A. J. WADHAMS. *Mining and Metallurgy*, Vol. 10, April 1929, pages 183–189.

A paper read before the Spring Meeting of the American Institute of Mining and Metallurgical Engineers gives a historical survey of the development of nickel and its alloys from earliest times to the present day, and contains brief notes on the results of early research and a review of post-war expansion in the nickel industry. The summary which is given of present-day applications of nickel and its alloys forms a striking statement on the wide range of industries in which nickel is playing an important part. Reference is made to the use of ferro-nickel alloys of high magnetic permeability, of non-magnetic alloys of iron and nickel in the electrical industry, of nickel in constructional steels, of heat- and corrosion-resisting alloys containing varying percentages of nickel, of "nickel silver" for cutlery and tableware, and of the numerous applications of nickel as a modifying element in a number of ferrous and non-ferrous materials. Reference is also made to the use of nickel as a catalyst in the preparation of edible oils, as an active material in storage batteries, in coinage, and in the form of electrodeposited coatings. The paper closes with some comments on recent developments in connection with the mining of nickel-copper ore at Sudbury, Ontario. (0)

Manufacture of Die Blocks. J. P. BINDYKE (Heppenstall Company). *Heat Treating & Forging*, Vol. 16, July 1930, pages 864–868, 880.

Description of the open-hearth, forging and heat treating practice of the Heppenstall Co. MS(0)

Current Vogues in Metals. HERBERT CHASE. *American Machinist*, Vol. 73, Sept. 18, 1930, pages 479–481.

Brief information concerning various metals now in use, mostly of the non-corrosive type. Gives type of metal, approximate percentage of the chief alloy and some uses. Material not original but gleaned from various sources. RHP(0)

Developments in Nickel Iron and Steel. CHARLES MCKNIGHT (International Nickel Co.). *Blast Furnace & Steel Plant*, Vol. 18, June 1930, pages 968–970; July 1930, pages 1149–1151. Condensed in *Iron Trade Review*, Vol. 86, May 29, 1930, pages 45–47, 61. Abstracted in *Rolling Mill Journal*, Vol. 4, May 1930, page 218; *Metal Stampings*, Vol. 3, June 1930, page 526.

Paper read before American Iron & Steel Institute, May 9, 1930. See *Metals & Alloys*, Vol. 1, Aug. 1930, page 687. MS(0)

Developments of the Past Year in Metal Finishing. WILLIAM J. MISKELLA (Finishing Research Laboratories, Inc.). *Metal Cleaning & Finishing*, Vol. 2, Jan. 1930, pages 59–62.

Deals with equipment and materials. MS(0)

Metallurgical and Chemical Progress in British Columbia During 1930. F. H. MASON. *Canadian Chemistry & Metallurgy*, Vol. 15, Jan. 1931, pages 30–31.

A review. WHB(0)

PROPERTIES OF METALS (1)

Recommended Specifications for Analytical Reagent Chemicals. Sodium Metal. COMMITTEE ON ANALYTICAL REAGENTS, AMERICAN CHEMICAL SOCIETY. *Industrial & Engineering Chemistry, Analytical Edition*, Vol. 2, July 15, 1930, pages 351–354.

The requirements of purity of sodium metal and the tests for determining these requirements are listed. Requirements for metal salts are also given in this article. MEH(1)

Copper—Cuprous Oxide Eutectic and Density of Copper. (Kupfer—Kupferoxydul und dichte des Kupfers.) W. STAHL. *Metall und Erz*, Vol. 27, Aug. 2, 1930, page 414.

The Cu-Cu_2O eutectic occurs at 96.5–96.6% Cu and 3.4–3.5% Cu_2O at 1065° C. Density determinations give for raw Cu 8.4864 and 8.6078, and for the eutectic 8.7312. (1)

Electrical Conductivity of Pulverized Metals under Pressure. (Die elektrische Leitfähigkeit pulverförmiger Metalle unter Druck.) F. SKAUPY & O. KANTOROWICZ. *Metallwirtschaft*, Vol. 10, Jan. 16, 1931, pages 45–47.

A summary of an investigation. The electrical resistance of a compressed metallic powder is higher than that of the compact metal, the difference being greater for hard than for soft metals. The resistance depends both on the amount of pressure and the time of its application, also on the preliminary treatment of the powder. The resistance-pressure curve is non-reversible. With reduced pressure the resistance remains for a time at the minimum, then slowly increases and usually does not return to the original value for no pressure. After repeated pressure applications the resistance of some metals, increases, of others decreases. Some variations from Ohm's law were noted. Fine grained metal powders, with few exceptions, had a higher resistance than coarse grained powders. The temperature coefficient of the resistance is strongly negative with zero pressure, but at higher pressure is negative with rising and positive with lowering temperature. CEM(1)

Physical and Mechanical Properties of Nickel. P. D. MERICA. *Transactions, American Society for Steel Treating*, Vol. 15, June 1929, pages 1054–1059.

The Recommended Practice Committee of the American Society for Steel Treating has published a data sheet covering the physical and mechanical properties of nickel. The information has been compiled by P. D. Merica, and is based on a consensus of the best data available from published and unpublished sources. It is pointed out that since the composition and structure of nickel may vary appreciably, the physical and mechanical values given in the data sheet must be regarded as typical and average values only. Data are presented relative to commercial nickel and to nickel of specially high purity, and an indication is given of the number of determinations upon which any value is based. (1)

Electron Reflection by Passive Iron. I. (Elektronenbeugung an passivem Eisen. I.) E. RUPP & E. SCHMID. *Mitteilungen der deutschen Materialprüfungsanstalten*, Sonderheft 13, 1930, pages 78–80; *Naturwissenschaften*, Vol. 18, 1930, page 459.

The method of study of a surface by allowing a stream of electrons to impinge upon it at a constant angle, varying the speed of the electrons by varying the voltage of the electron source, and noting the maxima in the reflections, has been applied by Rupp and Schmid to single crystals of iron, to the same crystals made passive by HNO_3, to the same oxidized by steam, and to haematite and magnetite, in the hope of showing the nature of the oxide layer on the surface. The reflections from the passive or oxidized surfaces are quite different from those from the iron crystal itself. The maxima in the reflections from the passive layer are inter-related. The constant calculates out to be of the order of 3.4 A. U. Bombardment of the passive layer with fast electrons heats the specimen and alters the layer so that it no longer gives the same reflection curve. The maxima for the passive layer do not match up exactly with those for either Fe_2O_3 or Fe_3O_4. Further work on other oxides and hydroxides is planned. The authors say that their work gives no support for the theory that the passive layer is a 3 dimensional structure of an oxide or hydroxide, nor does it directly prove its nature as a two-dimensional film. HWG(1)

Vanadium, Niobium and Tantalum. A Textbook of Inorganic Chemistry (Ed. by J. Newton Friend), Vol. VI, Part III. SIDNEY MARKS. Charles Griffin & Co., Ltd., London, 1929. Cloth, 6 × 9 inches, 222 pages. Price $10.00.

This volume adds another to the very small group of reference works describing these metals, and that possess true utility. It will serve the chemist more adequately than it will fill the needs of the metallurgist but, of course, has been prepared essentially for the former's use.

It is to be regretted, however, that so many reference works should reflect a most painstaking survey of the literature without any equally strong effort to assemble the data as a critical review. One finds, therefore, repetitions of old misinformation which could be so simply avoided by reference to those research workers and industrial concerns who are in possession of and always eager to transmit the truth. There are, likewise, occurrences of quotations of diametrically opposed data or experiences. For example, at the very outset it is stated that these metals have properties "associated with great hardness" while later describing individually their excellent malleability. In fact, vanadium is referred to as having a hardness of 7.5 on the Mohr scale and unable to be scratched by quartz while just below in the same paragraph is noted that it can be cold-rolled into wire. Another instance is that of the density of niobium which is given as 12.7, while in the immediately following sentence the statement is made that impure varieties show values of 7.06 to 8.4; this would seem to involve rather heavy additions of other elements that could hardly be described as impurities.

The methods of extraction and the uses of the metals are, however, in general, more precisely and completely stated than in most reference works. Among the more serious omissions are the failure to mention the direct reduction of vanadium ore by carbon in the electric furnace now producing a large proportion of the world's supply and the use in Europe of ferro-alloys containing over 50% vanadium. Except in the case of the uses of tantalum, the patent literature seems to have been slighted while in this instance it appears to be very carefully covered. For example, tantalum-gold alloys are mentioned but vanadium-gold alloys do not appear although the complete binary system was patented in 1914.

As noted above the chemistry of the elements and particularly of their inorganic compounds is very admirably described—particularly in respect to the chemical (and physico-chemical) behavior of all 3 metals and the preparation of their compounds. The portions devoted to the heteropoly-acids of the metals and the other very complex compounds, more especially of vanadium, the nomenclature and classification of the salts of vanadium, and the electromotive behavior of niobium and tantalum are particularly to be commended. But one serious chemical error exists. Reference is made to the red amorphous and red crystalline forms of vanadium pentoxide and the instability of the yellow amorphous variety. Actually, the pure oxide is always yellow. When fused, the surface takes on a very dark reddish brown tone but this is an alteration, whether physical or chemical, that influences only a microscopically-thin layer as by the slightest abrasion the yellow color reappears. The commercial oxide, on the other hand, varies from brilliant red to very deep brown due to the presence of impurities and lower oxides.—Jerome Strauss (1)-B-

Electrical Conductivity of Copper (Ueber die elektrische Leitfähigkeit von Kupfer.) G. ELSNER & P. SIEBE (Osnabrucker Kupfer- & Drahtwerk). *Zeitschrift für Metallkunde*, Vol. 22, Dec. 1930, pages 397–401.

Influence of cold working and heat treatment upon electrical conductivity of Cu was investigated. The following materials, the complete analyses of which are given, were employed: American Wirebars with 99.9% Cu, electrolytic copper of 99.8% and 2 brands of Cu refined in the reverberatory furnace of 99.8% and 99.64% purity. The copper wires were annealed at various temperatures from 100–800° C. The deformation range covered 30 to 97%. A maximum of conductivity was established at medium temperatures. This range of maximum conductivity is shifted to lower temperatures by an increasing amount of impurities. The authors suppose a relationship between the structural properties of Cu and the loss on conductivity beyond the peak value mentioned. At higher annealing temperatures, the electrical conductivity of copper increases in contrast with the refined metal which in some cases yields a considerable loss. In general cold working of Cu causes a reduction in electrical conductivity. Differences in resistance due to preceding heat-treatments are more or less annulled by severe cold working according to the purity. The compensating effect of cold work is retarded in the impure grades of refined copper which effect is ascribed to segregation phenomena. In conclusion the authors compare their own findings with former publications on the subject and try to explain contradictions encountered in regard to the location of the peak value and the slope beyond it. EF(1)

PROPERTIES OF NON-FERROUS ALLOYS (2)

Strong Alloys Promote Use of Aluminum Forgings. *Iron Trade Review*, Vol. 86, June 5, 1930, pages 71–74.

Deals with forging practice of the Aluminum Company of America. Alloy 17S is used to a limited extent, 25S and 51S being used for the majority of forgings. Relative forgeability is respectively 3:2:1. Relative machinability is 2:2:1. Heat treated in 2 steps. Solution heat treatment consists in heating at about 960° F. for 12 hrs. and quenching. Aging consists in heating to 300° F. for 18 hrs., if 25S or 51S is used. If 17S is employed, aging takes place at room temperature. As Al forgings are more plastic if only solution heat treated, straightening, compressing, and sizing are done before aging. Heavier hammers than those employed in forging steel are used. Properties and composition of the alloys in the heat treated and aged condition are:

Alloy	Approximate Composition, % Cu	Mn	Mg	Si	Al(min.)	Tensile Strength, lbs./in.²	Yield Point, lbs./in.²	Elongation, % in 2 in.	Brinell hardness, 1000 Kg. Load, 10 Mm. Ball
17ST	4.0	0.5	0.5	...	92.0	55000–63000	30000–40000	18–25	90–105
25ST	4.5	0.8	...	0.8	92.0	55000–63000	30000–40000	16–25	100–120

MS(2)

Some Properties of Silicon-"Aluminium-Bronzes." L. J. BRICE (Woolwich). *The Institute of Metals, Advance Copy* No. 547, 1931, 18 pages.

The effect of Si on the mechanical properties of Cu base alloys containing 5, 7¼ and 10% Al was determined. The alloys were tested as cast, as cast and annealed by heating to 800° C. followed by air cooling, as quenched in oil from 800 or 600° C., and a few as forged. Si contents were as high as 4.5%. With 5% Al the addition of up to 2% Si improves the properties. Further increase of Si increases strength but lowers ductility rapidly. An annealed 5% Al, 3.5% Si alloy has the properties of a 10% Al alloy. The addition of up to 4% Si to the 7¼% Si alloy progressively increases strength and decreases ductility. With more than 3% Si the ductility is so low as to render the alloy useless. The addition of even 1% Si to the 10% Al alloy produces a very low ductility. A microscopic study of the alloys is included. Contains 10 references. JLG(2)

Secondary Aluminum and Aluminum-Alloys and Their Utilization (Umschmelz-aluminium und-Aluminiumlegierungen und ihre Verwendung.) R. STERNER-RAINER. *Zeitschrift für Metallkunde*, Vol. 22, Aug. 1930, pages 269–272.

Qualitative and quantitative survey of the Al-scrap metal market during a long period of time led to the production of 3 grades of secondary aluminum by melting Al-scrap. The latter is converted into the following standards: (1) sand casting alloys with 5–7% Zn, 3–4.5% Cu; (2) chill casting alloys with 2–3.5% Zn and 6–8% Cu; (3) die casting alloys with 2.5% Zn maximum and 6–8% Cu. These alloys worked and heat-treated show a favorable machinability and may be substituted for other more expensive alloys. EF(2)

Report of American Society for Testing Materials Committee B-5 on Copper and Copper Alloys, Cast and Wrought. *Proceedings American Society for Testing Materials*, Vol. 30, Part 1, 1930, pages 407–411.

See *Metals & Alloys*, Vol. 1, Nov. 1930, page 842. (2)

Report of American Society for Testing Materials Committee B-2 on Non-Ferrous Metals and Alloys, with Report of Sub-Committee XV on Die-Cast Metals & Alloys. *Proceedings American Society for Testing Materials*, Vol. 30, Pt. 1, 1930, pages 315–333.

See *Metals & Alloys*, Vol. 1, Dec. 1930, page 898. (2)

Silberit and Ultralumin—Two New Light Alloys. (Silberit und Ultralumin—Zwei neue Leichtmetalle.) *Deutsche Goldschmiede-Zeitung*, Vol. 33, Dec. 20, 1930, page 7.

These 2 alloys are suitable for use in jewelry without plating. Silberit contains Al, Ni and Ag. Ultralumin contains more than 90% Al, Ni, Cu and some rare earth of the thorium group. Exact compositions not given. Ultralumin is especially resistant to sea water. JLG(2)

Some New Industrial Calcium Alloys. (Zur Kenntnis einiger neuer technischer Calciumlegierungen.) JULIUS MEYER & RUTH GORALCZYK. *Zeitschrift für angewandte Chemie*, Vol. 43, Feb. 15, 1930, pages 149–154.

A report on experimental study made at the Department of Chemistry at the University of Breslau on the reactive power of alloys of Ca with Mg, Al and Zn and on the speed of their reacting with other elements. Eight alloys of Ca containing the following percentages of other metals were examined: 37.5, 30 and 20% Mg; 40% Al; 50, 35 and 30% Zn; and 15% Mg and 15% Zn. All were gray-white powders, their brittleness varying with their composition, somewhat sensitive to the action of air and moisture, and even spontaneously combustible. When ignited, CO_2 must be used to extinguish them as the addition of H_2O may even lead to explosions. Ca-Al alloys are most stable in air. These alloys could not be used to dehydrate alcohol. Experiments upon specific gravity, rate of liberating H when treated with H_2O, acids and salts in solution are reported. The nature of the anion is most important in causing such reactions, chloride hastening them and nitrate slowing them. Reducing reactions with Ca-Zn alloys are slower than those with the Ca-Mg alloys. Amalgams of Ca alloys increase the reducing power but little. The use of Ca alloys instead of pure Ca as reducing and raising agents in the making of light-weight concrete is discussed. (2)

A New Silicon-Zinc-Copper Alloy. E. VADERS. *Engineering*, Vol. 130, Sept. 26, 1930, pages 387–388.

Abstract of paper read before the Institute of Metals, Southampton, Sept. 11, 1930. See *Metals & Alloys*, Vol. 1, Dec. 1930, page 898. LFM(2)

Silicon-Copper Alloys and Silicon-Manganese-Copper Alloys. E. VOCE. *Engineering*, Vol. 130, Oct. 3, 1930, pages 441–443.

Condensed from paper read before the Institute of Metals, Southampton, Sept. 11, 1930. *See Metals & Alloys*, Vol. 1, Dec. 1930, page 899. LFM(2)

Bearing Metals. *Machinery*, London, Vol. 35, Feb. 20, 1930, page 671; March 6, 1930, pages 743–744.

The first of these articles gives the composition and properties of yellow metal bearing alloys and copper-tin bearing alloys containing lead. The second discusses the properties and composition of tin-base alloys, lead-base alloys, zinc-base alloys, and lead-base barium alloys. (2)

Aluminium Sheet Production. Part 3, Melting Furnaces. ROBERT J. ANDERSON. *Metallurgia*, Vol. 3, Dec. 1930, pages 53–56.

A description of furnaces used in melting Al and its alloys prior to fabrication into sheets. Oil or gas fired furnaces are usually more suitable than electric furnaces. See *Metals & Alloys*, Vol. 2, Feb. 1931, page 29. JLG(2)

Thermal Treatment is Indispensable for Aluminum and Light Aluminum Alloys. (Les traitements thermiques sont indispensables a l'aluminium et aux alliages legers d'aluminium.) J. SUHR. *Revue de Metallurgie*, Vol. 27, Oct. 1930, pages 563–569.

Aluminum (99.5 Al) is affected in its conductivity by the temperature of working and thermal treatment it might receive. The variations in conductivity obtained were within the range 58.6 and 62.6% of the conductivity of Cu. A pronounced improvement in physical properties, particularly in resistance to repeated impacts, can be produced in Al-Cu alloys by heat treatment. Eight percent Cu alloy soaked for 2 hrs. at 525°, quenched in water and drawn for 15 hrs. at 100° had its resistance to repeated impacts raised from 450 for cast specimens to 9395. A 12% Cu alloy had its impact resistance changed by the same treatment from 54 to 256, while the same thermal cycle resulted for a 4.5% Cu alloy in the increase of the resistance from 402 to 8635. An alloy containing 0.36 Fe, 0.35 Si, 4.17 Cu, and 0.4 Ti soaked for 2 hrs. at 510°, quenched in water and drawn at 190° for 4 hrs. changed the original value of 48 to 6442. Alpax type alloys are not improved by the heat treatment. An alloy containing 4.5 Cu and 0.4 Ti soaked at 525° for 5 hrs., quenched in water and drawn at 150° for 9 hrs. was able to show 18910–28997 as impact resistance instead of the original 312. The new alloy, Eutectal, patented by Rolls-Royce (1.5 Cu, 0.80 Mn, 1.58 Mg_2Si, about 0.25 Si and 0.35 Ti) can be made to give impact resistance of 12000–16000 after soaking for 5 hrs. at 525°, quenching in water, and aging for 5 days at room temperature. The same metal subjected to the above treatment in which aging is replaced with a draw at 150° for 9 hrs., gives an average impact resistance of 25,000. Its resistance in the cast state is 70. Physical properties produced by different treatments are given for all alloys. JDG(2)

Shaping and Annealing Treatment of Copper and Copper-Zinc Alloys. MENDL. *Metal Industry*, London, Vol. 37, Sept. 5, 1930, pages 217–220.

Abstracted from an article "Spanlose formung und glühbehandlung von Kupfer und Kupfer-Zink-Legierungen" in *Metallwirtschaft*, Vol. 9, No. 12. Hot deformation of Cu can be carried out over a wide temperature range, 700° to 900° C. Choice of temperature is guided by the following principles: The greater the surface in relation to volume, the more rapidly the material will cool during working. Although easier to heat up, it must be kept at higher temperature. The influence of speed of deformation is varied. For cold deformation annealed material is used. Clean annealing is important. Most common method consists of air-tight packing of the metal in an annealing pot. Material to be annealed should be wrapped in Cu. Grain size of normally annealed Cu is 0.01–0.08 mm. diameter. When overheated it rises to 0.1–0.4 mm. Role of impurities in Cu. Most important alloys of Cu are those with Zn. Equilibrium diagram shows the 63–37 alloy to be an α-brass but that the β-crystals form at about 700° C. If Cu content falls to about 62% β-crystals form at 600° C. α-Crystal is readily worked cold. Admixture of Pb exerts considerable influence on ease of hot working. Origin of the stresses. Stresses may be removed by deformation opposed to previous cold deformation and by heating. VSP(2)

Mechanical and Physical Properties of Magnesium Alloys. S. L. ARCHBUTT (National Physical Laboratory, England). *First Communications of the New International Association for the Testing of Materials.* Group A. Zurich, 1930, pages 251–256, 7 references.

Compilation of properties, in some cases up to 500° C. of pure Mg alloys with 6% Al, 3% Cu, and with 4.4% Zn plus small amounts of Al and Cu, in the wrought condition and, at ordinary temperatures, of a variety of cast alloys of Mg with various amounts of Zn, Al, Cu, Cd, Mn as alloying elements. HWG(2)

Melting Points of the System Tungsten–Rhenium. (Ueber die Schmelzpunkte im System Wolfram–Rhenium.) KARL BECKER & KURT MOERS. *Metallwirtschaft*, Vol. 9, Dec. 26, 1931, pages 1063–1066.

Contains 10 references. W and R are the 2 metals with highest melting points. The melting points of their alloys were determined by the method of Agte and Alterthum and they were examined microscopically and by X-rays. An intermetallic compound W_2R_3 with m. p. 3280° abs. is formed. This forms a eutectic with 50 atom % of R, m. p. 3165° abs., and with 67 atom % R, m. p. 3095° abs. W_2R_3 is slightly soluble in W with a 1.4% contraction of its lattice. It was not found to be soluble in R, but both W and R are soluble in W_2R_3. Seven photomicrographs of W-R alloys are given. CEM(2)

Deflection Due to Temperature of Bi-Metallic Strips of Any Curved Shape. (Temperaturausbiegung von Bimetallstreifen beliebiger Kurvenform.) K. BECKER. *Forschung und Technik*, 1930, pages 340–348.

The locus of the free end of a bi-metal strip, which is clamped rigidly on one end and has any given shape, is determined as a function of shape and temperature. The function is theoretically derived and simplified for the case of a small increase of temperature (initial deflection). The derived functions are evaluated for the straight strip, half-circle and full circle and the temperature-sensitivity is defined. The initial deflection and the temperature-sensitivity are calculated for one leg of a U-shaped strip, held in the U-point. This problem is often met with in practice, as these arrangements are used for thermal relays. An example is shown where a straight strip is heated until it assumes the shape of a full circle. Calculation and test show a close agreement. Ha(2)

Thermal Properties of Different Groups of Alloys. (Die thermischen Eigenschaften verschiedener Legierungsgruppen.) A. SCHULZE. *Giesserei-Zeitung*, Vol. 27, Apr. 1, 1930, pages 177–184.

A description of thermal expansion (dilatometry) and its relation to the constitution of alloys and the method of investigation. Discusses the relations between heat conductivity and constitution. Notes on magnetic properties of alloys and X-ray analysis by which the fine structure of alloys is rendered visible are included. (2)

Contribution to the Knowledge of the Elastic Properties of Light Metals. (Beitrag zur Erkenntnis der elastischen Eigenschaften der Leichtmetalle.) H. SIEGLERSCHMIDT. *Mitteilungen der deutschen Materialprüfungsanstalten*, Vol. 14, 1930, pages 40–44.

High Duty Cast Iron. (Hochwertige Gusseisen.) GEBRÜDER SULZER (Winterthur, Switzerland). *First Communications of the New International Association for the Testing of Materials.* Group A. Zurich, 1930, pages 49–63.

A cast alloy of about 1% C, $2^3/_4$% Si, 1% Mn, free from graphite, cast in a $^3/_4$" plate, has a tensile strength of nearly 100,000 lbs./in.^{2} This is the strength of the pearlitic ground mass of high-strength cast iron. The addition of alloying elements does not materially alter the strength of the ground mass itself, though they generally increase the hardness. The strength of the cast iron of course depends both on the matrix and the amount and distribution of graphite. The strongest graphite containing alloy of hardness below 310 Brinell (still machinable) of a series of 20 cast irons was one of 2.66% total C, 3.10% Si, 0.32% Mn, 0.08% P, 0.02% S, which had 69,500 lbs./in.^{2} tensile strength, 269 Brinell, 100,000 lbs./in.^{2} bending strength, 0.6" deflection (apparently on a 1.2" diameter bar, $23^1/_2$" centers). One with $2^1/_2$% total C, 3% Si gave nearly as high figures. Still lower carbon irons have higher tensile strength, but are more likely to have internal defects. Several highly alloyed cast irons containing Ni, Cr, W, Mo, V and Ti were tested (one contained a total of $4^3/_4$% of these elements), but were not superior to the unalloyed irons cited, in static properties. They may, however, be more wear-resistant. HWG(3)

The Relative Merits of Some Different Alloy Steels with Respect to Certain Mechanical Properties. BRADLEY STOUGHTON & WILBER E. HARVEY. *Proceedings American Society for Testing Materials*, Vol. 30, Pt. 2, 1930, pages 241–277.

Bessemer Steel, Its Properties and Use. J. R. MILLER. *Blast Furnace & Steel Plant*, Vol. 18, Oct. 1930, pages 1602–1605.

Properly made Bessemer steel with P not over 0.10% has greater stiffness and higher tensile strength than open-hearth steel with the same C content and possesses superior machining, threading, welding and wear-resisting qualities. Its principal fault is brittleness under shock and in cold working, this being particularly marked in the heavy rolled sections. It is, therefore, necessary to be sure that it is applied only where it will fulfill the requirements. Tabulates the purposes for which Bessemer and open-hearth steels are used, giving sections and sizes and the analyses of the principal Bessemer grades. It would seem, as far as the bar sizes are concerned, Bessemer steel should hold an almost equal place, in point of quantity, with open-hearth steel if it were available in proper quality in such quantities. Physical Properties of Hadfield Steel. V. N. SVECHNICOV. *Heat Treating & Forging*, Vol. 16, July 1930, pages 881–886, 892.

Translated by T. P. Tolmachoff from the *Journal of the Russian Metallurgical Society*, 1929, No. 1. Contains some foot-note additions by the author. See *Metals & Alloys*, Vol. 1, Jan. 1930, page 338. MS(3)

The Change of Density in Iron and Steel Caused by Cold-Working and by Tempering. K. TAMARU. *Science Report, Tohoku Imperial University*, Series I, Vol. 19, 1930, pages 437 to 448.

The change of density of Fe and steel as the result of cold-working and of tempering was investigated. The density of Armco Fe decreased 0.12% by cold-working of 77.6% reduction in area. In tempering this Fe, a maximum at 150° and a minimum at 400° were observable and at higher temperatures the density increases, till it resumes the value before rolling. The maximum is due to the stress-release and the minimum is to be attributed to the increase of stable internal stress at the cost of the unstable one during tempering. The increase of density at a higher temperature shows the recovery of the original state before rolling. Remelted Armco Fe did not show such a change of density. In the case of 0.1% C steel, the amount of the maximum and the minimum is less. Their magnitude diminishes with the increase of C content, being hardly traceable in 0.2% C steel. This means that it is difficult to remove the internal strain in steels in which hard cementite is present in a large amount. KT(3)

CORROSION, EROSION, OXIDATION, PASSIVITY & PROTECTION OF METALS & ALLOYS (4)

Corrosion Symposium a Feature of T. A. P. P. I. Meeting. *Chemical & Metallurgical Engineering*, Vol. 37, March 1930, pages 155–156.

Corrosion is particularly troublesome in sulphite mills. J. D. Miller, Chairman of the committee on corrosion problems of the Technical Association of the Pulp and Paper Industry, reported at the meeting held Feb. 17–20, 1930, that the average value of the corrosion loss was $98.75/year/ton daily production. This is based on answers to a questionnaire. Attention is being given to the ferrous alloys. Those of the 18–8 Cr-Ni type, with or without Mo, when properly prepared, are the best metals offered to date for resistance to sulphite corrosion. Andreas Christensen described the results obtained by him in a mill test of 2 alloys. The first was a steel containing 25–30% Cr, 1% Mn, 0.5% Ni, 0.5% Si, 0.25% C. The second belonged to the "18–8" group. Alloy No. 1 has given more than 2 years of continuous service without attack as parts of relief valves for a digester. Pipe made from No. 2 placed in a relief line next to the same digester has been in use for 15 months without wear. Because of these results, many small fittings and pipes are being changed from Cu and bronze to a ferrous alloy. The initial cost of the fittings made from these alloys is about twice that of bronze. Walter M. Mitchell stated that centrifugally cast Cr-Ni-Mo alloy tubing of large size is a commercial possibility in the near future. Fabrication of a full size digester of this alloy is a possibility. Riveting is to be preferred to welding as a means of construction. T. H. Nelson stated that an alloy with a residual Fe content of not more than 65% gives the most consistant results in respect to resistance to sulphite corrosion. The most suitable metal is one containing 20–25% Cr, 8–10% Ni, with the addition of Si or Mo. MS(4)

The Corrosion of Early Chinese Bronzes. WILLIAM F. COLLINS (Anglo-French China Corp. and S. Pearson and Son). *The Institute of Metals, Advance Copy* No. 548, 1931, 25 pages.

The probable mechanism of the formation of patina on early Chinese bronze is discussed in light of the corrosion studies made in England and the mechanism of mineral formation. Sulphur was probably not a factor in the corrosion of the Chinese bronzes. The ancient Chinese bronzes are unique in containing appreciable quantities of Pb. The analyses of a large number of these bronzes are given. The data also include the probable period of origin. Contains 30 references. JLG(4)

Protective Coatings for Aluminum and Alloys Present Problem. *Automotive Industries*, Vol. 62, Apr. 12, 1930, pages 583–584.

Abstract of a paper on "Some Recent Developments in Protective Coatings of Aluminum and Some of Its Alloys," by H. Sutton, presented at a meeting of the British Electroplaters' and Depositors' Technical Society. See *Metals & Alloys*, Vol. 1, Aug. 1930, page 690. GN(4)

Chlorination Prevents Slime Fouling of Condensers. *Electrical World*, Vol. 96, Nov. 15, 1930, page 906.

Adhesion of slime to condenser tubes and the consequent decrease in the condenser vacuum and rate of heat transfer may be prevented by chlorination of the circulating water as proved by experiments conducted by the Northern Indiana Public Service Co. and by the Public Service Electric & Gas Co. The investigation brought out the following: (1) that slime adhesion to condenser tubes can be prevented by chlorination, (2) chlorination results in the depositing of a hard scale in the tubes which must be removed by cleaning by other means than rubber plugs, (3) when circulating water is treated with bleaching powder there is not so much scale deposited on the tubes as with the chlorine gas treatment, (4) chlorination does not cause corrosion or excessive loss in weight of condenser tubes, (5) uniform absolute pressure close to standard performance can be maintained with much less total cost for tube cleaning. A chart gives the performance of a condenser, the circulating water for which was treated alternately with Cl gas and bleaching powder in the East Chicago plant of the Northern Indiana Public Service Co. Tests Yield Data for Applying Chrome Nickel Steels. *Machine Design*, Vol. 2, June 1930, pages 43–44.

Discussion of corrosion resistance under varying conditions and the machinability of KMI and KA2 with a chart showing comparative examples of resisting power of steels to corrosion. Tables give losses by exposure to dilute solutions and to air and water as well as losses by exposure to various chemicals. (4)

"Nimol" a New Corrosion Resisting Cast Iron. *Canadian Mining Journal*, Vol. 51, Dec. 12, 1930, page 1204.

This new alloy containing 75% ordinary cast iron, 4% chromium and 21% Monel metal has proved its usefulness in certain parts of marine steam boilers, as supports in metallurgical furnaces, and where resistance to sulphuric and hydrochloric acids is required. It is very useful in pumps of various kinds. WHB(4)

Corrosion of Tin and Its Alloys. C. L. MANTELL. *Sheet Metal Industries*, Vol. 3, Feb. 1930, page 596; June 1930, pages 168–170.

A paper before the American Institution of Mining and Metallurgical Engineers. Acetylene gas does not attack Sn. Carbon bisulphide tarnishes polished Sn surfaces. Many chlorinated and halogenated hydrocarbons corrode Sn. Formaldehyde, when oxidized to formic acid corrodes Sn. Sn or its alloys should not be used in any developing work because of a fog it creates in developed plates. Acid beer acquires turbidity in contact with Sn. Fresh milk does not affect Sn but sour milk corrodes it. In canned goods, chemical action will continue until Sn is dissolved entirely and then electrolytic action will be added because of the exposure of Sn and Fe in electrolyte. Discoloration is largely due to sulphides and sulphocompounds. Enamelled coatings over the Sn plate have been found to be not continuous so that chemical action is localized at points and is more rapid than if distributed over the entire surface of the can. AWM(4)

Corrosion Resisting Alloys for Pulp and Paper Mills. W. M. MITCHELL. *Paper Trade Journal*, Vol. 90, Feb. 20, 1930, pages 155, 156.

A paper presented at the Feb. 1930 meeting of the Technical Association of Pulp and Paper Industry. The selection of metals for the construction of plant equipment for use in handling corrosive materials in the problem affecting many processes and is always one of extreme importance. Corrosion phenomena and corrosion in paper mills are considered. The use of Ni bearing alloys such as 18/8 chrome nickel, KA2, Allegheny metal, 18/8/3 Cr-Ni-Mo, V4A, KA4 and Monel metal are discussed. (4)

The Resistance of Alloys to Sulfite Corrosion. J. D. MILLER. *Paper Trade Journal*, Vol. 90, June 6, 1930, pages 91–92.

A discussion of the preliminary results in sulphite digesters of Cr and Ni-Cr steels. (4)

Recent Developments in Embrittlement Research. F. G. STRAUB. *Power Plant Engineering*, Vol. 34, June 15, 1930, pages 686–687.

Sulphate prevents embrittlement only when it is present in amounts which will cause solid sodium sulphate to form in seams. Studies at pressures up to 1300 lbs. indicate that the present 3 to 1 ratio recommended by the A.S.M.E. code will be safe for practically all boiler pressures. The causes for boilers, which do not have sulphate ratios, not cracking is discussed. (4)

Corrosion of Aluminum Cast Alloys. (Ueber die Korrosion von Aluminium-Gusslegierungen.) R. STERNER-RAINER. *Zeitschrift für Metallkunde*, Vol. 22, Oct. 1930, pages 357–362; discussion; 17 references.

The writer tabulates in a clear fashion the corrosion resistance of pure Al, KS-Seewasser, Silumin, German Alloy, American Alloy and Navy Bronze against the attack of some 25 inorganic salt solutions and against a dozen various food stuffs as honey, lactic acid, mustard, whisky, etc. It is pointed out that all those elements which are suitable for separating Fe from Si, which impurities are always present, re-establish to a certain degree the corrosion stability of pure Al. Whether films are able to stop the starting corrosion could not definitely be settled although additions of Sb and Bi give some evidence in this regard. All the other additions, particularly Cu, are only liable to decrease the corrosion resistance of pure Al. The nature of atmospheric corrosion and of natural waters is considered and the favorable behavior of Silumin and KS-Seewasser mentioned. Stress is laid on the fact that even Cu-alloys can often be replaced by Al-cast-alloys. The corrosion resistance may be furthermore improved by paints, tars, varnish and similar coatings. The paper was presented at the Berlin Meeting of the Deutsche Gesellschaft für Metallkunde, March 1930. EF(4)

Salt Spray Corrosion Tests on Electrically Deposited Zinc-Cadmium Alloys. LAWRENCE E. STOUT & CHARLES L. FAUST (Washington Univ., St. Louis). *Metal Industry*, N. Y., Vol. 28, Aug. 1930, pages 381–383.

Results show that same Zn-Cd alloys electrically deposited on Fe from alkali cyanide solutions are superior to electrically deposited Cd as protection against rusting. Increase in resistance to corrosion is obtained when alloy contains as little as 0.5% of Zn and is constant until Cd is increased to 80%. Below this Cd concentration alloys become poorer as rust proofing agents. Alloys with 60% Cd and the rest Zn offer rust protection nearly equal to that offered by Cd. Zn-Cd alloys display superior adhesion to base metal than either Zn or Cd alone. Zn-Cd alloys can easily be buffed to luster and clear bluish metallic color. VSP(4)

Rust Resistance of Iron and Steel Sheets. W. H. MELANEY. *Heat Treating & Forging*, Vol. 16, July 1930, pages 887–888; *Blast Furnace & Steel Plant*, Vol. 18, Sept. 1930, pages 1471–1472.

Describes manufacture of wrought Fe by the puddling process, the purpose being to show that wrought Fe is superior to steel with respect to corrosion resistance because of the coating of slag about the particles of Fe. MS(4)

On the Passifying Effect of Red Lead. (Ueber die passivierende Wirkung der Bleimennige.) E. MAASS & E. LIEBRIECH. *Korrosion und Metallschutz*, Vol. 6, Aug. 1930, pages 178–181.

On the strength of their experiments and based on theoretical considerations the authors doubt the passifying effect of minium by loading the surface of Fe with oxygen and are inclined to believe that the protection is merely due to the alkaline character of lead oxide. The formation of lead soap is supposed to affect physical properties of surface film. EF(4)

Applying Protective Coatings on Metal. H. SUTTON. *Metal Cleaning & Finishing*, Vol. 2, Jan. 1930, pages 43–44.

From paper read before Electroplaters' & Depositors' Technical Society. See *Metals & Alloys*, Vol. 1, Aug. 1930, page 690. MS(4)

The Local Current Theory of Corrosion and Passivity. (Zur Lokalstromtheorie der Korrosion und Passivität.) F. TOEDT. *Zeitschrift für physikalische Chemie*, Vol. 148, June 1930, Abt. A, pages 434–440.

Corrosion in weak acid, weak alkali or neutral solutions is dependent upon local currents whose size depends on the depolarization of O_2 at the cathode. The significance of local action between the metal and its oxide coating is discussed with relation to passivity and its periodic occurrence. (4)

The Corrosion of Lead and Its Significance in the General Interpretation of Corrosion. (Die Korrosion des Bleis und ihre Bedeutung für die allgemeine Erkenntnis der Korrosion.) M. WERNER (I. G. Farbenindustrie). *Zeitschrift für Metallkunde*, Vol. 22, Oct. 1930, pages 342–347.

Grain size plays the same role in Pb corrosion as in all metals and alloys. The addition of other metals is only liable to improve the corrosion resistance if passification takes place. However, the occurrence of a eutectic in the system Pb–impurity upsets the favorable influence of the addition. Cold work does not affect the corrosion stability of Pb because of the great recrystallization velocities met at even ordinary temperatures. The best grade of corrosion proof Pb contains no O. The lack of proper methods of testing, complicating the interpretation of Pb corrosion, is pointed out and the application of new methods urged. The paper was presented before the Deutsche Gesellschaft für Metallkunde, Berlin 1930 and includes a long discussion. EF(4)

The Open-Air Corrosion of Copper. Part II. The Mineralogical Relationships of Corrosion Products. W. H. J. VERNON & L. WHITBY. *Engineering*, Vol. 130, Nov. 14, 1930, pages 631–632.

Condensed from paper read before the Institute of Metals, Southampton, Sept. 11, 1930, *Metals & Alloys*, Vol. 1, Nov. 1930, page 843. LFM(4)

Corrosion of Different Types of Corrosion Resistant Steels by Common Acids. (Attaque de divers types d'acier inoxydables par les principaux acides usuels.) M. SAUVAGEOT & L. LAUPRETE. *Revue de Metallurgie*, Vol. 27, July 1930, pages 362–367; *Chimie et Industrie*, Vol. 23, Mar. 1930 (Special issue), pages 227–231.

Short time (not over 5 hrs.) corrosion tests were made on corrosion resisting steels of the following types: 13% Cr, 8% Ni-20% Cr, 8% Ni-19% Cr, and 32% Ni. Temperature used was 15° and 80° C. with acid concentrations up to 65%. All steels were annealed. High Cr and Ni-Cr steels are very resistant to HNO_3. In HCl and H_2SO_4, they dissolve at the ratio depending on acid concentration, with almost the same speed as common steels. The superiority of Ni-Cr over the Cr type is observed only at low acid concentration. High Ni steel resists H_2SO_4 and HCl better than all the others but is rapidly attacked by HNO_3. JDG(4)

Heat Enduring Metals for Furnace Construction. B. J. SAYLES (Calorizing Co.). *Fuels & Furnaces*, Vol. 8, May 1930, pages 699–701; June 1930, pages 835–838, 844–845, 864.

Commercially available heat enduring materials include Cr plated mild steel, calorized mild steel, and the following alloys: (a) 60% Ni, 20% Cr, 20% Fe; (b) 35% Ni, 15% Cr, 50% Fe; (c) 8% Ni, 20% Cr, 72% Fe; (d) 8% Ni, 30% Cr, 62% Fe; and (e) 18% Cr, 82% Fe. Cr plating has several disadvantages—the porosity of the deposit, and the difference in coefficient of expansion of the Cr film and of the steel. The Fe-Al alloy formed in calorizing is immune to oxidation up to 1650° F. Tubular materials are treated by the powder method, while irregularly shaped articles are processed by the dip method. It is customary to fabricate parts before calorizing, as doing so after treatment injures the alloy surface. It is not feasible to weld calorized parts. In the case of the ferrous alloys listed, the content of C and other elements is very important in determining the useful life of the alloys. Cites W. H. Hatfield's results of oxidation tests in various atmospheres and at various temperatures (*Journal of the Iron & Steel Institute*, Vol. 115, 1927, pages 483–508). These indicate that the usefulness of a 13% Cr-87% Fe extends to about 1650° F., while an alloy of the (c) type might be used slightly beyond that temperature. A test carried out in a H_2S atmosphere at 1200° F. showed that resistance to S corrosion increased with increase in Cr content. Calite "B" has a maximum safe working temperature of 1800° F., and the safe load at this temperature is 2000 lbs./in.^{2} Its coefficient of linear expansion is 0.000005° F., sp. gr., 7.49; thermal conductivity, 5.5 B.t.u./hr./ft.^{2}/ft. thickness/° F.; Brinell hardness, 340. Discusses design of heat enduring structures. MS(4)

The Constitution of the Cadmium-Rich Alloys of the System Cadmium–Silver. P. J. DURRANT (Selwyn College, Cambridge). *The Institute of Metals, Advance Copy* No. 549, 1931, 15 pages.

Alloys containing up to 40% Ag were studied microscopically and by means of heating and cooling curves. There are 3 peritectic lines, and 3 solid solutions in this area. The solid solubility of Ag in Cd is 6.0% at 343° C., and 5.2% at 250° C. The second solid solution includes from 18 to 33.5% Ag, the third more than 36% Ag. Contains 6 references. JLG(5a)

Practical Application of the Sulphur Prints of R. Baumann. (Praktische Anwendung des Schwefeldruckes von R. Baumann.) HUGO PATSCH. *Giesserei*, Vol. 17, Aug. 29, 1930, pages 853–854.

The sulphur print method of Baumann is used for making prints of chilled and gray Fe casting surfaces containing fine cracks. Repeatedly printing the same spot gives prints which are progressively weaker. By moistening the cracked surface with dilute H_2SO_4 and using AgBr-paper which has been soaked in 5% H_2SO_4 a sharp, dark print is again obtained. (5a)

Investigations of the Mechanism of the Solution of Cementite in Carbon Steel and the Influence of the Heterogeneity of the Material. The Equilibrium Diagram Iron-Vanadium (Zur Kenntnis des Zweistoffsystems Eisen-Vanadin.) F. WEVER & W. JELLINGHAUS. *Mitteilungen Kaiser Wilhelm Institut für Eisenforschung*, Vol. 12, 1930, Report 164, pages 317–322; *Stahl und Eisen*, Vol. 50, Dec. 18, 1930, page 1788.

The equilibrium diagram Fe-V was newly established by thermic-microscopic, magnetometric and X-ray investigations. The crystallization starts with the formation of cubic space centered α-solid solutions, the parameter of which increases with the V content. The field of the cubic face centered γ-solid solution is closed and extends up to 1.1% V. The solid solution with 48% V transforms to the compound FeV at 1234° C., as revealed by thermic, microscopic and X-ray examination. This compound dissolves Fe as well as V in excess. The Curie point of Fe is raised first, but essentially lowered with higher contents of vanadium. GN(5a)

Structures of Solid Solutions of Iron with Beryllium and Aluminum. (Ueber den Aufbau der Mischkristalle des Eisens mit Beryllium und Aluminium.) F. WEVER & A. MÜLLER. *Zeitschrift für anorganische und allgemeine Chemie*, Vol. 193, Oct. 4, 1930, pages 337–345.

Thermal and microscopic study of Fe-Be and Fe-Al alloys led to a new determination of the Fe side of the equilibrium diagram. Both systems have completely closed γ-fields. Solid solutions of α-Fe with Be and Al are formed by atomic substitution; the same structure is assumed for the solid solutions of γ-Fe with both elements. The unusual behavior of C in alloy formation with Fe has no parallel in the elements Be and Al. (5a)

The Course of Reactions Between Graphite and Oxides as Well as Between Heavy Metal Carbides and Oxides. (Ueber den Verlauf der Reaktionen zwischen Graphit und Oxyden sowie zwischen Schwermetallkarbiden und Oxyden.) O. MEYER. *Archiv für Eisenhüttenwesen*, Vol. 4, Oct. 1930, pages 193–198. *Stahl und Eisen*, Vol. 50, Nov. 13, 1930, page 1619.

The investigation was undertaken to determine the stability of materials of crucibles of various mixtures of carbides and oxides which was done by measuring the pressure of reaction. The systems graphite–silica, graphite–MnO, graphite–alumina and graphite–silica–iron were examined. Crucibles of the above mixtures were heated in a C spiral-vacuum furnace, the CO pressure was measured and plotted in diagrams against the temperature. The oxides of Mn, Si and Al easily evaporate, thus leading to wrong values of the pressure. MnO, SiO_2 and also Al_2O_3 are reduced at temperatures above 1550° C. Powdered carbides and oxides react at temperatures where the compact crucibles do not yet show any reaction. Mo_2C, W_2C, WC and SiC show weaker reactious with oxides than graphite. Mixtures of chromium and tungsten carbides, which are rather resistant to O, do not show the same resistivity to oxides. Titanium nitride reacts strongly with oxides. GN(5a)

A Thermodynamic Study of the Phasial Equilibria in the System Iron-Carbon. CHU-PHAY YAP. *American Institute of Mining & Metallurgical Engineers, Technical Publication* No. 381, 1931, 26 pages.

The Fe-C diagrams determined by several investigators have been replotted, using instead of weight % C, molal concentration of C and Fe_3C. The topography of these diagrams indicate that just before the liquid transforms to δ Fe, C exists in solution as the element, while in liquid Fe containing a larger amount of C it exists as the carbide Fe_3C. Upon solidification, the Fe_3C decomposes to yield a solution of elementary C in γ-Fe. The liquidus of Ruer and Goerens, and a solidus drawn as a straight line from 0.18% C at the peritectic temperature to about 1.7% at the eutectic temperature probably represents the real equilibria based on the diagrams as replotted and application of the available thermodynamic data. The solidus determined by Honda and others by heating, probably does not indicate the same line as determined by cooling from the liquid condition. A thermodynamic analysis indicates the heat of fusion of pure Fe as about 64 cal./g., which is in agreement with recently determined values and not with the values of 48 and 49.4 given in the International Critical Tables. The heat of transformation of γ to δ-Fe is calculated as about 2 cal./g. Contains 21 references. JLG(5a)

Influence of Dissolved Carbide on the Equilibria of the System Iron-Carbon. CHU-PHAY YAP. *American Institute of Mining & Metallurgical Engineers, Technical Publication* No. 382, 1931, 19 pages.

In a previous paper (*Technical Publication* No. 381) the author showed by thermodynamics that the solidus in the Fe–C system should be a straight line, as found by English investigators. Others have found a curved solidus. The straight line has usually been found by cooling from the molten condition while the curved line has been found on heating. Honda and Endo determined the solidus by susceptibility measurements. Their data are replotted on a larger scale and, from the course of the curves, it is concluded that the indicated melting point is too low because the Fe_3C has not been decomposed. It is concluded that when an Fe-C alloy is heated from room temperature, as austenite is formed the Fe_3C dissolves to form a solution of Fe_3C in γ-iron, and, dependent on the rate of heating and other factors, part of the Fe_3C decomposes to give a solution of C in γ-iron. The amount of dissociation of Fe_3C influences the temperature at which melting begins. As the alloys are cooled from the melt the C is in solution in the γ-iron as elementary C. With a given C percentage the alloy containing undecomposed Fe_3C in solution will have the lower melting point. Contains 14 references. JLG(5a)

On the Equilibrium Diagram of the Iron–Vanadium–Carbon System. S. OYA. *Kinzoku no Kenkyu*, Nov. 1930, pages 615–634; *Science Report of the Tohoku Imperial University*, Series I, Vol. 19, 1930, pages 449–472.

Vogel and Tammann's diagrams of V–Fe system were combined and utilized. Fe and V form a continuous series of solid solutions. The A_4 point of Fe is lowered and the A_3 point is raised until the α- and δ-irons unite at about 2.5% V, forming a loop. The probable equilibrium diagram of V–C system was obtained by Osawa and the present writer by means of X-ray analysis and microscopic investigation. There exist 2 carbide phases β and ϵ, consisting mainly of compounds V_8C and V_4C_3, respectively. α-Phase consists of V dissolving C. By thermal analysis, liquidus surface, binary eutectic curves E_1E, E_2P, E P, peritecto-eutectic point P, ternary eutectic point E were determined. By X-ray analysis it was found that the ϵ-phase with the face-centered cubic lattice is present in high C alloys; the β-phase with hexagonal close packed lattice is present in low C alloys; and α-phase with body-centered cubic lattice is present in high V and low C alloys. The microscopic investigation was also applied mainly to high C and high V alloys. The ϵ- and β-phases can be seen distinctly without etching; the primary ϵ-phase reveals the globular dendrite, while the primary β-phase crystallizes in the columnar form. The β-phase is not colored by boiling sodium picrate, but the ϵ-phase is colored slightly by long heating. By etching with the picric acid, the β is not changed in color, though the crystal boundaries are clearly revealed; the ϵ is also hardly etched, but colored slightly bluish gray after long etching. The equilibrium diagram of Fe–V–C system thus obtained is shown in the figure, from which the following facts are deduced. (1) No ternary compound exists in this system but 5 liquidus surfaces for the γ, α, Fe_3C, ϵ and β phases exist. (2) The following binary eutectic and peritectic reactions exist in this system: melt $\longrightarrow \gamma + Fe_3C$, melt $\longrightarrow \gamma + \epsilon$, melt $\longrightarrow Fe_3C + \epsilon$, melt $\longrightarrow \alpha + \epsilon$, melt $\longrightarrow \epsilon + \beta$, melt $\longrightarrow \alpha + \beta$ and δ + melt $\longrightarrow \gamma$. (3) In this system, the following 2 ternary eutectic reactions and also a peritecto-eutectic reaction take place: (1) melt $\longrightarrow \gamma + Fe_3C + \epsilon$, (2) melt $\longrightarrow \alpha + \beta + \epsilon$, (3) δ + melt $\longrightarrow \gamma + \epsilon$. The composition and temperature of these non-variant points are as follows:

(1)	3.4% V	4.2% C	1122°
(2)	about 35.0% V	1.0% C	....
(3)	7.0% V	2.3% C	1330°

(4) In the region of the γ-phase, there exist 3 solubility surfaces, in which α, ϵ and Fe_3C begin to separate respectively, and 3 binary eutectoid curves along which the reactions $\gamma \longrightarrow \alpha + \epsilon$, $\gamma \longrightarrow \alpha + Fe_3C$ and $\gamma \longrightarrow Fe_3C + \epsilon$ take place. The Question of the Origin of Meteorites. (Zur Frage des Ursprungs der Meteorite.) WILLIAM D. URRY & W. KOECK. *Zeitschrift für Elektrochemie und angewandte physikalische Chemie*, Vol. 36, Sept. 1930, pages 727–732.

The question of the origin and age of meteorites is discussed by the authors in the light of experiments on the helium and radium contents of a number of meteorites. They conclude that meteorites are of the same origin as the planets, having sprung from the mixture of which the sun consists. The oldest meteorites that have remained unchanged are contemporaneous with the earth. OWE(5a)

An Investigation of Type-Metals. Part 4. On the Equilibrium Diagram of the Lead–Antimony–Tin System. NOBUTOSHI AOKI & SHOJIRO WAKI. *Naikaku Insatsu-kyoku Kenkyujo Chosa Hokoku (The Report of the Research Laboratory, Government Printing Bureau, Japan)*, No. 21, Nov. 1930, pages 1–36.

The primary crystallization points and the transformation points for about 200 alloys of the Pb–Sb–Sn system were determined by means of thermal and microscopic analyses, and the solidus, by differential thermal analysis. From the results thus obtained, 13 sectional diagrams of the system were constructed, and from these diagrams the space model of this ternary system was also constructed. Fig. 1 shows a diagram obtained by projecting the space curves in this model onto the base of a triangular prism. As we see in the diagram, this system contains 4 liquidus surfaces from which α-, β-, γ- and δ-ternary solid solutions separate from the homogeneous melt. Along the boundary curves $r'o'_1$, and $s'o'_2$ peritectic reactions take place. Along the boundary curves u',o'_1, o'_1,o'_2 and o'_2t' binary eutectic reactions take place. Hence, points, o_1 and o_2, correspond to a ternary eutectic point and a peritecto-eutectic point respectively. The former point lies on the composition, 85% Pb, 11.5% Sb and 3.5% Sn, and its temperature is 240° C., and the latter point lies on the composition, 40% Pb, 2.5% Sb and 57.5%% Sn, and its temperature is 189° C. For

determining the points, O_1 and O_2, the microstructures of 156 specimens containing various compositions were observed after being heated for 50–500 hours, in several temperatures and quenched in water. Fig. 2 shows the isothermal curves surfaces. The authors have also constructed the more detailed curves for the composition range of actual type-metals such as 50–100% Pb, 0–30% Sb and 0–20% Sn. TS(5a)

An Investigation of Type-Metals. Part 5. On the Brinell-Hardness of the Lead–Antimony–Tin Alloys. NOBUTOSHI AOKI & SHOJIRO WAKI. *Naikaku Insatsu-kyoku Kenkyujo Chosa Hokoku (Report of Research Laboratory, Government Printing Bureau, Japan)*, No. 21, Nov. 1930, pages 47–62.

Fourteen specimens each of Pb-Sb and of Pb-Sn alloys containing various compositions and 12 specimens of Sb-Sn alloys were prepared by casting in a metallic mold from temperatures 100° to 200° C. above the melting point of each alloy, and finished to the size of 20 × 20 × 30 mm. with emery paper. The Brinell hardness of each alloy was determined, and the hardness-composition curves of each series were drawn. From these curves, we can see that in the Pb-Sb alloys the hardness ascends as the Sb content increases,

while in Pb-Sn alloys 2 maximum points are observable at 64% Sn and 70% Sb. Brinell hardness was also determined for 82 ternary alloys of the Pb–Sb–Sn system, and from the results thus obtained the isohardness curves were constructed in the composition range of actual type-metals, such as 50–100% Pb, 0–30% Sb and 0–20% Sn, as shown in the figure. The change in hardness due to composition was attributed to the separation of new phases in each alloy. TS(5a)

Sulphur Print Tests. L. E. BENSON. *Electrician*, Vol. 106, Jan. 2, 1931, pages 4–5.

The value of the sulphur print test, and its simple operation and sensitiveness are pointed out. Sulphur prints can be applied to practically all the usual steels of engineering importance. Steels of high chromium content, such as stainless steels and some non-magnetic steels are exceptions. WHB(5a)

Structure & X-ray Analysis (5b)

Texture of Metals after Cold Deformation. FRANZ WEVER (Kaiser-Wilhelm-Institut für Eisenforschung). *Preprint, American Institute of Mining & Metallurgical Engineers*, 1931, 25 pages.

A method is described for the determination and description of the orientation of the crystallites in deformed metals: Representation is by means of "pole figures." In cold-rolled face-centered metals the 111 direction lies in the direction of rolling, and the 011 direction in the cross direction. In iron, body-centered cubic, the direction of rolling and the cross direction are indexed 011, and the (001) plane is parallel to the surface of the foil. The formation of texture by drawing, cylindrical compression, rolling, and plane parallel deformation is analyzed. Warpage of the planes of the crystals is a factor in hardening during cold working. Contains 39 references. JLG(5b)

Alloys of Zinc and Manganese. (Le leghe di zinco e manganese.) N. PARRAVANO & V. MONTORO. *La Metallurgia Italiana*, Vol. 22, Dec. 1930, pages 1043–1051.

X-ray studies on 14 Zn-Mn alloys showed, under 1% Mn, a hexagonal solid solution (η) of Mn in Zn. The saturated η has a lattice constant of 2.67 A. U. and an axial ratio of 1.85. In an alloy of 1.9% Mn, the ε phase was detectable. ε is taken to be $MnZn_7$ (10.73% Mn), it has a hexagonal structure, a lattice constant of 5.634 A. U., and an axial ratio of 1.58. Although ε is considered to be a definite compound, alloys ranging from 8.6 to 11.9% Mn are tabulated as showing only the ε phase, with the same constant and axial ratio. η plus ε appeared between 1.9 and 8.1% Mn. Between 12.2 and 20.7% Mn, η plus γ were present. γ is considered to be $MnZn_3$, body centered cubic, with a lattice constant of 9.195 A. U. The unit cells of the 2 compounds are taken as made up of 16 atoms (2 $MnZn_7$) and 48 atoms (12 $MnZn_3$), respectively. HWG(5b)

Examining Metals by Means of X-Rays. (Metalltechnische Röntgenuntersuchung. Neuere Forschungsergebnisse.) A. HERR. *Giesserei Zeitung*, Vol. 27, Nov. 1, 1930, pages 590–598.

The possibilities of detecting failures in casting by means of X-rays is considered from the standpoint of the recent development. GN(5b)

Constitution of High-purity Aluminum-titanium Alloys. WILLIAM L. FINK, KENT R. VAN HORN & P. M. BUDGE (Aluminum Co. of America). *American Institute Mining & Metallurgical Engineers, Technical Publication* No. 393, 1931, 18 pages.

The liquidus and solidus in the Al rich Al-Ti alloys were determined. The liquidus rises rapidly with the Ti content, beginning at about 0.2% Ti. There is practically no solid solubility of Ti in Al. A compound $TiAl_3$ is formed. A complete X-ray analysis of this compound is given. It is tetragonal with a = 5.45 and c = 8.60 A. U. Contains 9 references. JLG(5b)

Quantitative Analysis by X-Ray Spectroscopy. C. E. EDDY & T. H. LABY. *Proceedings Royal Society*, London, Vol. 127, Series A, Apr. 1, 1930, pages 20–42.

Includes a description of the quantitative analysis of alloys of elements of nearly equal atomic numbers by means of X-rays. The intensities of analogous spectral lines on photographic films were measured photometrically and the percentage compounds of the alloys calculated with an accuracy of about 1 in 200. Cu-Zn, Sn-Cd, Pb-Be and Sn-Zn alloys were investigated and good results obtained except for the Sn-Zn alloys where the atomic numbers differ greatly. Heterogeneity of the alloy when used as the X-ray tube target has very little effect upon the results. (5b)

X-Ray Investigation of Metals in the U. S. S. R. E. F. BACHMETEW. *Metals & Alloys*, Vol. 1, Nov. 1930, pages 828–830.

An X-Ray Study of the A_3 Point of Iron and Some Iron-Nickel Alloys. OSCAR L. ROBERTS & WHEELER P. DAVEY. *Metals & Alloys*, Vol. 1, Aug. 1930, pages 648–654.

The transition temperature at which the body-centered cubic structure of very pure Fe changes to the face-centered cubic structure is found to occur reversibly at a temperature between 907 ± 3° C. and 910 ± 3° C. The Ac_3 points for alloys of Fe and Ni containing 1.04, 2.78, 4.27, 11.73, 13.21% Ni are found to lie between the limits, respectively, 820–815° C., 720–715° C., 660–655° C., 525–520° C., 520–515° C. The Ac_3 and Ar_3 points do not coincide. The fractional lowering of the Ac_3 point is greater for the first 10% Ni than it is for the larger percentages. Spectroscopic analysis of the alloy used is included. Technique of preparation of specimens, apparatus used, and procedure of observations are described in detail. ESC(5b)

Lattice Distortion as a Factor in the Hardening of Metals. W. L. FINK & K. R. VAN HORN. *Engineering*, Vol. 130, Sept. 19, 1930, page 358.

Abstract of paper read before the Institute of Metals, Sept. 1930. See *Metals & Alloys*, Vol. 1, Nov. 1930, page 845. LFM(5b)

X-ray Studies of Gold Copper Alloys. (Röntgenuntersuchungen an der Legierung AuCu.) K. OHSHIMA & G. SACHS. *Mitteilungen der deutschen Materialprüfungsanstalten*, Sonderheft 13, 1930, pages 129–135; *Zeitschrift für Physik*, Vol. 63, July 14, 1930, pages 210–223.

Cu and Au form, at high temperatures, a continuous series of solid solutions. Below 400° the solid solution decomposes, over a wide range of concentrations with the formation of AuCu and $AuCu_3$. AuCu has a tetragonal face centered, and $AuCu_3$ a cubic face centered structure. By quenching from above the transformation temperature, followed by aging, age-hardening heat treatment is possible. This seems to be due to AuCu, not to $AuCu_3$. The behavior in respect to AuCu is somewhat similar to the α-γ inversion in iron. The cubic phase in the alloy corresponding to the composition AuCu has a lattice constant of about 3.86 A. U. The tetragonal phase has the constants a = 3.95 and c = 3.68 A. U., the a:c ratio being 1.072. The change of cubic to tetragonal is shown by the following table:

Treatment	Ratio a:c
Very slowly brought to 500° C. and cooled	1.07_4
Quenched from 600° C.	1.00_4
Quenched and drawn at 200° C. for 1/2 hr.	1.00_8
Quenched and drawn at 200° C. for 2 1/2 hrs.	1.01_7
Quenched and drawn at 200° C. for 7 1/2 hrs.	1.02_4
Quenched and drawn at 250° C. for 1/6 hrs.	1.04_4
Quenched and drawn at 250° C. for 2/3 hr.	1.05_7
Quenched and drawn at 250° C. for 1 2/3 hrs.	1.04_3
Quenched and drawn at 250° C. for 3 2/3 hrs.	1.07_6
Quenched and drawn at 250° C. for 8 2/3 hrs.	1.06_7

X-Ray Examination of Commercial Galvanized Iron by a Modified Reflection Method. CHARLES W. STILLWELL & GEORGE L. CLARK. *Industrial & Engineering Chemistry, Analytical Edition*, Vol. 2, July 15, 1930, pages 266–272.

A modified technic for obtaining diffraction patterns by reflection is described, the method being used particularly for metals and alloys. The composition of the various phases is given for galvanized iron wire, and galvanized Armco sheet steel. A complete description of zinc and other metallic coatings can be obtained only by coöperative microscopic and X-ray analysis, the former to give a picture of the distribution of the several phases, and the latter to determine the state of combination of the metals in these phases. Diffraction patterns are shown. MEH(5b)

PHYSICAL, MECHANICAL & MAGNETIC TESTING (6)

Tensile Forces in Stranded Cables. (Die Dehnungsarbeit an Seilen.) J. GROEBL. *Elektrotechnische Zeitschrift*, Vol. 51, Dec. 4, 1930, pages 1669–1673, 1687, 1713–1716.

It has been observed that stranded cables as used in electrical transmission lines gave way at 50% of their calculated tensile strength and broke at the suspension point where it could be clearly seen that a torsion must have been the cause. The author shows that in such ropes under load, torques are developed in the layers of strands which in the usual construction of a cable do not compensate one another completely but that a differential torque remains which increases proportionally with the load of the cable. These torques cause a torsion in the cable in such a manner that one layer of strands is turned still further in the direction in which it is wound, and the other layer in the opposite direction, is made looser; the former layer is therefore stressed more than normal, the other less. Thereby the proportional elastic limit may easily be exceeded so that fracture results at the place of suspension where the cable is clamped and can not follow the torsion. These conditions are theoretically investigated, the torsion curve derived, and the apparent elastic modulus calculated both for cables clamped on one end and on both sides. Finally, a cable construction is developed from these reasonings in which the torques in the individual layers of strands balance one another. For cables with 3 layers for instance this is done by winding the 2 inner layers in the same direction and the outer layer in the opposite. To obtain absolute equilibrium of the torsional moments the section of the outer strand and its individual wires is, further, reduced so much as to make the torsion in this layer exactly alike and of opposite direction to the torsion of the 2 inner layers. The tests made with a cable built up in this way shows it to be absolutely free of torsion, with an absolutely uniform distribution of load over the whole section. Ha(6)

Vibration Tests on Steam Turbine Nozzles in Order to Determine the Quality of the Riveted Joints between Nozzles and Peripheral Holding Bands. (Schwingungsversuche an Dampfturbinenschaufeln zur zahlenmässiger Bestimmung des Gutegrades der Nietverbindung zwischen Schaufeln und Deckbändern.) G. KIRCHBERG. *Forschung und Technik*, 1930, pages 478–489.

A special test arrangement is described with which the frequencies of vibration of steam turbine nozzles and bundles of nozzles can be determined and compared with calculated values. From the tests, it is concluded that the quality of the joint between nozzles and band is of a constant value and does not depend on the dimensions of the nozzles. The theory of the calculation is given and numerous oscillograms illustrate the process. Ha(6)

Some Results of Fatigue Tests of Metals. A. ONO. *Journal Society Mechanical Engineers*, Tokyo, Vol. 2, Aug. 1929, pages 331–341.

Two different kinds of repeated stress experiments were made; one refers to cast Fe, in which fatigue resistance under repeated tensile stress was compared with that under repeated bending stress. The other experiment refers to fatigue resistance of steel under repeated bending stress applied with or without simultaneous action of steady torsional stress. These experiments show that the stress at a particular point of material cannot be taken as a criterion of strength. The nature of fatigue failure is briefly discussed to elucidate the results of the experiments. (6)

Some Results of Laboratory Tests and of Practical Experience with Rails on Swiss Railways. (Einige Ergebnisse der Laboratoriumsversuche und der Betriebserfahrungen mit Eisenbahnschienen in der Schweiz.) P. LUCCHINI (Swiss Railways) & M. ROS (Materialprüfungsanstalt, Zürich) *First Communications of the New International Association for the Testing of Materials.* Group A. Zurich, 1930, pages 190–212. 24 illustrations.

Wear tests are made on the Amsler machine with 4 cm. diameter discs, 1 cm. wide, upper disc at 200 r. p. m. lower at 180, pressure 40 kg. From the slip between the discs, the pressure, the dimensions of the discs and the total work as shown by the integrator on the Amsler machine, a friction index is calculated. This index multiplied by the pressure and divided by the loss in grams of the specimen for the last 100,000 revolutions is taken as a measure of wear-resistance. The 40 g. pressure used is figured as best representing the pressure between rail and wheel. The speed is slower, but the slip is greater than in rail service. Heat-treated rails of around 300 Brinell show much better wear resistance both in Amsler tests and in the track, than ordinary Swiss rails of 150–205 Brinell. Some heat-treated rails with the surface of the head sorbitic, and some with it martensitic were put in service in 1928. Details of results are promised for the 1931 meeting. HWG(6)

An Account of Investigations on Wear in the Amsler Machine. (Redogörelse för nötningsunders ökingar i Amslermaskin.) C. J. GUNNAR MALMBERG. *Jernkontorets Annaler*, Vol. 114, Nov. 1930, pages 572–592.

The paper gives an account of the investigations which have been carried out on ring material for trolleys and railway coaches in an effort to standardize the tests. The Amsler machine tests wearing resistance by grinding 2 cylinders against each other at pressures up to 200 kg. The cylinders may both be rotated clockwise (positive slippage) or one counterclockwise (negative slippage). In either case the roll moving with the lowest r. p. m. is considered the test piece. Aside from the quality of the material, the amount of wear is shown to be dependent on (1) the total load (2) the local strains, (3) the slippage and (4) the wear distance. It is shown that standardization requires fixation of load (P), diameter (D), r. p. m. (n) and the time (T). In the actual runs, the test cylinders (60 mm. diam.) were turned of wrought iron, while the whetting cylinders (60–55 mm. diam.) were punched from rolled rods which were not heat treated after the rolling. With regard to the diameter of the rolls it was found that there was essentially no influence between 35 and 50 mm., with 10% positive slippage, but the wear was only about 25% as great for 50 mm. as for 35 mm. with 170% negative slippage. Increasing the % C from 0.6% to 0.8% quadrupled the wear but the minimum wear was with 0.90%. The wear also increases with the slippage. Wear on the test cylinder and the whetting cylinder tends to run parallel. The wear decreases with increased Brinell hardness, and the total wear is a minimum when the hardness of the test cylinder exceeds that of the other cylinder. Oil hardened test cylinders wore down the whetting cylinder much more than did water hardened test cylinders. It is felt that the structure plays a large part in wearing resistance. The author concludes that no great difficulty should be encountered in standardizing dimensions of the test piece, load, slippage, r. p. m. and duration of test. (Five references.) HCD(6)

Physical and Chemical Properties of the Light Metals. Mechanical Testing of Aluminum Alloys. A. VON ZEERLEDER (Aluminum Industrie A. G., Switzerland). *First Communications of the New International Association for the Testing of Materials.* Group A. Zurich, 1930, pages 257–272.

Compilation of the properties of Al, Mg and most of their industrially important alloys. Preferred test bar sizes and test methods are shown and commented upon. HWG(6)

Strain Hardening of Lead, Tin, Cadmium and Zinc at Different Temperatures. (Etude sur l'ecrouissage du plomb, de l'etain, du cadmium et du zinc, a differentes temperatures.) ALFRED MOLNAR. *Revue de Metallurgie*, Vol. 27, Oct. 1930, pages 522–534.

Pb, Sn, Cd and Zn were strained 25 and 50% at different temperatures in the range —75° to 200° C. The specimens were then kept at the same temperatures and their hardness was measured at intervals without changing the temperature surrounding them. All these metals are susceptible to strain hardening. The amount of it depends on the temperature of deformation and the temperatures at which specimens are kept after straining. Pb strained and kept at —40° retains its accrued hardness indefinitely. Strained and kept in the range —40° to 50° it gradually loses the acquired hardness, returning to the annealed condition. Above 50°, no hardening takes place because the strains are instantaneously relieved. Sn remains strained at —20° and is instantaneously relieved at 50°. For Cd these figures become respectively —40° and 25°. Zn does not soften under 15° and the instantaneous relief of the strain calls for 300°. These results were confirmed by X-ray study. Tensile testing at different temperatures and using 2 cm./min. and 70 cm./min. loading speeds showed that at faster loading the metals behave as if they were strained. The increase in temperatures reduces the difference between the results obtained by fast and slow pulling until they become the same. This occurs for Pb at 80°, for Sn at 100°, for Cd at 50° and for Zn at 150° at which temperature strains seem to be instantaneously relieved. JDG(6)

Creep Limit under Alternating Tension and Compression. (Der Fliessbeginn bei wechselnder Zug-Druckbeanspruchung.) W. KUNTZE & G. SACHS. *Mitteilungen der deutschen Materialprüfungsanstalten*, Vol. 14, 1930, pages 77–82.

See *Metals & Alloys*, Vol. 2, Feb. 1931, page 36. (6)

Wear Resistance of Dies Studied. *Chemical & Metallurgical Engineering*, Vol. 36, Oct. 1929, page 617.

United States Government is investigating the abrasive action of plastic clay in flowing through dies, in order to determine the relative "wear values" of different metals used for lining dies. The data obtained from 10 tests on cast-iron and 44 on C-Cr steel indicate that the relation between extrusion pressure and abrasion loss of metal is a straight-line function according to the the equation $\frac{PS}{W} = K$, in which P is the extrusion pressure, S, the sp. gr. of the metal, W the loss of the metal in weight, and K, a constant characteristic of the wearing quality of the metal. Value of K for cast-iron as compared to that for C-Cr steel is as 1 to 10.116. MS(6)

Standardization of Methods for Testing the Fatigue Resistance of Metals. (Normalisierung des Prüfverfahrens zur Ermüdung an Metallen.) K. LAUTE (Staatliches Materialprüfungsamt, Berlin-Dahlem). *First Communications of the New International Association for the Testing of Materials.* Group A. Zurich, 1930, pages 111–118.

Brief statement of principles of fatigue testing. Short-cut methods are inaccurate because they do not bring in the work-hardening factor. Up to 6000 cycles per minute, speed of testing is without effect. Very high-speed tests (30,000 per minute) give erroneous results as they do not allow time for strengthening by understressing. Effects of surface finish and of corrosion are discussed. A table showing the effect of grooves 0.003" deep states that various steels, Lautal, Scleron and Electron drop 8 to 28% in endurance limit when grooved, but that drawn commercial copper rod is unaffected. The endurance limit of this material is given as 17,000 lbs./in.² in the table, but shown as 13,000 lbs./in.² in a curve. The endurance limit is not of extreme value for design purposes because in practice one seldom knows the true maximum load. HWG(6)

Fatigue. (Ermüdung.) P. LUDWIK (Technische Hochschule, Vienna). *First Communications of the New International Association for the Testing of Materials.* Group A. Zurich, 1930, pages 119–132. 17 references.

The fatigue limit for annealed electrolytic copper is given as 13,000 lbs./in.² and when grooved 0.008" deep, 10,000 lbs./in.² Ordinary cast iron or high strength cast iron of 35,000 lbs./in.² tensile strength is unaffected by grooves, the endurance limits being respectively 10,000 and 20,000 lbs./in.² Heat-treated duralumin, annealed yellow brass, yellow brass cold-worked 10% and soft 18–8 steel were also not affected by the groove. All other materials tested were injured by the groove. The character of the surface at the base of the notch is of more importance than the depth of the notch. The German structural steel (No. 37) 50,000 lbs./in.² tensile, 27,000 lbs./in.² endurance limit polished, 21,500 lbs./in.² endurance limit notched in the soft state, on quenching in water from 700° C. and aging 2 weeks at room temperature, rose to 79,000, 44,000 and 41,000 lbs./in.² for the 3 values. Single blow notch bar impact tests do not indicate the susceptibility of an alloy to the notch effect in fatigue, nor does the "damping power" of the alloy. Damping is not a constant of the material, but changes with the nature and intensity of the stress, and with the number of stress cycles that have previously been withstood. A table of static and fatigue properties of 25 alloys is given. Ludwik admits that yield point has no direct relationship to endurance limit, but nevertheless inclines toward the formula-endurance limit = 0.3 (yield point + tensile strength) for calculating endurance limit. However, the formula is only good to ±20%, and does not apply at all to age-hardened light alloys. HWG(6)

Constancy of the Work Done to Fracture. (Konstante Brucharbeit als Erklärung für den Bruch durch Ermüdungs- und andere Belastungen.) K. LJUNGBERG (Technische Hochschule, Stockholm). *First Communications of the New International Association for the Testing of Materials.* Group A. Zurich, 1930, pages 149–154.

Data are cited to show that if a tensile test is interrupted and resumed several times, the fracture occurs when the total area of all the hysteresis loops corresponds with the work necessary to cause fracture in un-interrupted loading. This is thought to extend to fatigue fractures as well and to account for the relationship between tensile strength and endurance limit. Three tests on steels are given, but no experiments are reported on non-ferrous metals in which the tensile-endurance relationship does not hold. HWG(6)

A Study of Slip Lines, Strain Lines, and Cracks in Metals under Repeated Stress. H. F. MOORE & T. VER. *University of Illinois Bulletin* No. 209, June 3, 1930, 62 pages; *Metallurgist*, Sept. 1930, pages 141–142.

Study of the mechanism of the fracture of metals under stress and the interrelation and significance of such phenomena as slip lines, strain lines, fatigue cracks and other signs of structural damage to metals. The following materials were studied: Armco Iron; 0.20 Carbon Steel S.A.E. 1020; Chrome-Nickel Steel S.A.E. 3135; Stainless iron (Ascoloy); Brass; Monel metal; Duralumin. Results are tabulated. Profuse micrographic illustrations. VVK(6)

Tensile Strength, an Instability Phenomenon. (Die Zugfestigkeit, eine Labilitätserscheinung.) P. MELCHIOR. *Forschung und Technik*, 1930, pages 533–538.

In carrying out a tensile test, the load is not increased arbitrarily but the elongation, ϵ, is impressed and the resistance, σ, against elongation is observed. The tensile strength has, therefore, no direct relation to the fracture; it is an unstability phenomenon of cylindrical or prismatic test rods. The faster the elongation velocity, μ, the greater the resistance, σ. These 3 variables, ϵ, σ and μ, are used as a means for correlating the results of tensile tests with the results of endurance tests. It follows that (1) tensile test and endurance test are tests of an entirely different nature which must not be confused with each other; (2) the results of tensile tests with definite elongation velocity permit the recognition of laws of endurance strength; (3) the results of endurance tests can be supplemented by tensile tests under simultaneous observation of the elongation velocity. Ha(6)

Magnetic Testing of Non-Uniform Material. (Prüfung ungleichmässigen Werkstoffes auf magnetischem Wege.) W. S. MESSKIN. *Archiv für Eisenhüttenwesen*, Vol. 4, Oct. 1930, pages 215–220; *Stahl und Eisen*, Vol. 50, Dec. 11, 1930, page 1751.

The author describes a new method to determine the magnetic properties of non-uniform material, i. e., material, the core of which has other magnetic characteristics than the skin. Exact determinations of the normal induction curve show that it is really composed of 2 branches provided the material is non-uniform. From these curves, the maximum permeability can be found by a simple geometric procedure and the coercive forces can then be determined by certain approximate calculations. The approximate formulae are given as well as the theoretical principles of this new method. GN(6)

Dynamic Properties of Magnesium Alloys. (Proprietà dinamiche delle leghe ultra leggere.) I. MUSATTI. *La Metallurgia Italiana*, Vol. 22, Dec. 1930, pages 1052–1068.

Rotary beam endurance tests on a McAdam type tapered cantilever bar were made on a group of magnesium alloys and compared with duralumin. Tests were carried to 60 million cycles. If the S-N curve was flattening out, it was extrapolated to 100 million and the corresponding stress taken as the engineering endurance limit. If it was not, extrapolation was made to 1 billion cycles. After running 60 million at a stress a little below that taken as the endurance limit, specimens of alloys A, E, Fh and If were run at higher stresses, and showed material strengthening by understressing, thus affording evidence that the magnesium alloys probably have a true endurance limit. Care was taken to avoid corrosion during storage and in the endurance tests, by oiling the specimens. The extruded 4% Cu alloy of Mg was very poor in endurance and repeated impact. That with 4% Zn was nearly as good as those with 6½ to 10% Al, plus a little Mn, in endurance, but not quite so good in repeated impact. The Al-Mn alloys of Mg were slightly superior to heat-treated duralumin in endurance, but not as good on repeated impact. The repeated impact tests were made on an Amsler machine using a 1 mm. deep, 5 mm. wide, 3.63 mm. radius round notch. With log plotting of energy of blow against number of blows to fracture, the plots were straight lines in most cases, down to 2 kg. cm., the smallest energy used, no sign of a repeated impact endurance limit being evident. In alloys F, Fh, Fw and D (all alloys with Al), the plots were somewhat curved, below 3 kgcm., as was the case with duralumin. Single blow notched bar impact tests, made in a 15 kg. m. Amsler machine on 10 × 10 mm. Charpy bars with a 2 mm. deep, 2 mm. wide Mesnager notch of 1 mm. radius, were carried out over a range of temperatures from —50° to +50° C. In the extruded materials, those with the smaller amounts of alloying elements, i. e., those weaker in tension, were generally superior in single blow impact. All, however, were relatively weak. Alloy G was a trifle weaker at +50° C. than at room temperatures; all the others were better. All the Mg alloys were the more brittle the more the temperature was dropped below room temperature, though the very brittle cast Mg alloys showed but a slight drop. On the other hand, the heat-treated duralumin showed marked improvement in impact resistance at temperatures below 0° C., and a slight decrease at +50° C. The curves for duralumin and for Mg alloys have opposite trends. The angle through which the Charpy bar had bent before fracture was measured after fitting the broken halves together. Duralumin showed a larger angle at —50° than at +50° C. while the reverse was found for the Mg alloys. On the whole the extruded alloys of Mg with Al, plus a little Mn appeared somewhat superior to those alloyed with Zn, and very much superior to those with Cu. The static properties and the repeated impact properties of 2 cast Mg alloys containing Al and Zn were compared with those of cast silumin (Al with 12½% Si). The silumin rotary beam endurance bars were so full of flaws that no good endurance tests could be made. Fatigue data on cast silumin by Wagner would indicate it to be decidedly inferior to the cast Mg alloys. The data are collected in the following table:

Methods Employed in the Mechanical Testing of Aero Steel Strip. E. SKERRY. *Aeroplane*, London, Vol. 38, Feb. 26, 1930, pages 352–353.

The method of testing steel strip which commends itself, is the one that gives accurate readings quickly without use of elaborate apparatus. The provision of a suitable test piece, the selection of extensometer, and the elimination of the personal element in the bend test are necessary. (6)

Tensile and Impact Tests at Low Temperatures. (Zerreiss- und Schlagversuche bei tiefen Temperaturen.) P. SCHOENMAKER (N. V. W. Smit & Co., Holland). *First Communications of the New International Association for the Testing of Materials*. Group A. Zurich, 1930, pages 237–250.

Tests from room temperature to —80° C. on 5 carbon steels of 0.14 to 1.75% C. on a 25% Ni steel, on 60:40 and 70:30 brass, copper and zinc. All become stronger in tension as the temperature decreases (zinc was not tested). Hypoeutectoid steels decrease in impact resistance. The hypoeutectoid steels and Zn, all with low impact strength, retain their impact values without much change. The brasses and copper show somewhat improved impact resistance at the lower temperatures. Impact values are not given on the 25% Ni steel. HWG(6)

Effect of Metallic Coating upon Fatigue. R. H. D. BARKLIE & H. J. DAVIES. *Engineer*, Vol. 150, Dec. 19, 1930, pages 670–673.

Selected for publication in the Proceedings of the Institution of Mechanical Engineers. Tensile stress in Ni, electro-deposited on a steel test piece which is subjected to a fatigue test, acts like a mean stress and seriously reduces the fatigue limit. This reduction is greater than that produced by a circular nick of depth equal to the thickness of the Ni deposit. Electro-deposits of Ni having little internal stress have a greatly reduced influence on the fatigue range of the steel and the conditions for the electro-deposition of nearly stress-free Ni are described. Electro-deposits of stress-free Cu reduce the fatigue limit of steel. Electro-deposits of Zn having a slight internal stress causing them to expand do not lower the fatigue limit of steel. Electro-deposits of Pb are practically without influence. Intermediate Pb films between stressed Ni and steel have been found to insulate the steel core from the effects of the Ni. LFM(6)

The Endurance Strength of Non-Welded and Welded Cast and Rolled Materials. (Die Dauerfestigkeit ungeschweisster und geschweisster Guss- und Walzwerkstoffe.) B. BARTELS. *Giesserei Zeitung*, Vol. 27, Nov. 15, 1930, pages 607–616; Dec. 1, 1930, pages 637–645; Dec. 15, 1930, pages 661–669.

The endurance strength of the main construction materials was tested in the welded and non-welded state. Lehr's short time method was found to be applicable also to welded materials. The endurance strength of cast Fe essentially depends on the shape of the graphite present. Lamellar graphite close to the surface of the specimens may bring about a notch effect, impairing the endurance strength. Surface injuries due to machining did not decrease the strength of cast Fe. Polishing does not bring about an improvement. Graphite in eutectic arrangement in a pearlitic matrix increases the endurance strength about 3 times above the normal values. The endurance strength of welded cast Fe is generally somewhat lower than that of non-welded Fe. The tensile strength of welded cast Fe decreases more than the endurance strength. Steel, copper and silumin were also tested. GN(6)

Electroplating (7a)

Some Experiments on the Electro-Deposition of Gold from Alkaline Cyanide Solutions. E. T. DUNSTAN. *Journal Chemical Metallurgical & Mining Society of South Africa*, Vol. 31, pages 118–127 (1930).

No evidence of regeneration of cyanide by electrolysis of a working cyanide solution was found, in fact, a further loss occurred. The use of a rotating cathode does not materially increase the current efficiency, which is extremely low, due to the dilute solutions employed. Electrolytic methods cannot economically improve upon zinc precipitation. It is doubtful if space and power would be saved, as the solution required four passes through the cell. The rotating cathode has a depolarizing effect, probably due to the friction of the solution keeping the surface free from bubbles of gas, which enables a lower voltage and higher current density to be employed. AHE(7a)

Measurements of Hydrogen Ion Concentration in Plating Baths. R. E. BREWER & G. H. MONTILLON. *Transactions American Electrochemical Society*, Vol. 55, 1929, pages 357–382.

Includes discussion. Discusses the theory of the hydrogen, oxygen, quinhydrone, antimony and lead oxide electrodes for the determination of pH in acid plating baths. The limitations of the various electrodes in typical nickel, cobalt, iron, zinc and chromium plating solutions are indicated and the results are given of a comparative study of the electrometric and colorimetric methods of measuring hydrogen ion concentration. The oxygen electrode is found to give good results in nickel and cobalt baths and to be useful in checking other methods of measurement. For general usefulness, as well as ease of measurement, the quinhydrone electrode is recommended. (7a)

Improvement in Electroplating Quality Needed to Meet Competition. E. B. NEIL. *Automotive Industries*, Vol. 63, Oct. 18, 1930, pages 560–564.

The article discusses in detail the quality of plating on present-day vehicles, nickel plating, heat treating of chromium plate, durability tests, control methods, chromium plating for resistance to abrasion, electrodeposition of iron and future prospective progress in electroplating. GN(7a)

Proposed Chromium Plating Regulations. *Metal Industry*, N. Y., Vol. 28, Sept. 1930, pages 431–432.

Summarizes regulations put forward by British Governmental Dept. to reduce the health hazard in Cr plating to a minimum. Results of investigation showed that of 223 persons examined about 43% had dermatitis, while nasal changes were observed in about 52%. Caused by spray due to evolution of gases. May only be eliminated by efficient exhaust ventilation. VSP(7a)

Chemicals Used in Electroplating and Metal Finishing. *American Machinist*, Vol. 73, Dec. 11, 1930, page 937.

List of chemicals, chemical formula, common name, color, form, grades and size of standard containers. RHP(7a)

Chromium Plating. *Electrical Review*, Vol. 107, Nov. 28, 1930, pages 930–931.

Extracts from the proceedings of the Electroplaters' and Depositors' Technical Society. Consists of a discussion of the proposed British Home Office regulations for safe-guarding the health of workers, and of an abstract of a paper by J. W. Cuthbertson on practical difficulties in electrodeposition. MS(7a)

Plating of Electrical Appliances. *Metal Cleaning & Finishing*, Vol. 2, March 1930, pages 229–231.

Describes procedure and gives solution formulae of the Westinghouse Electric and Manufacturing Company's plant at Mansfield, Ohio, for Cr and Cd plating of electric iron parts, reflectors and miscellaneous appliances. MS(7a)

Electrodeposition of Chromium for Engineering Service. *Metal Cleaning & Finishing*, Vol. 2, Feb. 1930, pages 131–136.

Describes the practice of the U. S. Chromium Corporation, Wilkinsburg, Pa. for producing a hard wear resistant surface on steel rolls, dies, etc., and for producing lustrous surfaces. Includes solution formulae. MS(7a)

Electroplating Aluminum. *American Metal Market*, Vol. 37, Dec. 26, 1930, pages 4, 10.

A reprint from a booklet issued by the Aluminum Co. of America. The best plating procedure for different types of Al alloys is discussed in sections covering alkaline cleaning, acid cleaning, plating on a smooth surface (Cr, and Zn "Flashing"). Ni plating of Al is desirable but requires "roughening." For roughening commercially pure Al (2 S) an etching solution contains: nickel chloride 36 oz., hydrochloric acid 0.2 gal., water 1 gal. Operation is conducted at 90° F. The roughening of alloys of the 2 S and Strong Alloys group is accomplished in a dip containing: hydrochloric acid 1/3 gal., water 2/3 gal. and manganous sulphate 1/2 oz. The temperature is 90° F. For castings, the dip contains: nitric acid 3 parts, hydrofluoric acid (48–52%) 1 part, temperature 75–80° F. Heavy Cr deposits (.001") may be applied directly to the castings after the Al surface has been roughened by this dip. WHB(7a)

Practical Handbook on Electro-Plating. W. Canning & Co., Birmingham, 1928. Cloth, 6 × 9 1/2 inches, 298 pages.

This little book is a very convenient and helpful treatise for the practical electroplater and metal worker. The compilers and publishers have been supplying the British electroplating industry with high-grade standard equipment, plating solutions and accessories for many years. The text, therefore, is based on a very wide range of experience and the various procedures recommended are authoritative.

The first section of the book (60 pages) covers "Grinding and Polishing;" the second, "Cleaning and Dipping" (20 pages); the third and main section, "Electro-Plating" (50 pages); and the last, "Bronzing, Lacquering and Enamelling" (44 pages).

Although the only apparatus, equipment and salts cited or recommended are "Canning," and little or no reference is made to other sources, nevertheless, the little book is full of useful information for the commercial electroplater. Numerous illustrations add greatly to the value of the book.—Colin G. Fink (7a)-B-

Electrometallurgy (7b)

Another Porphyry Copper in the Making. GEORGE J. YOUNG. *Engineering & Mining Journal*, Vol. 130, Nov. 24, 1930, pages 522–524.

The development of the Bagdad Copper property near Hillside, Arizona, its prospects and reserves and details of pilot-plant construction and operation are briefly outlined. A flowsheet of the concentrating mill and the experimental hydrometallurgical plant are shown. WHB(7b)

Principles of Calculating for Electrolytic Copper Refining Plants. (Grundlagen zur Berechnung von Electrolytischen Kupferraffinationsanlagen.) FRIEDRICH VOGEL. *Metall & Erz*, Vol. 27, March 1930, pages 150–155.

In laying out an electrolytic Cu refining plant, many factors must be considered such as daily output, quantities of raw material available, composition of raw material, type of solution to be used, availability and cost of electric current, size of units and electrodes, current density. Statistics are given for the plants at Raritan, Great Falls and El Paso. CEM(7b)

INDUSTRIAL USES & APPLICATIONS (9)

Bimetal—Its Function and Application. W. J. P. ROHN. Part 1, *Metallurgia*, Vol. 3, Nov. 1930, pages 17–19, 25; Part 2, Dec. 1930, pages 59–61.

Bimetal strips are used for temperature measurement or temperature control. They are made by soldering, welding or riveting 2 strips of dissimilar metals. Ni-Fe alloys are usually used for the strip having the low coefficient of expansion. Cu, Al, Fe-Ni alloys and various other materials can be used for the other strips but the materials used should have a high elastic limit. Cu and Al are not very satisfactory. Bimetals made from dissimilar Fe-Ni alloys are the most satisfactory. The addition of 5% Mo to these alloys makes them less susceptible to variations in heat treatment. Curves are given showing the coefficients of expansion of various metals and alloys at different temperatures and the deflections of several bimetal strips over a range of temperatures. Part 2 gives effect of dimensions on action of bimetal strips. In order to obtain the greatest deflections the strips should be as thin as possible, but the force exerted by the free end is proportional to the third power of the thickness. Describes equipment for testing strips. The strips should be cold rolled and heat treated to obtain the maximum strength and elasticity. The 2 parts should be firmly attached to each other. Bimetal strips are capable of yielding high precision results. See *Metals & Alloys*, Vol. 1, Jan. 1930, page 342. JLG(9)

Ferrous Metals Used in Airplane Construction. J. B. JOHNSON. *Proceedings American Society for Testing Materials*. Vol. 30, Pt. 2, 1930, pages 28–33.

Discussion appended. See *Metals & Alloys*, Vol. 1, Nov. 1930, page 849. (9)

The Place of Iron Casting in Industry. *Engineering*, Vol. 128, Dec. 13, 1929, pages 776–777.

Comments on advances which have been made in recent years in improvement of cast-iron. British Cast Iron Research Association has done much toward developing little known properties of cast-iron. Heat-resisting properties of cast-iron have been studied. At the Engineering Experiment Station of the University of Illinois, work is being done on the relation between fatigue strength and other mechanical properties. Professor Hanson of the University of Birmingham is making a study of the whole subject of cast-irons. The fact that the British Engineering Standards Association now has a specification for cast-iron shows that progress is being made. LFM(9)

Solid Nickel and an Industrial Revolution. P. E. NORWOOD. *Australian Manufacturer*, May 4, 1929, pages 19 and 41.

Popular account of the applications of nickel and Monel Metal in the dairy, textile dyeing and other chemical and semi-chemical industries. (9)

Insulated Aluminum Wires and Cables. *Electrical Railway Journal*, Vol. 75, Jan. 1931, pages 51–52.

Under the trade name Electral, insulated aluminum-wires and cables have been announced by the General Cable Corp. The initial group of insulated aluminum conductors includes net work cable, non-metallic underground cable, insulated line wire, tree wire, armored cables, magnet wire, starter cable and car wiring cable. Connections will be made by applying high pressures to sleeves by means of a specially designed lightweight hydraulic press. Where tensile strength is not of prime consideration, conductors of Electral wires and cables are all aluminum. WHB(9)

How Germany Has Successfully Developed the Welded Ship. *Iron Age*, Vol. 126, Aug. 21, 1930, pages 481–484.

Comparison of weight and cost of welded and riveted ships showed the welded vessels weighed less but the cost was slightly greater. North German Lloyd specifications used for short cruising coastal vessels. Material must be carefully laid out. Each seam should be completely welded before beginning the next. Special attention paid to preparation of seams joining thick plates with thin ones. Lengthwise seam in tank compartment does not constitute an element of danger. VSP(9)

Notably Light Airplane Wings of Alloy Steel Heat Treated. *Iron Age*, Vol. 126, Aug. 21, 1930, page 485.

Steel wing beams comparing in lightness and strength with Al alloys are manufactured by the Metlab Metallurgical Laboratories, Inc., Philadelphia. Beams are of Warren truss type of Cr-Mo steel tubing No. 4130X with an analysis of 0.25 to 0.35% C, 0.40 to 0.60% Mn, 0.04% maximum P, 0.045% maximum S, 0.80 to 1.10% Cr and 0.15 to 0.25% Mo. Cr-Mo tubing is heat treated to tensile strength of 150,000 lbs./in.^{2} Heat treatment is done in a vertical electric furnace and quenched in oil from 1600° F. Weight of each beam is 43 lb. and length is 21 ft. 6 in. VSP(9)

Use of Rustless Steel in the Automobile Industry. *Metal Cleaning & Finishing*, Vol. 3, March 1930, pages 204, 210.

Ford Motor Co. has adopted rustless steel for exposed metal parts, after subjecting the alloy to many severe tests. Samples were tested by the salt-spray method for 400 hrs. without showing any visible attack. A sheet of the metal placed in highly corrosive mine water and removed after 6 months' total immersion, showed no loss in weight. MS(9)

Pearlitic Manganese Steel for Rails. (Perlitischer Manganstahl als Schienenbaustoff.) A. POHL. *Stahl und Eisen*, Vol. 50, Nov. 6, 1930, pages 1574–1580.

The article gives the results of physical tests and practical tests of Mn rails made either in the electric furnace or the open-hearth furnace. It is shown that the pearlitic Mn steel (C: 0.55–0.72; Si: 0.16–0.27; Mn: 1.62–1.89) possesses a high yield point and a high tensile strength, favorable capacity of deformation and high wear resistance. The economic application of Mn steels is discussed. GN(9)

Copper and Its Alloys in Motors and Aircraft. L. S. REID. *Aviation Engineer*, Vol. 3, May 1930, pages 20–22.

Specifications, chemical composition and physical properties of Cu alloys used for seamless tubing, wrought pieces and castings are given. Graphs show Cu-Zn constitution diagram comprising alloys of Cu. (9)

The Replacement of Castings by Weldings. P. L. ROBERTS. *Welding Journal*, Vol. 27, Oct. 1930, pages 297–302; discussion in Nov. 1930, pages 326–328, 342.

Paper read before the Institution of Welding Engineers, Oct. 1930. The advantages of weldings over castings are first presented; strength, lightness, economy. Concrete examples of the replacement of castings by weldings are given and the possibility of a wider field emphasized. Current practice in the construction of a few specific weldings is given. Steam condensers, alternator yokes, bedplates and the like constitute the work with which the author had to deal and he discusses the merits of the welding in these instances. AWM(9)

Comparisons Between Welded and Riveted Joints. (Comparison entre l'Assemblage rivé et soudé.) D. ROSENTHAL (Testing Laboratory, University of Brussels). *First Communications of the New International Association for the Testing of Materials*. Group A. Zurich, 1930, pages 163–167.

Properly welded joints are preferred to riveted ones. (9)

Applications of Stampings, Forgings & Castings in Aircraft Construction. H. G. RUNDE. *Proceedings American Society for Testing Materials*, Vol. 30, Pt. 2, 1930, pages 77–87.

Discussion appended. See *Metals & Alloys*, Vol. 1, Nov. 1930, page 849. (9)

Corrosion of Copper and High Copper Bearing Alloys by Salt Solutions with Particular Reference to the Conditions Prevailing in Potassium Salt Industry. (Ueber die Korrosion von Kupfer und hochkupferhaltigen Legierungen durch Salzlösungen unter besonderer Berücksichtigung der Verhältnisse in der Kaliindustrie.) A. RAUCH & H. KOLB. *Korrosion und Metallschutz*, Vol. 6, June 1930, pages 127–132; July 1930, pages 151–156; Aug. 1930, pages 174–178; Sept. 1930, pages 193–200. 43 references.

A problem of commercial significance precipitated the present investigation: the corrosion attack of chlorides and sulphates of K, Na and Mg in preheater tubes of Cu and Cu-bearing alloys in potassium salt industry. Experiments were carried out partly in the laboratory and partly on a quasi-commercial scale. Determinations of corrosion attack were performed by Cu analyses of the corroding medium. The following factors were studied: influence of concentration, temperature, time, O content of the electrolyte, aqueous solutions, corrosion attack by solid salts. The material investigated consisted of various grades of copper, brass and bronze. The superiority of Cu-alloys (except tin-bronzes) in comparison with brands of Cu was established. Additions of Al materially improve the corrosion resistance. The local dezincification of brass is pointed out. The surface conditions of the material tested is considered and potential measurements are carried out. Experiments with Tödt's Korrosimeter did not turn out satisfactorily. In conclusion, the authors report on experiments on a large scale which in general confirmed the laboratory tests showing the most favorable behavior on the side of the Al-bronze. EF(9)

Hardened Rails. (Gehärtete Schienen.) W. OERTEL. *Stahl und Eisen*, Vol. 50, Nov. 6, 1930, pages 1584–1585.

The article briefly discusses the 3 most important methods for the improvement of rails by surface hardening, the Sandberg method, the method Neuves-Maisons and the Maxhütte method. The method of the Maxhütte seems to give the best results and seems, therefore, to be most adaptable for practice. GN(9)

The Development and Use of Alloy-Steel Castings in Modern Industry. H. D. PHILLIPS. *Pit & Quarry*, Vol. 20, June 18, 1930, pages 54–56.

A discussion of the properties imparted by Cr and Mo and the manufacture of castings. (9)

Iron and Steel Used in a Modern Brass and Copper Mill. H. G. KESHIAN. *Iron Age*, Vol. 126, Nov. 6, 1930, pages 1282–1286, 1359–1360.

Brass and Cu mills have always used Fe and steel in construction of their equipment. In melting brass and Cu low-C-high-Cr iron is used for stirring molten metal. For mold material gray Fe ingot molds are employed. For scalping, overhauling and milling cast and rolled bars and ingots, high-speed steel is preferred. Use of steel rolls for breaking down and finishing operations is steadily gaining ground. No standard type of steel as to chemical composition is to be found for cold shearing of sheets. Heat treated alloy steel chains made of either Cr-Ni, Cr-V or pearlitic Mn steels are proving superior to medium C steel chains for cold drawing equipment. Steel to cold draw brass and Cu must have maximum wearing properties without tendency to scratch the work. Steels for drawing dies generally have from 1.25% to 1.35% C, 4% to 5% W, or 2% C and 5% Cr, or 2% C and 12% Cr. In hot working brass and Cu types of steels used are not expected to fill a stricter demand than for hot working Fe and steel. Hot working steels are classified as follows: (1) these contain C and Cr; (2) C, Cr and W; (3) C, Cr, W and V; (4) C, Cr, W, V and Ni; (5) C, Cr and Mo. In fabrication of various articles from brass and Cu, kind of steel is not different from steel used on similar operation in fabricating iron and steel articles. VSP(9)

Building Contractors Favor Steel Equipment. *Steel*, Vol. 87, July 17, 1930, pages 48, 50.

Sidewalk bridges, material towers and scaffolding made of steel are replacing wooden structures. MS(9)

Manganese Steel is Employed in Kill van Kull Bridge. *Steel*, Vol. 87, July 17, 1930, pages 57, 60.

Lower cord of the bridge is fabricated from Mn steel rolled plates and shapes with Mn steel rivets. Composition of the steel is 0.40% maximum C, 1.80% Mn, 0.04% P, 0.05% S and 0.10–0.30% Si. Physical properties are: ultimate strength, 9000 lbs./in.^{2}; yield-point, 55,000 lbs./in.^{2}; elongation, 16%; and reduction of area, 30%. Rivets were slightly softer than the rolled shapes and had an ultimate strength of 82,000 lbs./in.^{2} and a yield point of 47,000 lbs./in.^{2} Cost of steel is 0.75 cents/lb. less than the price stipulated for Ni steel. Si steel has been specified for cross-pieces and C steel for the approaches and for some of the arch members. Some heavy C steel forgings were used in the construction of the shoe. MS(9)

Nickel Coinage. *Canadian Mining Journal*, Vol. 52, Jan. 9, 1931, pages 44–45, 55.

From "The Nickel Bulletin" (Mond Nickel Co.). A large potential market for nickel as coins remains, particularly in the British Empire. WHB(9)

Fabrication of Metal Furniture. *Metal Stampings*, Vol. 3, June 1930, pages 559–562.

Describes some of the applications of sheet steel and seamless tubing to procedures. Welding is used for assembling. MS(9)

Improved Metals Affect All Products. *Product Engineering*, Vol. 1, Sept. 1930, pages 421–423, 433.

Brief discussions on metal applications by the editors of *Chemical & Metallurgical Engineering, Aviation, Bus Transportation, Engineering News-Records, Power, and Electric Railway Journal.* (9)

Use of Light Metals in Mines. (Verwendung von Leichtmetall im Bergbau.) E. LOHRKE. *Metall und Erz*, Vol. 27, Oct. 1930, pages 521–524.

On account of the limited space in mines and the necessity of using many manually operated tools and devices, the use of light metals is desirable. Their application for ventilators, water pumps, lamps, boring tools, air compressors and mine transportation is described. CEM(9)

Use of Alloy Steels in Iron and Steel Mill Equipment. E. R. JOHNSON & O. BAMBERGER. *Transactions American Society Mechanical Engineers*, Vol. 52, Jan.-Apr. 1930, pages 5–8, discussion pages 8–9.

Substituting alloy steels for the ordinary C steels in its mill equipment is the practice of the Central Alloy Steel Corporation when occasion arises to make a change. Elimination of breakdowns and costly repairs is claimed to be furthered by certain uses of the alloys. A gradual building up of the alloy-steel equipment is taking place. In producing alloy steel itself, the initial cost is low. There are 3 requirements which permit the substitution of alloy steels: (1) Increase of the physical properties of strength, ductility and toughness; (2) The ability to withstand wear and abrasion; (3) Resistance to corrosion. Includes discussion. See also *Metals & Alloys*, Vol. 1, May 1930, page 525. (9)

Copper Steel for Dynamo and Transformer Sheets. A. KUSSMAN & B. SCHARNOW. *Metallurgist*, Sept. 1930, pages 142–143.

See *Metals & Alloys*, Vol. 1, Dec. 1930, page 912. VVK(9)

Plate-Type Residence Floors Offer Market for Steel. LEE H. MILLER (American Institute of Steel Construction). *Steel*, Vol. 87, July 3, 1930, pages 54, 66.

Chromium Plated Molds. H. E. STOCKFISCH (Westinghouse Electric & Manufacturing Co.). *American Machinist*, Vol. 73, Oct. 2, 1930, pages 553–555.

Resistance to wear is the principal justification and value of chromium plating in molds. In glass molds, for both blown and pressed objects, the combination of long wear, preservation of polished surface, elimination of lubricants, and ease of stripping, makes chromium plate an ideal material. Molten glass at 2,100° F does not reduce the adhesion of the plating. Plate should be 0.004 in. thick for good wear. Gives composition of some chromium plated molds which have been used successfully. Discusses hardness methods of replating when the first coat wears through. Old plating should be removed before a new coat is applied. Initial cost of chromium plating is high but it soon pays for itself. RHP(9)

An All-Metal Apartment House. *Iron Age*, Vol. 126, Aug. 14, 1930, pages 430–431.

Describes metal building designed by Bowman Brothers, Inc., Chicago. The frame work is to be of fabricated structural members. The walls will be insulated and the floor of battledeck type. Analysis of 3 types of metal wall was made. These are: (1) Sheet Al with Al framework; (2) Sheet Al with steel framework; and (3) Allegheny Metal, KA2, sheets to be clamped to the framework with straps. The building is to be fabricated almost entirely in shops. VSP(9)

Laundry Machinery Fabricated by Arc Welding. MAURICE TAYLOR (Lincoln Electric Co.). *Product Engineering*, Vol. 1, Sept. 1930, page 405.

Brief article mentioning saving due to replacing cast iron parts with welded steel parts. (9)

Structural & Engineering Light Alloys for Aircraft. R. L. TEMPLIN, F. V. HARTMAN & E. C. HARTMANN. *Proceedings American Society for Testing Materials*, Vol. 30, Pt. 2, 1930, pages 34–40.

Discussion appended. See *Metals & Alloys*, Vol. 1, Nov. 1930, page 849. (9)

Some Unusual Pressed Steel Conversion Jobs. H. W. TINKER (Federal Pressed Steel Co.). *Metal Stampings*, Vol. 3, Jan. 1930, pages 13–16.

Deals with the design and manufacture of tire covers, bumpers, and brake drums. MS(9)

Report of the Technical Director. U. S. Government Printing Office. B. L. WEHMHOFF. *Appendix to Annual Report of the Public Printer for 1930*, pages 105–115. *U. S. Govt. Printing Office*, 1931.

Net dross losses, after recovery of metal from original dross, on remelting about 5½ million lbs. of linotype and 2½ million lbs. of monotype metals at the Government Printing Office in the last fiscal year were 0.48% and 1.74% respectively. The recovery of metal from the original dross was 46% and 47½% respectively. Changes in analysis were as follows:

	Linotype		Monotype	
	Standard for Metal in Use	Metal Recovered From Dross	Standard for Metal in Use	Metal Recovered From Dross
Sn%	4.0 to 4.5	3.55	7.3	5.22
Sb%	11.5	11.80	16.8	14.80
Cu%	0.05(*a*)	0.09	0.4(*b*)	0.14
Pb%	Balance	84.56	Balance	79.84

(*a*) average actual Cu 0.08%

(*b*) average actual Cu 0.15 to 0.18%

Difficulty was met in using stereotype metal of 8% Sn, 15.5% Sb, balance Pb in a 5 ton electrically heated pot, since Sb separated when the pot stood overnight, the top layer containing some 35% Sb. A new alloy of 6½–7% Sn, 12¾–13% Sb, balance Pb casts well at 600° F., pumps well, and the type is hard and tough enough to give 70,000 impressions on news print paper. With tin at 8%, a casting temperature of 650° F. was required. With Sb above 13%, the required temperatures were too high, and the tendency toward separation too great. The wear on type is chiefly due to battering through the first few thousand impressions. Wear during the first 10,000 is greater than between 35,000 and 70,000. Experiments are being run on the use of Bi in stereotype metal. A stirring device consisting of a cage that contains blocks of green wood and can be lowered to the bottom of the pot has been found of advantage in securing better mixing of metal. Work on electrotyping indicates that by use of addition agents, the present current density in Cu electrotyping, 70–80 amps./ft.^{2} can be raised to 150 amps. and still produce good shells. Work is under way on Ni baths. A study is being made of Zn plates for line cuts in photo engraving. HWG(9)

Locomotive Equipped with Roller Bearings. A. K. WEST (Timken Roller Bearing Co.). *Blast Furnace & Steel Plant*, Vol. 18, July 1930, pages 1147–1148.

Hardened and ground Ni-Mo steel, cast Ni steel, heat-treated Ni-V steel and normalized 2¾% Ni steel have been used for various parts and bearing mountings. MS(9)

Steel Ties versus Wood Ties. (Eisen- oder Holzschwelle.) R. VOGEL. *Stahl und Eisen*, Vol. 50, May 22, 1930, pages 721–729.

Experience of the German Federal Railway System indicates that steel ties are superior to wooden ties as regards maintenance of gage, resistance to lateral displacement, lessening of noise and increase in economy. GN(9)

Drop-Forge Metal Propeller. FRANK W. CALDWELL (Hamilton Standard Propeller Co.). *Heat Treating & Forging*, Vol. 16, Aug. 1930, pages 1000–1003.

Paper read before the Pittsburgh Aeronautical Meeting of the American Society of Mechanical Engineers. MS(9)

"Caro" Bronze as a Bearing Metal in the Automobile Industry. (Die Carobronze als Lagermetall in der Automobilindustrie.) A. D. SCHULZ. *Metallwirtschaft*, Vol. 9, Nov. 21, 1930, pages 969–970.

Caro bronze consists of 92% Cu, 8% Sn, ¼% P. It is made entirely from virgin metals, cast into ingots and cold drawn into tubes of the proper diameter for bearings. The author claims that it has better bearing qualities than any other known metal. The high tensile strength of Caro bronze enables its substitution for roller and ball bearings with consequent savings in material, weight and cost. Other advantages are noiselessness and high precision in workmanship. Four examples of the application of Caro bronze as bearings for automobile parts are described in detail. CEM(9)

Malleable Iron Castings in Automotive Design. H. A. SCHWARTZ *Product Engineering*, Vol. 1, Sept. 1930, pages 410–411.

Brief discussion of application of malleable castings in automotive construction. (9)

Comparing Experiments with Pistons of Light-Metal-Alloys. (Vergleichende Versuche über Leichtmetall-Kolbenlegierungen.) M. v SCHWARZ. *Zeitschrift für Metallkunde*, Vol. 22, Dec. 1930, pages 417–420.

The paper, which was presented before the Deutsche Gesellschaft für Metallkunde, Sept. 1929, discusses the efforts to produce high-quality pistons of light metals and is especially concerned with the devices which must be applied in designing and manufacturing the pistons. Chemical composition and physical properties of the most important alloys are listed. A testing machine is described which was designed by the author with the object of investigating the wearing properties of bearing metals and which can also be suitably used for testing the serviceability of light metal pistons. The paper includes 6 illustrations and a discussion. EF(9)

HEAT TREATMENT (10)

Mower Blade Steel Selected and Treated Carefully. H. R. SIMONDS. *Iron Trade Review*, Vol. 86, May 29, 1930, pages 41–43.

Describes practice of the Coldwell Lawn Mower Co., Newburgh, N. Y. Hot-rolled strip steel containing 0.46% C and 0.80% Mn, is used for the blades which are heat treated and formed in one operation. MS(10)

Analysis of Electric Heat Treating of High-Grade Axes. WIRT S. SCOTT (Westinghouse Electric & Mfg. Co.). *Electric Journal*, Vol. 27, Sept. 1930, pages 511–514.

A comparison of results at the plant of the Warren Axe & Tool Co. before and after the change from gas to electric furnaces for the hardening and tempering of axes shows the advantages gained from the use of the electric furnace. See *Metals & Alloys*, Vol. 1, Mar. 1930, page 428. WHB(10)

Devices for Making Locomotive Springs. JOSEPH C. COYLE. *Heat Treating & Forging*, Vol. 16, Aug. 1930, pages 998–999.

In the Denver shops of the D. & R. G. W. Railroad, leaves are formed at 1600–1650° F., allowed to cool to a black heat, re-heated to a refining temperature of 1450–1500° F., quenched in oil, and drawn to 650° or 750° F. in a salt bath. A series of normalizing cooling racks enables the leaves to cool without warping. The salt bath is attached to the high heat furnace and is heated by the waste heat from it. Output has increased and much trouble from broken springs has been eliminated. MS(10)

Spring Wire Specially Heat Treated. R. W. COOK (Wallace Barnes Co.). *Iron Age*, Vol. 126, Sept. 18, 1930, pages 764–766, 828.

The largest number of springs are made from steel on account of its desirable properties such as strength, elastic limit, toughness, stiffness and endurance. Through various combinations of cold work and heat treatment spring material having tensile strength as high as 400,000 lbs./in.^{2} is produced. Spring steel containing up to 1% C may be folded on itself either across or with grain. Patenting is done continuously in muffle furnace. Springs which are heat treated are seldom made from wire smaller than 10 gage. High-C steels susceptible to H embrittlement are never immersed in acid. Flat strips are sand-blasted. Quenched and tempered springs cannot be rust-proofed by a process which requires preliminary cleaning in acid. Gives a stress strain diagram of music wire, watch spring wire and tempered spring wire. VSP(10)

Heat-Treatment of Iron Nickel Alloys with Additions. (Thermische Behandlung von Eisen-Nickel-Legierungen mit Zusätzen.) P. CHEVENARD. *Zeitschrift Verein deutscher Ingenieure*, Vol. 74, Mar. 22, 1930, page 368.

Abridgement of a paper in *Comptes Rendus*, Vol. 189, 1929, page 846, on reversibly changeable alloys. See *Metals & Alloys*, Vol. 1, Oct. 1930, page 800. Ha(10)

Heat Treatment Continues to Advance. HERBERT M. BOYLSTON (Case School of Applied Science). *Iron Age*, Vol. 126, Sept. 11, 1930, pages 691–692.

Use of alloy steels has increased rapidly in last 25 years. Alloy steels are all carefully heat treated. New heat treatments of C steels have been developed with more careful heat control. Continuous normalizing furnaces have created a revolution in sheet steel business. Gives some of the recent papers on the subject with a brief abstract of each. Extensive research on Fe alloy is being made. X-ray spectrometry and radiography have added much to the study of the structure and defects of metals. VSP(10)

The Macrome Process of Steel Treating. *Machinery*, Vol. 37, Sept. 1930, page 52.

A process for increasing the cutting qualities of tool steel. Developed by the Macrome Steel Products, Birmingham, England claims increased life and greater ability to stand up under heavy pressure. Not a hardening process but a treatment added to the usual heat-treatment of steel. Increased life over ordinary steels is 25% for low C steels up to 300% for high speed tools. Process largely secret though it is known to be a low temperature pre-heating of tools in a closed chamber of gas. RHP(10)

Heat Treating Tables. *American Machinist*, Vol. 73, Aug. 28, 1930, page 367.

Gives table of fixed points for thermometer calibration commonly used in the heat treating department. Gives list of substances and temperature in both Fahrenheit and Centigrade of boiling point, melting point and solidification point. Table of drawing bath mixtures gives substances, melting temperature, and range. RHP(10)

Annealing and Quenching of Duralumin. (Remarque sur le recuit et la trempe du duralumin.) M. MATTER. *Revue de Metallurgie*, Vol. 27, Oct. 1930, pages 560–562.

The rate of cooling of duralumin strips 1–20 mm. thick placed on a rack in air was studied. It is inversely proportional to the thickness of specimens. Air cooling is sufficient to cause quenching effect equivalent to water immersion in sheets up to 2 mm. in thickness. Cooling faster than 150°/hr. gives a certain quenching effect. Quenching takes place on cooling to 200° so that it is possible to quench in molten nitrates at that temperature. JDG(10)

Temperature Control for Hardening Furnaces. *Machinery*, Vol. 36, June 1930, pages 768–769.

Apparently the same as "Tempering and Coloring Axes" by Wirt S. Scott. See *Metals & Alloys*, Vol. 1, Mar. 1930, page 428. RHP(10)

What Heat Treatment Has Done for Aircraft Engine Parts. R. R. MOORE (Wright Aeronautical Corp.). *Iron Age*, Vol. 125, Sept. 11, 1930, pages 677–679, 757.

Heat treatment improves the physical properties of metallic alloys. Recent developments of heat treating of Al alloys is responsible for much of the development of the aircraft. Two stages of heat treatment are the solution treatment and the aging treatment. Heat treating Al alloys has resulted in their displacing the heavy bronzes, Fe and steels. Gives tables showing the composition of light alloys and their improvement by heat treatment. Heat treating results are affected by small variations in chemical composition. Where resistance to elevated temperatures is desired, alloys known as "Y" and "Alco 122" are used. Heat treating duralumin, desirable properties are obtained by quenching in oil, air, warm water or cold water. Each of these treatments are adaptable to certain uses. Short-cut heat treatment leads to inferior properties. Aging at lower temperatures for longer periods, better physical properties are obtained. Complete aging produces maximum tensile strength and also considerable increase in proportional limit. Heat treatment has to a considerable extent lightened the construction of steel engine parts. Heat treatments also improve machinability. VSP(10)

Hardening (10a)

Forging Hardened Without Warping. *Iron Age*, Vol. 126, Sept. 4, 1930, pages 626–627, 675.

Describes simple home-made equipment used, which is giving satisfactory results. Carburizing pots are made of 16-in. cast Fe water pipe about 10 ft. long. Furnace is bottom-fired with oil. Six guides are treated at one time. A temperature of 1675° F. is reached in about 12 to 13 hr. firing. Uniform temperature is produced by a series of vents. VSP(10a)

Metal Surface Hardening. A. E. SHORTER. *Welding Journal*, Vol. 28, Nov. 1930, pages 333–340.

Paper before the Institution of Welding Engineers on Nov. 13, 1930. The paper discusses the "Shorter" process for surface hardening of gears, helicals, bevels and a great variety of pieces both as to form and size. The treatment consists of a heating by means of an oxy-acetylene blowpipe followed by a rapid quench. The process is entirely mechanical so that uniform results are obtained. AWM(10a)

Nonferrous Metal Hardening Process. *Brass World*, Vol. 26, Dec. 1930, page 327.

The "Hump" steel hardening process is now applied to Al and brass products. This process requires: a single-point recording potentiometer (or two-point combination recorder and recording controller), an electric furnace with manual control equipment and adjacent tank for quenching. Units are obtainable in multiple formation as well as singly. WHB(10a)

Hardening Tools. *American Machinist*, Vol. 73, Sept. 18, 1930, page 491.

Condensed summary of the fundamental hardening rules and of faults. RHP(10a)

Annealing (10b)

Normalized and Annealed Sheets. R. WHITFIELD. *Heat Treating & Forging*, Vol. 16, May 1930, pages 603–607, 613; Condensed in *Fuels & Furnaces*, Vol. 8, June 1930, pages 801–804.

Paper read before Iron & Steel Institute, May 1–2, 1930. See *Metals & Alloys*, Vol. 1, Oct. 1930, page 800. MS(10b)

Changes in Structure of Mild Steel on Annealing. W. HEIKE & W. BRENSCHEIDT. *Iron Age*, Vol. 126, Nov. 27, 1930, page 1605.

Abstract translation of article in *Stahl und Eisen*, Sept. 25, 1930. Annealing of mild steel in oxidizing atmospheres and the decarburization of outer sections is accompanied by formations of columnar crystals pointing from outer layer toward the center. Gives results of tests. See also *Metals & Alloys*, Vol. 2, Feb. 1931, page 40. VSP(10b)

Employs Salt Bath Annealing in Drawing Hollow Wire. *Steel*, Vol. 87, July 3, 1930, pages 62, 66.

Describes practice of Ellwood-Ivins' Steel Tube Works, Philadelphia, in the manufacture of extremely small-sized tubing such as hypodermic needles. Tubular Cr-Mo (S.A.E. 4130 or 4140) billets, 2–3 in. outside diameter, are given 60–75 cold draws, with an anneal before each draw, to reduce the outside diameter to 0.009 in. and the wall thickness to 0.001 in. Annealing is done in a salt bath heated by electrodes immersed in the liquid. The bath is held at 1400° F. before receiving the work. MS(10b)

The Fundamentals of Successful Strip Brass Annealing. CHARLES K. SKINNER (Gen. Elec. Co.). *Metal Industry*, N. Y., Vol. 28, Sept. 1930, pages 420–422.

Confined to annealing in large batch type furnace of the side-top-fired oil burning type. The variables which influence the result of heat treatment of brass are: (1) furnace design; (2) burners; (3) pyrometric equipment; (4) annealing; (5) firing; (6) metal; (7) loading of pans; (8) sampling; (9) time of anneal; (10) fuel. Discusses each. VSP(10b)

Case Hardening & Nitrogen Hardening (10c)

Influence of Nitrogen on Special Steels. S. I. SATOH. *Fuels & Furnaces*, Vol. 8, April 1930, pages 523–526.

From paper read before American Institute of Mining & Metallurgical Engineers. See *Metals & Alloys*, Vol. 1, March 1930, page 429. MS(10c)

Bell-Type Nitriding Furnace Has Been Recently Developed. *Electric Journal*, Vol. 28, Jan. 1931, page 40.

In an electric nitriding furnace, the objects are put inside a stationary box, through which ammonia gas can be circulated by permanent piping, both box and piping being constructed of solid nickel. To make the box gas-tight, the edges of its cover are turned downward dipping in a trough of molten Pb. The Pb is melted by tubular heaters built into the trough. Then, over the box, a crane sets the 7$^1/_2$ ton-bell—heavily insulated and lined with heating elements. Base, box and 3500-lb. charge can be brought from room temperature to 1000° F. in 6 hrs. by the input of 75 kw., 220-volts, 3-phase, after which that temperature can be maintained by only 11.5 kw. In continuous operation, the bell need never get cold, as one bell serves 2 bases and 2 nitriding boxes alternately. WHB(10c)

Annealing or Softening of Nitrided Steels by Chemical Decomposition of the Nitride. W. J. MERTEN. *Fuels & Furnaces*, Vol. 8, Feb. 1930, pages 199–200.

Drawing (10e)

Carbide Precipitation during Drawing of Corrosion Resistant Non-Magnetic Chromium Nickel Steel. B. STRAUSS, H. SCHOTTKY & J. HINNÜBER. *Metals & Alloys*, Vol. 1, Oct. 1930, pages 785–787.

A translation. Original in *Zeitschrift für anorganische und allgemeine Chemie*, Vol. 188, Mar. 1930, pages 309–324. ESC(10e)

Aging (10f)

Reactions during Age Hardening. (Die Vorgänge bei der Vergütung.) G. TAMMANN. *Zeitschrift für Metallkunde*, Vol. 22, Nov. 1930, pages 365–368.

Tammann discusses the theory of Merica who ascribes the phenomenon of age-hardening to the blocking of lattice planes due to highly dispersed precipitations and the loss of age-hardening to the coagulation of the dispersions. This conception, transferred from the fields of colloid-chemistry, does not suffice for Tammann who supports his statements by mathematical derivations. He assumes in addition to Merica's assumptions that the slip of the dispersions is rendered more difficult in the adjacent parts. A clear atomistic interpretation is not possible at the present time. Tammann discusses the gathering of the excess atoms in super-saturated solid solution resulting in a notable change of properties. This he demonstrates by means of several typical examples taken from chemical and metallurgical fields. The position and form of the dispersion from super-saturated solid solutions exert a large influence upon the increase of strength during age-hardening. The author urges further microscopic examinations of the shrinking needle-like segregations and of their growing, as studied in the case of cementite lamellae, in Ni-Si, Co-Si solid solutions and in Cu-Al alloys. 11 references. JOINING OF METALS & ALLOYS (11)

Brazing (11a)

Brazing Operations. A. Eyles. *Brass World*, Vol. 27, Jan. 1931, page 7.

Brazing is preferable to welding for making joints or repairing products made of brass, bronze or malleable iron. Precautions and operations are outlined and the composition of solders for brazing soft and hard brass, copper, iron and steel tabulated. WHB(11a)

Multiple-Joint Brazing in Hydrogen Atmosphere. H. M. Webber (General Electric Co.). *American Machinist*, Vol. 73, Oct. 30, 1930, pages 697–699; Nov. 6, 1930, pages 745–747.

Brazing is very successful. Cu and Fe have a strong affinity for each other at 2100° F. The H atmosphere within the furnace cleans oxide film and some impurities from the surface of the Fe giving a good brazing surface. Maximum tolerance for gap to be brazed is about 0.003 in. Pressure applied to the joint increases strength as the Fe tends to grow together. 4 effects impart strength to a Cu brazed joint, i. e., the alloying of the Cu with the Fe, alloying of Fe with the Cu, penetration of Cu along the grain boundaries, and the grain growth across the joint. The accumulation of these effects produces in most cases a joint as strong as steel itself. Strains seldom result from brazing. Stainless steels cannot be brazed in this way. W, Mo and tungsten carbide alloys may be brazed this way. Gray cast Fe has to be heated in the air to oxidize the surface before putting in the furnace for brazing. Malleable cast Fe is more easily brazed. The second part of the article deals with methods of brazing, equipment, costs, and time required for the work. RHP(11a)

Soldering (11b)

The Composition of Silver Solders. (Die Zusammensetzung von Silberloten.) Ralph J. Snelling. *Deutsche Goldschmiede-Zeitung*, Vol. 33, Nov. 15, 1930, pages 543–544.

Silver solders usually are Ag-Cu or Ag-Cu-Zn alloys. The Zn lowers the melting point, but decreases the strength and ductility. An alloy containing 65% Ag, 20% Cu and 15% Zn melts at 695° C. and has good properties. For use on second quality articles the solder may contain only 25 or 30% Ag. Several percent of Cd can be added to silver solders to advantage. Sn or Ni are also sometimes used. Fe and other impurities should be carefully avoided. JLG(11b)

Welding & Cutting (11c)

Welding with the Electric Arc. (Auftragsschweissung mit dem elektrischen Lichtbogen.) K. Tewes. *Giesserei Zeitung*, Vol. 27, Nov. 1, 1930, pages 585–589.

The author deals in general with the metallurgical and electrical sides of the problem of welding and gives, in the second part of his book, practical results in welding rails. Different types of electrodes were used in the tests; one with the composition, C : 1.10%; Si : 0.25%; Mn : 0.25%; P: 0.04%; S: 0.03%, proved most successful. The author takes his stand against the application of austenitic Mn rails. The use of a Ti steel filling rod is favored. This is abstracted by F. Rapatz in *Stahl und Eisen*, Vol. 50, Oct. 16, 1930, pages 1474–1475. GN(11c)

The Importance of Burning Depth in Arc-Welding and the Means for Its Improvement. (Die Bedeutung der Einbrandtiefe beim Lichtbogenschweissen und die Mittel zu ihrer Verbesserung.) Ernst Schwarz. *Zeitschrift Verein deutscher Ingenieure*, Vol. 74, Nov. 15, 1930, pages 1565–1567.

When welding with direct current, the burning depth is influenced by the following conditions: (1) the polarity must be right; welding rods with high C contents should be connected to the positive; (2) welding rods of high C contents have a lower burning depth than those with low C; (3) the burning depth can be increased to a certain degree by a reduction in velocity of advance and an increase of current; (4) a welding dynamo which gives higher current peaks in welding (as shown in an oscillogram) is preferable; (5) the burning depth for butt-welded joints and surface welds should be at least 2 mm.; (6) in V-welds, the burning depth must be at least so great that hollow spaces at the bottom of the angle are avoided. Ha(11c)

Strength and Structure of Welds. (Festigkeit und Gefüge von Auftragschweissungen.) O. Dahl & S. Sandelowsky. *Stahl und Eisen*, Vol. 50, Nov. 20, 1930, pages 1639–1642.

The various applications of welding with a filling rod are described and the results are given of investigations which the authors have carried on with 8 different welding rods. The results of hardness tests and metallographic studies are discussed. GN(11c)

Steel Mill Applications of Thermit Welding. H. Deppeler. *Rolling Mill Journal*, Vol. 4, Mar. 1930, pages 93–94.

Abstract of a paper read before the American Iron & Steel Institute. See *Metals & Alloys*, Vol. 1, Feb. 1930, page 387. MS(11c)

Electric Welding as Applied to Railway Bridges and Other Structures. H. Bruff. *Engineering*, Vol. 128, Nov. 22, 1929, pages 687–689; Nov. 29, 1929, pages 719–722.

Condensed from paper read before the Junior Institution of Engineers, Oct. 25, 1929. Points out advantages of repairing worn-out bridges by means of electric welding. Describes actual welding process carried out in attempt to procure data on strength of such welds. Same process has been successfully used for constructing new structures, for making bridge floors watertight, for repairing worn railroad track crossings, and for the repair of worn-out coal spouts. Discusses problem of stress encountered when fluid metal is deposited on material already strained as in case of strengthening weak bridges. See also editorial on page 711 and letter on page 781. LFM(11c)

Progress of Welding Technique in Steel Structures. (Fortschritte der Schweisstechnik im Stahlbau.) H. Schmuckler. *Zeitschrift Verein deutscher Ingenieure*, Vol. 74, Nov. 15, 1930, pages 1573–1579.

The safety of welded steel structures is discussed and certain suggestions are offered for improvements in the regulations for welded high structures. A few simple examples of calculations and formulas are given which can serve as a basis for calculaton. A new simple arrangement is described and a table is given on which the structural steel parts can easily be put together for welding. Illustrations of actual constructions are reproduced. Ha(11c)

Strength Investigations on Welded Beam Connections. C. H. Jennings & A. A. Jakkula (Westinghouse Elec. & Mfg. Co.). *Journal American Welding Society*, Vol. 9, July 1930, pages 64–70.

Electric Welds in Mild Steel. (Sur les soudres enacier doux déposées à l'arc électrique.) D. Rosenthal & M. Mathieu. *Comptes Rendus*, Vol. 191, Sept. 22, 1930, pages 484–486.

Impact tests have shown that the brittleness of welds in mild steel depends to a large extent on the manner in which the metal is protected against atmospheric oxidation during fusion. Authors have tested welds made (a) with bare wires, and (b) with coated wires, with the following results:

Electrode	No. of Sample	Section at bottom of notch in cm.²	Impact number kgm/cm.²	Remarks
Bare mild steel wire	113 B1	0.485	0.82	Crystalline fractures
	113 B2	0.49	0.81 (5)	
	113 B3	0.5	1.0	
	113 B4	0.47	0.96	
Ordinary coated electrode	T2–1	0.51	7.60	Fractures fibrous, slightly crystalline at centers
	T2–2	0.47	7.55	
of good quality	T2–3	0.5	6.80	Fractures fibrous, crystalline at centers
	T2–4	0.48	5.85	

The table emphasizes the great difference in the resistance to impact of welds made with the 2 types of electrode. Micro-examination showed that the use of coated electrodes resulted in structures more regular in appearance, than those obtained with the bare wires, but threw little more light than this on the matter. Examination of the welds under the K-indication of a molybdenum anti-cathode resulted in diagrams differing quite markedly in appearance. The diagrams from the bare wire welds sometimes indicated slight orientation and in all cases showed very pronounced asterism. These from the coated electrode welds showed no evidence of orientation and but slight signs of asterism. Conclusion is that the existence of internal stresses in the welds made with uncoated electrodes is thus made manifest. OWE(11c)

Riveting (11d)

How Riveting is Keeping Pace with Advance in Industry. A. F. Jensen (Hanna Engineering Works). *Iron Trade Review*, Vol. 85, Nov. 28, 1929, pages 1379–1381.

From paper read before American Institute of Steel Construction, Nov. 14, 1929. Gives several examples of speeding up driving of rivets in all types of construction by means of new equipment. Cold driving is gaining favor. Advocates a thorough investigation of stresses in rivets to bring information up to date. Outlines a program of research. MS(11d)

Riveting in Metal Airplane Construction. (Nietverfahren in Metallflugzeugbau.) Wilhelm Pleines. *Luftfahrtforschung*, Vol. VIII, Apr. 1930, pages 1–72; translated in *National Advisory Committee for Aeronautics Technical Memoranda* Nos. 596, 597, 598 and 599, Dec. 1930.

The articles describe in detail the procedure and practice used in Germany for designing and manufacturing riveted joints for airplanes. The rivets are generally used with aluminum alloys (duralumin) and are manufactured of a similar material. The sizes vary from $^1/_{16}''$ to $^5/_{16}''$ in diameter. All rivets are driven cold. There are many descriptions and illustrations of apparatus and joints used by the leading airplane builders, Junkers, Rohrbach and Dornier. Ingenious dollies and jigs are used for backing up rivets inside of tubes and hollow members. Press and machine riveting is used wherever possible. The eccentric press, maximum 13,000 lbs., requires a rivet $^1/_{16}''$ to $^3/_{32}''$ longer than a hand driven rivet. The diameter of the hole for machine driven rivets is 0.010″ and for hand driven 0.004″ larger than the rivet shank. Special devices are attached to the machine to prevent thin sheet from crimping at the rivet hole and to guide the rivet during driving so that it will not become cocked. Riveting by compressed air hammers involves a danger from the dolly recoil damaging the sheet. (American manufacturers use air hammers as much as possible, as approximately 8 rivets can be driven by this method to one by hand.) American devices for absorbing the shock of riveting are referred to, Junker uses an automatic time release and an air closing device with foot lever operation. The quality of riveting is determined by visual inspection of the rivet heads and determination of the thickness of the driven head by gages. Illuminated mirrors are used for the inside of tubes and similar members. Each manufacturer uses his own rivet standards. References made to S.A.E. standardization of duralumin rivet heads in the United States. The tolerances permissible for the diameter and length of the shank are given. Rivet head eccentricity is held to 5% of the body diameter with 0.013″ as maximum. Stock rivets over 0.4″ in length are graded for every 0.08″ although there is a demand for 0.04″ gradation. Rivets are heated at 500° to 520° C. (930° to 968° F.) from 10 to 15 minutes. Method of quenching not given. For emergency repair 420° C. (788° F.) is used as the rivets can be driven at any time, whereas the higher temperatures cause age hardening and the rivets can only be used up to 5 hours. The standard formulas for design of joints are given. The methods of determining allowable stresses for riveted steel structures does not apply as there is no well defined yield point in duralumin and to use the factors used for steel would increase the weight of the structure more than necessary, as demonstrated by actual service. A shearing strength for the rivet of from 35,000 to 38,000 lbs./in.² is recommended for design. The shearing strength depends upon the method of driving.

Average Shearing Strength of Duralumin Rivets in lbs./in.²

Plain	Hand Driven	Machine Driven
Not Driven	7 oz. Hammers 16–18 Blows	Eccentric Press, 13,200 lbs.
31,500	37,000	47,000

The allowable stress for the crushing of duralumin sheet at the edge of the rivet hole is 85,000 lbs./in.² Tests indicate much higher values before failure but the enlargement of the hole is considerable at even lower stresses. The crushing strength of the thin plates less than 0.04″ in thickness was lower than the thicker plates with a steel bolt through the rivet hole, but when tests were made on driven rivets the heads supported the thinner sheets so that the crushing value was equal to that of the thicker sheets. When the distance from the edge of the hole to the edge of the plate exceeds 2 times the hole diameter the crushing strength is constant and equal to approximately 160,000 lbs./in.² The application of a tensile or compressive stress to a riveted joint extends the hole in the direction of the load. The allowable amount of extension is problematic and can only be settled by a series of alternating impact tests as it is under this type of loading that the hole enlargement has a serious weakening effect. A hole enlargement of 1% is obtained with crushing values of from 47,000 to 65,000 lbs./in.² The enlargement of the rivet hole by expansion of the rivet shank when the rivet is driven lowers the resistance to crushing and must be guarded against, especially on thin sheets. JBJ(11d)

The DeBergue Patent Countersunk Riveting Process. *Sheet Metal Industries*, Vol. 4, Oct. 1930, pages 458–460.

The process is suggested for sheets up to $^1/_8$ inch thick. The company prefers to limit mild steel sheets to 14 gage. The process yields a joint in thin metal with one surface flush and possessing about twice the strength of a standard joint with ordinary cup-head rivets. The sheets are interlocked so that they cannot slide and the shear stress is therefore removed from the rivet shanks. AWM(11d)

WORKING OF METALS & ALLOYS (12)

Melting & Refining (12a)

Study on Basic Open-Hearth Slags and Their Charting. *Iron Age*, Vol. 126, Oct. 23, 1930, page 1159.

Taken from a paper read at the British Iron and Steel Institute meeting in Czechoslovakia by Otakar Quadrat on "A Contribution to the Problem of the Analysis of Basic Slags and the Representation of Their Composition in a Triangular Diagram." Proposal of a method for showing by diagram the characteristics of a basic slag. See *Metals & Alloys*, Vol. 1, Dec. 1930, page 915. (12a)

Melting Steel in a Brackelsberg Furnace with Acid Lining. P. BARDENHEUER. *Foundry Trade Journal*, Vol. 43, Oct. 23, 1930, pages 285–286; *Fuels & Furnaces*, Vol. 8, Aug. 1930, pages 1049–1054, 1114.

See *Metals & Alloys*, Vol. 2, Feb. 1931, page 42. MS(12a)

"Two Speed" Melting Shop Management—or Steady Average. WALTER LISTER. *Metallurgia*, Vol. 3, Nov. 1930, pages 1–3, 8.

In steel melting practice it is uneconomical to attempt to make record production if such speed necessitates extensive repairs. Describes correct melting practice and management in detail. JLG(12a)

Making Malleable Iron by the Duplex Melting Process. B. R. MAYNE. *Fuels & Furnaces*, Vol. 8, June 1930, pages 783–786.

From paper read before the American Foundrymen's Association, May 12–16, 1930. MS(12a)

Advice on Fluxing Aluminum. *American Metal Market*, Vol. 37, No. 240, Dec. 13, 1930, page 4.

A bulletin by the National Smelting Co. discusses the fluxing of aluminum. A good flux for aluminum melting should contain 2 salts—one with a low melting point and the other with a high one to retard the thermit reaction when it becomes too rapid. For large furnace operation other fluxes have been developed. The flux should be of low specific gravity, and should not pick up moisture when stored. WHB(12a)

Favors Electric Furnaces for Special Steels. *Electrical World*, Vol. 96, Dec. 27, 1930, page 1184.

Electric furnace operation is closely controlled yet flexible and excludes oxygen from the melting process. The Chicago Steel Foundry Co. manufactures "Pyrasteel" designed for high temperature uses and "Evansteel," made in various grades of hardness, tensile strength and elastic limit. Both steels are classed as Ni-Cr alloys. The electric furnaces used are both of the open-roof type. The general features of the 2 furnaces are indicated by pictures and drawings. WHB(12a)

Preventing Unsoundness in Bronzes and Red Brass. *Foundry*, Vol. 58, Aug. 1, 1930, pages 84–87, 109.

Metals having good fluidity, low contraction, pour clean and are not greased easily, are easiest to cast sound. Greatest difficulty encountered in production of sound bronze and red brass castings, including Cu-Sn, Cu-Sn-Zn and Cu-Sn-Zn-Pb alloys is trouble from internal sponginess or porosity. Porosity in bronzes and red brasses has been attributed to oxidized metal. Reducing atmospheres have a deleterious effect on the metal and may produce incipient shrinkage in some bronze alloys. Considers operating characteristics of several commercial furnaces, reactions of gases on Cu and structural characteristics of the alloys. Typical combustion reactions of the various gases are:

$$CH_4 + 4O = CO_2 + 2H_2O + \text{Heat}$$
$$2CO + O_2 = 2CO_2 + \text{Heat}$$
$$2H_2 + O_2 = 2H_2O + \text{Heat}$$

An oxidizing atmosphere may consist of 4% O, 13% CO_2 and remainder N. Neutral melting atmospheres necessitate proportioning burners which maintain ratio of fuel to air constant. VSP(12a)

Open-Hearth Operators Discuss Basic and Acid Practice. *Iron Trade Review*, Vol. 86, May 29, 1930, pages 54–55.

Report of the 11th semi-annual meeting of the open-hearth committee of the American Institute of Mining & Metallurgical Engineers, May 21–23, 1930. MS(12a)

Fabrication of the Platinum Metals. C. S. SIVIL (Baker & Co.). *Preprint, American Institute of Mining and Metallurgical Engineers*, 1931, 15 pages.

Platinum was formerly fabricated by hot forging of the sponge, and this method is still used to a limited extent in Europe. It can be melted in the oxyhydrogen flame, arc furnace, induction furnace or by the atomic hydrogen torch. Hydrogen hardens, but does not prevent working. Gases, particularly oxygen, affect the properties. Carbon is very deleterious. Lime is the most generally used refractory for melting Pt. Both Pt and Pd can be easily worked either hot or cold. The softening temperature for cold worked Pt is 650° C. In making wire Pt or Pd are either rolled or swaged to bars suitable for drawing in tungsten carbide dies. Bare wire can be drawn as fine as 0.0004 in. Rhodium can be worked with difficulty. Iridium is even more difficult to work. Ruthenium and Osmium have not been worked. Contains 15 references. JLG(12a)

Investigation of the Thomas Process. (Untersuchungen über die Vorgänge beim Thomasverfahren.) KURT THOMAS. *Stahl und Eisen*, Vol. 50, Nov. 27, 1930, pages 1655–1674; Dec. 4, 1930, pages 1708–1718.

Report 196 of the Steel Mill Committee of the Verein deutscher Eisenhüttenleute. Includes discussion. The investigation was undertaken to determine the influence of the shape of the converter on the process of blowing, i. e., on the time of blowing, the metal loss through oxidation and mechanical causes and the increase of temperature of the charge. About 50 heats were tested to establish the above relations For this purpose, during the course of one campaign, the weight of the charge was changed to obtain similar conditions as regards the height of the bath in the converter and the converter volume available/ton of input. The results confirm the known fact that a high charging temperature of pig Fe is favorable; a minimum temperature of 1250° C. should be used. No reliable relations could be established between time of the blow and height of the bath, air volume and pressure, and converter volume/ton of the charge. It is shown, however, that the time of blow is essentially decreased when the "cross-section of circulation"/ton of the charge is increased. The "cross-section of circulation" (Umlaufsquerschnitt) is defined as the relation between the cross-section of the bath and the cross-section of blow. The time of the blow could be reduced by 20% when the "Umlaufsquerschnitt" was increased from 1100 to 2400 cm.²/ton of charge. This also resulted in a decrease of the mechanical metal loss. The time of blow of cold charges is influenced more by the "Umlaufsquerschnitt" than that of hotter charges. The large "Umlaufsquerschnitt" has no unfavorable bearing on the increase of the temperature during the blow. It is concluded that the amount of CO_2 of the waste gases increases with increasing "Umlaufsquerschnitt" which was proven by investigating the air consumption/kg. of additional elements. GN(12a)

Debismuthizing Lead with Calcium. RALPH F. COHN. *American Electrochemical Society, Preprint* 59–2, April 1931 Meeting, 6 pages.

Desilverized lead containing 0.1% Bi is not suitable for white lead manufacture. The Betts' electrolytic lead process for the elimination of the Bi is applicable, but the new process herewith presented is more economical. Metallic Ca is introduced into molten Pb. A Ca-Bi dross is formed. The Bi in the Pb is reduced to less than 0.05%, and the last traces of As, Sb, Ag and Cu are scavenged. The slight excess of Ca remaining in the Pb is removed with Cl. The dross is submitted to the Betts' process. The theory and economics of the new process are discussed at length. (12a)

Production and Remelting of Brasses. EDMUND R. THEWS. *Metal Industry*, London, Vol. 37, Sept. 12, 1930, pages 241–242; Sept. 26, 1930, pages 293–294, 296.

Prevention of the loss of large percentage of Zn by oxidation has been reduced to about ½% or less by the introduction of the electric furnace. In melting and remelting brasses following types of furnaces are used: (1) reverberatory furnace (coal, gas and oil); (2) Crucible furnace (coal, gas and oil); (3) electric furnace (electric arc and induction type). A correctly built brass melting furnace should fulfill following requirements: (1) loss of Zn by oxidation should not exceed 1½% with crucible furnaces and ½% with electric furnaces; (2) remelting brasses should not cause the mechanical and chemical properties of the alloys to deteriorate; (3) furnaces should possess as large a productive capacity as possible. Effect of SO_2 and superheat is injurious. Excessive loss of Zn may also be prevented by protecting surface against oxidizing influence of air. Addition of Al and Mg has unfavorable influence on mechanical properties and on appearance of metal surface. Electric brass melting furnaces will give best results obtainable. Recovering flue dust and heat distribution and control are discussed. VSP(12a)

The Influence of Solid and Liquid Pig Iron on the Operation of the Open-Hearth Furnace. (Einfluss von flüssigem gegenüber festem Roheisen-einsatz auf die Betriebsverhältnisse im Siemens-Martin-Werk.) F. WEISGERBER. *Stahl und Eisen*, Vol. 50, Oct. 23, 1930, pages 1489–1495. 3 references.

Report 194 of the Steel Mill Committee of the Verein deutscher Eisenhüttenleute. Includes discussion. 20–30% of liquid pig iron in the charge of the open-hearth furnace increase the furnace output by about 10%, decrease the consumption of pig iron by 10% and the fuel consumption by about 15%. The lime consumption decreases somewhat, whereas the consumption of dolomite increases to a certain extent. Liquid pig iron does not impair the quality of the steel. Considered from the economic point of view, the use of liquid pig iron offers only advantages. GN(12a)

Bath Reactions in Pulverized Coal-Fired Air Furnace. E. F. WILSON. *Fuels & Furnaces*, Vol. 8, June 1930, pages 857–858.

From paper read before the American Foundrymen's Association, May 12–16, 1930. MS(12a)

The Relation between the Manganese Contents of Liquid Steel and the Slag. (Die Beziehungen zwischen den Mangangehalten des flüssigen Eisens und der Schlacke.) H. SCHENCK. *Stahl und Eisen*, Vol. 50, Sept. 25, 1930, pages 1363–1364.

Abstract of a paper by G. Oishi presented before World-Engineering Congress, Tokyo, Oct. 1929. In order to establish the above relations, the author evaluated the analytical results of a group of laboratory tests as well as the results obtained on acid and basic open hearth melts. In determining the equilibria, 30–50 g. of electrolytic Fe were melted in porcelain crucibles, to which small amounts of silica, manganese oxide and ferrous oxide were added. In a further group of tests, the conditions of equilibrium were changed by adding lime to the slag. After melting, metal and slag were subjected to a temperature of 1550° C. for 3 to 10 min. The results of 2 acid and 2 basic heats are described in some detail. The relation of the total concentration of MnO and FeO $\frac{(\Sigma\ MnO)}{(\Sigma\ FeO)}$ is plotted in diagrams against the Mn content (Σ N Mn) of the steel. This relation holds providing the Mn content does not exceed 0.3%. GN(12a)

American Investigations on the Physical Chemistry of the Steel Processes. (Amerikanische Forschungsarbeiten über die physikalische Chemie der Stahlerzeugungsverfahren.) H. SCHENCK. *Stahl und Eisen*, Vol. 50, Dec. 18, 1930, pages 1782–1786.

Critical review of the latest publications by C. H. Herty. GN(12a)

Progress in Basic Open-Hearth Practice. *Blast Furnace & Steel Plant*, Vol. 18, Jan. 1930, pages 114–115.

Quality steel is being produced under quantity conditions through better operating practice. Open-hearth charge, proper slag condition, quality fuel, etc. are important factors in making good steel. If steel is not clean at tapping, adding deoxidizers afterward will not improve the quality. Hennig Purifier is claimed to be beneficial, as it degasifies and desulphurizes the metal. By taking proper care of molds, better surfaced ingots are produced. MS(12a)

Economics of the Various Refining Agents in the Open Hearth Process. (Untersuchung über die Wirtschaftlichkeit verschiedener Frischmittel für das Siemens-Martin Verfahren.) S. SCHLEICHER. *Stahl und Eisen*, Vol. 49, Apr. 4, 1929, pages 458–464.

Report 162 of the Steel Mill Committee of the Verein deutscher Eisenhüttenleute. Includes discussion. The decarburization of a steel bath by adding ore was studied to determine the economics of various refining agents. The results show that the decrease of C in the bath is approximately a linear function of the time. The O content has no bearing on the velocity of refining. However, it determines the amount of the refining agent to be used. The Si content is of importance inasmuch as it regulates the amount of CaO to be added and the loss by oxidation. It is shown that, based on the chemical analysis of the refining agent and its price, its economical use can be calculated in advance, due to the above mentioned linear function of the decrease of C. In the case that larger amounts of ore are added than are necessary to oxidize the amount of C in a certain short time interval, part of the Fe content of the ore is slagged. GN(12a)

The Composition of Basic Open Hearth Slags. (Gesetzmässigkeiten in der Zusammensetzung basischer Siemens-Martin Schlacken.) S. SCHLEICHER. *Archiv für Eisenhüttenwesen*, Vol. 4, Nov. 1930, pages 239–244; *Stahl und Eisen*, Vol. 50, Dec. 18, 1930, pages 1778–1779.

The relations between the various components of basic open hearth slags have been established in examining 29 slags. The amount of MnO is lower in higher basic slags than in less basic slags. The Fe content of slags decreases with increasing acid components. The amount of MnO varied between 27.95 and 12%. The average total amount of MnO, CaO and MgO in the 29 slags analyzed is 61.4% which indicates that CaO and MgO can be replaced in basic slags by MnO. It is furthermore shown that there exists a relation between the Fe content and the content of SiO_2 and P_2O_5. The Fe content of the slags decreases with increasing amount of SiO_2 and vice versa. The above relation holds for the slags of low C steels up to 0.20 C. In slags of higher C steels the total of MnO + CaO + MgO amounts to about 65.5%; but the relation between MnO and CaO and MgO is preserved. By determining only the Mn and Fe content of a basic open hearth slag, the theoretical analysis can be approximately calculated. GN(12a)

The Open-hearth Steel Process as a Problem in Chemical Kinetics. ERIC R. JETTE (Columbia University). *Technical Publication* No. 380, *American Institute of Mining and Metallurgical Engineers*, 1931, 34 pages.

Complete knowledge of a chemical process requires not only an understanding of the thermodynamics of the reactions, but also a knowledge of the mechanism and kinetics. An attempt is made to develop an equation for the kinetics involved in the steel making process. The mechanism is not certain, but the most probable assumption is that it can be explained by the equation $FeO + C \rightleftharpoons Fe + CO$. On this basis an equation is developed and critically discussed. It is probable that the rate of diffusion of FeO from slag to metal is a governing factor, and this rate is very difficult to predict. As long as open-hearth heats are finished with oxidizing slags the steel will be overoxidized. Contains 17 references. JLG(12a)

Rolling (12c)

Modern Chilled Iron Rolls. W. H. MELANEY. *Rolling Mill Journal*, Vol. 4, Apr. 1930, pages 143–144, 153–154; May 1930, pages 237–240; June 1930, pages 291–293; July 1930, pages 371–373; Sept. 1930, pages 469–470, 473–474.

Face of chilled rolls has a hard, white, brittle crystalline structure, all of the C being in the combined state. Center consists of a dark gray granular formation in which there is a net-work of combined C filled in with specks of graphite. This has the hardness of ordinary cast Fe. Between the face and center there is a formation, known as "spray," which has an appearance and characteristics half-way between those of the other 2 structures. Rolls become convex during rolling due to the uneven expansion of the middle and ends. To correct this, the roll face parallel is made slightly concave. The hotter the roll is operated, the greater the concavity required. The harder the face and the greater the depth of chill, the greater will be its expansion at a given temperature. The longer a roll has been in service, the less will be its expansion under the same conditions. Expansion of center of roll is only about half that of face. This difference causes stretching of the center and, if heating is rapid, rupture with eventual breakage of the roll in service. By selecting rolls with a hardness just sufficient to give the surface desired, danger of breakage will be reduced. Mild-chilled faces are applicable to right-pack rolling. For highly finished surfaces, hard-faced rolls are used at relatively lower temperatures. The rolls must be preheated slowly to their rolling temperature before the work is started. Preheating time is determined largely by the mass of the roll. Diagonal breakage is usually due to deep chill or to a close spray extending quite a depth into the body of the roll. The harder the roll, the more susceptible it will be to this type of breakage. Roll failure may be caused by spalls, due to excessive pressure arising from such conditions as having the screws forced down too tightly and accidental rolling of cold material. If rolls become concave during service, it will usually be found that the necks are becoming too hot, from lack of lubrication, insufficient bearing area or the lifting of the necks clear of their bearings by the wedge action of the fillets caused by the rolls having become too tight endwise. A slight tapering of the necks is advantageous. Usual condition during rolling is for face to become convex. Proper use of steam on center of face will remedy this. MS(12c)

Scleroscope Hardness of Chilled Rolls. W. H. MELANEY. *Blast Furnace & Steel Plant*, Vol. 18, Jan. 1930, pages 100–101.

Hardness of face of a roll should be based on type of work to be produced. Where tail marks cannot be tolerated, it is necessary to have a harder face than in other cases. A roll should not be harder than is essential for proper results, due to the greater expansion and greater liability to breakage of hard rolls. The scleroscope has been suggested as an instrument for determining the proper hardness. However, scleroscope hardness is no criterion of the performance of a roll, and, in fact, is often misleading. The physical structure of the roll body beneath the chilled surface, and the depth of chill are the important factors in determining the service obtainable from a roll. MS(12c)

Improved Method of Piling Cold Rolled Sheets. *Rolling Mill Journal*, Vol. 4, March 1930, pages 95–98; *Iron Trade Review*, Vol. 86, March 20, 1930, pages 52–53; *Blast Furnace & Steel Plant*, Vol. 18, April 1930, pages 646–647.

Description of a tin-plate piling machine, which is substantially automatic in operation. It was developed by the American Sheet & Tin Plate Co. Construction features include runout, edging, and incline conveyors, positioning fingers, and hydraulically spotted transfer car. MS(12c)

The Filling of Passes in Rolling Steel. (Das Füllen der Kaliber.) W. TAFEL & G. WAGENER. *Stahl und Eisen*, Vol. 50, Jan. 30, 1930, pages 126–128.

The authors reply in this paper to Eklund's method of calculating the height of an ingot or billet required to fill the pass and show, by carefully checking this method with the one which Tafel has developed, that though both methods are equally simple, Tafel's method is superior owing to a greater accuracy. Roll Pass Design. Pt. XIII–XXIV. W. TRINKS (Carnegie Institute of Technology). *Rolling Mill Journal*, Vol. 4, Jan. 1930, pages 15–18, 25–26; Feb. 1930, pages 49–53; Mar. 1930, pages 103–106; Apr. 1930, pages 139–142; May 1930, pages 241–244; June 1930, pages 295–296; July 1930, pages 359–360, 378; Aug. 1930, pages 415–416; Sept. 1930, pages 465–468; Oct. 1930, pages 549–552; Nov. 1930, pages 615–617; Dec. 1930, pages 665–668, 672.

Deals with methods of overcoming effects of non-uniform reductions in the rolling of non-symmetrical sections; conditions which cause fins and over fills and methods of avoiding them; amount and effect of wide work due to edging and to flange rolling; methods of avoiding trouble in rolling flanged sections; effects of live passes and dead holes on side work; factors affecting the magnitude of side pressure for rectangular and wedge-shaped passes; causes and effects of thrust in symmetrical and non-symmetrical roll passes; calculation of end thrust; method of determining bearing area which takes end thrust due to rolling in non-symmetrical passes; application of interlocking collars to rolls for taking up end thrust; bending of a section by rolls or guides; influence of difference in roll diameters on prevention of collars and protection of table rolls; action of forces when diameters differ; roll length; arrangement of passes on rolls; pass design for performing slitting operations in various types of sections in hot rolling; and rolling of square or nearly square sections in blooming-mill passes. MS(12c)

Forces Acting on Roll-Neck Bearings. W. TRINKS & J H. HITCHCOCK. *Iron Age*, Vol. 126, Dec. 4, 1930, pages 1677–1679, 1748.

Abstract of a report of the special research committee on heavy-duty antifriction bearings, read before the Iron and Steel Division of the American Society of Mechanical Engineers. In anti-friction bearing design the accurate average load and approximate maximum load must be known. Average pressure in hot rolling depends on temperature, composition, compression rate, internal friction and friction between bar and rolls; in cold rolling on elongation, compression rate, composition of bar, modulus of elasticity of roll and internal friction of bar. VSP(12c)

Anti-Friction Bearings in the Equipment for Making Wire. F. WALDORF (Timken Roller Bearing Co.). *Wire & Wire Products*, June 1930, pages 223–224, 242–244; July 1930, pages 270–271.

The author gives an illustrated description of roller bearings on roughing and finishing stands, drawing blocks, stranders and other machines. GN(12c)

New Forms of Bearings for Rolling Mills. (Neue Gleitformenlager in Walzwerken.) H. WEINLIG. *Stahl und Eisen*, Vol. 49, Oct. 31, 1929, pages 1573–1579.

Report 71 of the Rolling Mill Committee of the Verein deutscher Eisenhüttenleute. Includes discussion. The paper reports the results of investigation of new forms of rolling mill bearings carried on by the Röchling Iron and Steel Works at Völklingen, Saar district. Before referring to the results of tests with hard wood bearings, the disadvantages of antifriction bearings are outlined. Among them are especially mentioned the high first cost and the high cost of maintenance. The successful application of the new bearing depends on the quality of the wood used. Detailed information on the determination of the quality of the wood is given. The new bearing has been successfully applied in various rolling mills. Lignum vitae seems to be the most satisfactory wood for the purpose. Comparative tests with bronze bearings, plain wood bearings and the new chambered bearings show a greatly increased rolling tonnage in the case of the last mentioned type. GN(12c)

Forging (12d)

Higher Quality Locomotive Forgings. W. J. KNIGHT. *Railroad Herald*, Vol. 34, Feb. 1930, pages 27–29.

A discussion of the factors affecting construction of high-quality locomotive forgings and of steel composition. Considers the method of heat-treating all steels after they have been shaped by forging. (12d)

Manufacture of Bolts & Nuts. E. J. WILEY. *Proceedings Staffordshire Iron & Steel Institute*, Vol. 45, 1929–30, pages 49–59.

Includes discussion. Elementary exposition of British methods of manufacture. The British have to use slow methods for Whitworth head bolts because these contain more metal in the head than can be upset in one blow without buckling. HWG(12d)

Compressed Air for Forge Hammers. *Heat Treating & Forging*, Vol. 16, Aug. 1930, pages 985–988.

Discusses the advantages of air over steam and presents information on various plants using compressed air. MS(12d)

Power Control in Hydraulic Forging. VICTOR TATARINOFF. *Heat Treating & Forging*, Vol. 16, March 1930, pages 321–324.

Discusses certain important factors in obtaining the greatest possible economy of production in a hydraulically operated forging plant. These are reduction of water leakage in hydraulic machinery and piping; reduction of water pressure losses in the pipe-line; proper utilization of pumping plant in close accordance with actual water consumption by presses; and stopping the pumps when no press is working. MS(12d)

On the Hot and Cold Working of Austenitic Nickel Steel and Transformer Iron. (Ueber die Kalt und Warmverformung von austenischem Nickelstahl und Transformereisen.) F. SAUERWALD, F. FLEISCHER, A. FISCHNICH & A. RADEMACHER. *Archiv für Eisenhüttenwesen*, Vol. 3, Nov. 1929, pages 365–368; *Stahl und Eisen*, Vol. 49, Dec. 12, 1929, page 1799.

The capacity of strain hardening and the velocity of recrystallization of an austenitic 25% Ni steel and a 4% Si transformer iron was studied on rapid working at various temperatures. These 2 materials were chosen to study the strain hardening in steels which contain either the α-iron or the γ-iron stable over a wide temperature range. The relation between specific deformation work and temperature was established by determining the Brinell hardness after the specimens had been subjected to quick deformations under a drop hammer. The results show that, in rapid working, strain hardening is apparent in Ni steel for temperatures up to 900–1000° C. Strain hardening no longer appears at these temperatures in the transformer iron. Spontaneous crystallizations during the performance of work appear in the Ni steel between 900° and 1000° C.; in the transformer iron at 1000° C. Both steels show a maximum of the strain hardening in the range of blue brittleness. Furthermore, there exists a temperature range within which the work of displacement does not, or only slightly, decreases with the temperature. This observation in Ni steel must, probably, be related to peculiarities of the temperature dependence of the hardness of pure Ni which, evidently has a blue brittleness range, also. GN(12d)

Shearing & Punching (12e)

Determination of the Capacity of a Shear of a Merchant Mill. (Ermittlung der Leistung einer Teilschere an einer Feineisenstrasse.) H. ZIMMER. *Stahl und Eisen*, Vol. 5, Dec. 11, 1930, pages 1751–1752.

The capacity of a shear of a merchant mill was investigated to determine to what extent the shear may decrease the production capacity of the mill. Diagrams are shown to illustrate the findings. GN(12e)

Metal Working in Power Presses. E. V. CRANE (E. W. Bliss Co.). *Preprint, American Institute of Mining and Metallurgical Engineers*, 1931, 31 pages.

The operations in a punch-press may be grouped according to whether the metal is sheared, bent, drawn or squeezed. These operations are analyzed in detail. The deformation in presses is discussed in relation to the tensile values. JLG(12e)

Extruding (12f)

Extrusion of Bismuth Wire. J. G. THOMPSON. *Metals & Alloys*, Vol. 1, Nov. 1930, pages 826–827.

Bismuth wire is produced in single pieces up to 20 ft. in length by means of an extrusion press which is described in detail. 3 dies with orifices, respectively, 0.012, 0.025, 0.031 in. in diameter were used and successful operation was obtained only when the press was charged with a single sound piece of bismuth. The pressure necessary for extrusion depends upon the dimensions of the die and upon the temperature. The properties of the wire vary with the diameter and the conditions of extrusion. In general the wire is flexible enough and has enough tensile strength to be formed in a coil of comparatively small radius but will break if bent too rapidly or at too acute an angle. ESC(12f)

Machining (12g)

How to Drill High-Manganese Steel. *Machinery*, Vol. 36, Aug. 1930, pages 978–979.

High-manganese steel generally contains 10–15% Mn, 1–1.5% C and small amounts of Si, P and S. These steels can be drilled with "Hercules Major" drills made by Whitman & Barnes, Inc., Detroit, Mich. For best results, the drilling machine must have positive feed and powerful drive. Drill point should be warmed before using. In some cases, the Mn steel should be heated to 400° or 500° F. The peripheral speed of the drill should be 12–15 ft./min.; feed between 0.003 and 0.010 in./rev. Do not use coolant or lubricant. A continuous cut should be made. Deep holes should sometimes be drilled in 2 operations, allowing the metal to cool between cuts. RHP(12g)

Carboloy Tools at the White Motor Plant. *Machinery*, Vol. 36, Aug. 1930, pages 980–982.

Carboloy has been used as a tool in about 300 different operations by the White Motor Co. Materials cut are cast Fe, malleable Fe, gun Fe, aluminum bronze, brass, Al and in a few cases steel. Accurate check is kept of each tool. Production increasing in machining cast Fe has been from 30 to 40%; for steel drums 17%. In cylinder bores the best tools formerly made 8 cuts before sharpening, with carboloy 1000. Total life of former tools 240 facings, carboloy 30,000. Total former tool cutting cost was $981.50 as against $37.50 at present. Former tool cost per set $18.00 is now $227.00 for carboloy, yet annual tool cost is $750.00 less than before due to longer life of carboloy. Cutting speeds have been increased. Gives directions for use of carboloy tools. Results obtained have exceeded expectations. RHP(12g)

Making Little Ones Out of Big Ones. *American Machinist*, Vol. 73, Sept. 25, 1930, pages 499–502.

A symposium on methods of breaking up long, heavy chips incident to the use of tungsten-carbide cutting tools. Brief articles regarding this question are submitted by Charles R. Whitehouse, Arthur Bramwell, Martin H. Ball, James R. Cornelius and Roger D. Prosser. Various methods are suggested, including method of grinding tool to curl chip, and an idle revolution or part of one for each cutting revolution. RHP(12g)

DEFECTS (13)

Chipping of Square Billets by Machine. *Rolling Mill Journal*, Vol. 4 July 1930, pages 361–362.

Billet peeling machine of the planer type has recently been designed. Incorporates unusual sensitivity and ease of control which permits the cutting tool to follow the camber as well as any crack in the billet in any direction with almost the same ease as if the cutting tool were directly in the operator's hand. It has peeled billets 6 in. square and 10 ft. 6 in. long in 12 min., including setting-up and removing time. MS(13)

A Sand Cast Test Bar for Specification Purposes for Aluminum Alloy Castings. S. L. ARCHBUTT (National Physical Laboratory, England). *First Communications of the New International Association for the Testing of Materials.* Group A. Zurich, 1930, pages 273–276.

Suggests casting a separate test bar 1" diameter, 7 or 8" long in a 2" diameter sand-lined steel tube with 1/2" sand lining (green or dry) standing on a sand base, inclined 30° to the vertical and top-poured. It has so far been tested on Y-alloy only. This is claimed to show the tendency of the metal toward porosity and pin-holing, better than other test bars. HWG(13)

CHEMICAL ANALYSIS (14)

Improved Technic for the Qualitative Micro-Analysis of the Silver Group. A. BENEDETTI-PICHLER. *Industrial & Engineering Chemistry, Analytical Edition*, Vol. 2, July 15, 1930, pages 309–311.

Presented before the Atlanta Meeting of the American Chemical Society, Division of Physical and Inorganic Chemistry, April 1930. The method is an attempt to improve Schoorl's method by working with capillary tubes and centrifuge cones. The experimental procedures are outlined and some of the micro-tubes and other devices illustrated. MEH(14)

Spectroscopic Analysis of Metals. D. M. SMITH. *Bulletin British Nonferrous Metals Research Association*, No. 28, 1930, pages 7–14.

A lecture discussing the production of a spectrum and the results which can be obtained by spectroscopic examination of metals with particular reference to some recent developments. (14)

Evaluation of Stibnite. II—Determination of Antimony. WALLACE M. MCNABB & E. G. WAGNER. *Industrial & Engineering Chemistry, Analytical Edition*, Vol. 2, July 15, 1930, pages 251–256.

The titrations of trivalent antimony by bromate, iodine, or permanganate, under properly adjusted conditions, yield practically identical results. In presence of ferrous iron the titration of trivalent antimony with iodine in a solution buffered with bicarbonate, is affected by a negative error. A method for determining iron present as impurity in stibnite is described. The Frankford Arsenal method for determination of antimony in stibnite was found to yield results about 0.5% too low. The evolution procedure has been extended to include both the iodometric determination of sulphide sulphur and the titration of antimony with permanganate, analysis for both being made on a single sample. 44 references are cited. MEH(14)

Use of Tantalum as Cathode for the Electrodeposition of Copper. B. MEARS & P. R. PINE. *Industrial & Engineering Chemistry, Analytical Edition*, Vol. 2, July 15, 1930, page 298.

The authors use a 1:1 aqueous solution of ammonia (sp. gr. 0.90) made 10% with respect to trichloroacetic acid. Ten consecutive depositions of copper were made, stripping each time with the above solution. Each deposition was practically perfect, being smooth, highly adherent and of excellent color. The electrode showed no deterioration, and after the tenth stripping was of high metallic luster, entirely free from oxide and showed no tendency toward brittleness. Loss in weight per stripping amounted to one part in 150,000. Time for each stripping was less than 5 minutes. MEH(14)

A Magnetic Method for Determining Carbon in Steel and Its Application in Deoxidation Processes. (En Magnetisk Metod för Kolhaltsbestämning hos stal, och dess Annvandning vid Färskningsprocesserna.) C. J. GUNNAR MALMBERG. *Jernkontorets Annaler*, Vol. 114, Oct. 1930, pages 508–545; *Elektrotechnische Zeitschrift*, Vol. 52, Jan. 15, 1931, page 80.

The method depends on submitting a test piece to a variable magnetic field, and measuring the induction. Thus a sample submitted to field strength H_1 then to a lower field strength H_2 will after several repetitions show an induction B_1 and B_2 which differ by an amount characteristic of the C content. A ballistic galvanometer is used for measuring the induction, and the whole circuit is built into a compact apparatus known as a carbometer, on which the readings indicate the difference $B_1 - B_2$. The test pieces, fitting into the magnetic circuit, are ingots of 12.90 ± .03 mm. radius poured from the steel bath. Since the diameter of the ingot is likely to vary with the composition it is recommended that a series of ingots of known composition be poured and used as standards. The texture of the ingots on breakage has no effect on the readings, and the C is uniformly distributed through the sample. The value of the carbometer reading is independent of the troostite, but ferrite and cementite, which form under 0.20% and above 1.20% C. respectively, raise the carbometer value. The presence of Al has no influence on the reading for 0.60% C. but is lower for lower Al contents and higher for higher Al. Silica and Cr increase the readings; W and Mo lower them; while Mn and Ni behave somewhat as Al. O, H, and N produce marked irregularities. HCD + Ha(14)

Rapid Method for the Determination of Selenium. (Schnellmethode zur Bestimmung von Selen.) E. BENESCH & E. ERDHEIM. *Chemiker Zeitung*, Vol. 54, Dec. 10, 1930, page 954.

A solution containing 0.1 to 0.15 g. Se and 5 cc. conc. HCl is treated with 30 g. hydrazine hydrochloride or hydrazine sulphate and boiled. After settling for 1/2 hour Se changes from red to black modification. The precipitate is filtered through a weighed paper, carefully washed and dried. If the sample is in form of a powder, it is heated in a nickel crucible with 3 g. Fe_2O_3, 3 g. $KClO_4$ and 4 g. $NaHCO_3$ until it sinters slightly. Overheating must be avoided. The residue is washed into a beaker and the analysis continued as above. The expensive hydrazine can be recovered from the filtrates after standing and recrystallization. CEM(14)

A Method for the Separation of Lead and Bismuth. (Über ein Verfahren für die Trennung von Blei und Wismut.) H. BLUMENTHAL. *Mitteilungen der deutschen Materialprüfungsanstalten*, Sonderheft 13, 1930, pages 140–142.

See *Metals & Alloys*, Vol. 1, March 1930, page 431. (14)

Determination of Lithium. M. H. BROWN & J. H. REEDY. *Industrial & Engineering Chemistry, Analytical Edition*, July 15, 1930, pages 304–306.

Sodium and potassium chlorides are insoluble in acetone, while lithium chloride is very soluble. This difference is made the basis of separation of lithium from sodium and potassium. Details of the procedure are given. MEH(14)

Potentiometric Titrations. A Review and a Report of Progress. N. HOWELL FURMAN. *Industrial & Engineering Chemistry, Analytical Edition*, Vol. 2, July 15, 1930, pages 213–224.

This review includes a classified bibliography of potentiometric titration methods, and applies to many metals. Author classification is also given, 227 references being included. MEH(14)

The Quantitative Analysis of Steels by Spectrum Analysis. F. TWYMAN & A. A. FITCH. *Engineering*, Vol. 130, Nov. 14, 1930, pages 635–636.

Condensed from paper read before the Iron & Steel Institute, Prague, Sept. 15, 1930. *Metals & Alloys*, Vol. 2, Jan. 1931, page 12. LFM(14)

The Analysis of Residues of Alloys Steels by Chlorination. (Lässt sich die Rückstandsanalyse durch Chloraufschluss auf legierte Stahlsorten anwenden.) R. WASMUHT. *Archiv für Eisenhüttenwesen*, Vol. 4, Sept. 1930, pages 155–159; *Stahl und Eisen*, Vol. 50, Oct. 2, 1930, pages 1407–1408.

In a previous investigation by Oberhoffer and Wasmuht (*Archiv für Eisenhüttenwesen*, Vol. 2, 1929, pages 829–842), a method was described to determine, by chlorination, oxides which are found in the residues of steels dissolved in acid. This investigation refers to the determination of chromium oxide, tungsten oxide, molybdenum oxide, nickel oxide and cobalt oxide by the same method. The method can be used only in case the carbides present are already completely disintegrated at the temperatures used in chlorination. The results are that the determination of oxygen which is combined with W, Mo, Ni and Co is not possible, since chlorine gas attacks these oxides at temperatures at which the attack of the gas on the carbides present is not yet completed. Only the determination of chromium oxide seems possible when a chlorination temperature of 500° C. is applied. In order to obtain reliable results the same time of chlorination must be used. The method was used to determine the content of chromium oxide of various ball bearing steels of English and Swedish origin which, though similar in composition, showed remarkable differences in quality. This difference could be traced back by the chlorination method to an essential difference in the amount of chromium oxides present. For an abstract of the earlier article see *Metals & Alloys*, Vol. 1, Sept. 1929, page 120. GN(14)

Determination of Metallic Iron in Ores. (Über die Bestimmung des metallischen Eisens in Erzen.) W. ACKERMANN. *Chemiker Zeitung*, Vol. 55, Jan. 14, 1931, pages 30–31.

Contains 4 references. The method investigated depends on the reaction $Fe + HgCl_2 = Hg + FeCl_2$, by which metallic iron can be separated from some of its compounds. After filtering and adding Reinhardt solution, Fe is titrated with $KMnO_4$. This method gives good results when Fe is mixed with oxides, but gives low results if mixed with limonite and high results if mixed with FeS, ferro-phosphorus or Fe_3C. CEM(14)

Short Method for Complete Analysis of Magnesium-Aluminum Alloys. S. S. SINGER. *Industrial & Engineering Chemistry, Analytical Edition*, Vol. 2, July 15, 1930, page 288.

The analysis of aluminum alloys containing magnesium presents difficulties owing to the fact that Fe and Al, which form phosphates insoluble in ammonia, must be removed before the Mg can be determined. The proposed shorter but still accurate scheme is based upon the fact that Fe and Al will not be precipitated by sodium ammonium phosphate in the presence of tartaric acid, while the Mg will be precipitated quantitatively. Chilling is resorted to in order to speed up the precipitation. Details of the method are given. MEH(14)

HISTORICAL & BIOGRAPHICAL (15)

Aluminum Alloy Progress. *Iron Age*, Vol. 126, Nov. 20, 1930, page 1455.

Investigation of Al alloys was first started by Deville about 1855. Al-Si alloys were investigated at a very early date but little use resulted until later. Al-Mg alloys were used on a small scale between 1890 and 1900. Beginning of present strong alloy industry and heat treatment took place about 1907–1911. From 1919 to present time intensive alloy developments have been conducted by the Aluminum Co. of America. Cites several very recent developments. VSP(15)

ECONOMIC (16)

The Extension of Canadian Platinum Extraction. (Der Ausbau der kanadischen Platingewinnung.) *Deutsche Goldschmiede-Zeitung*, Vol. 33, Dec. 13, 1930, page 590

Discussion of the large quantity of Pt now being obtained in Canada and its effect on price. JLG(16)

Union Miniere—Largest of the Copper Producers. *Engineering & Mining Journal*, Vol. 130, Nov. 24, 1930, page 506.

An abridged translation of the Company's booklet "Le Katanga Pays du Cuivre" shows the Union Miniere to be the world's greatest Cu mine. The operations are outlined. WHB(16)

The Tin, Radium and Cobalt Interests of the Union Miniere du Haut Katanga. *Metal Industry*, London, Vol. 37, Sept. 26, 1930, pages 289–291.

Translation of portions of a brochure in French by the Union Miniere de Haut Katanga dealing with the tin, radium and cobalt mines of the company. VSP(16)

Sees Potential Steel Market of Over 161,000,000 Tons. *Iron Trade Review*, Vol. 86, June 26, 1930, pages 43–45.

Trade Research Division of the National Association of Flat Rolled Steel Manufacturers estimates a total annual possible consumption of about 8,180,000 tons in the fields covering office furniture, household furniture and equipment, automobile wheels and bodies, pressed and welded steel parts shelving and bins, steel lath, steel buildings, building materials, electric light and telephone poles, and farm markets. Total possible consumption is estimated to be 161,113,340 tons. MS(16)

Magnesium and Its Compounds in 1929. PAUL M. TYLER. *Mineral Resources of the United States*, 1929, Part II, pages 119–138, *United States Bureau of Mines*, Nov. 20, 1930.

In 1929, domestic output of metallic Mg was 665 short tons, an increase over 1928 of 155%. The entire output comes from the Dow Chemical Co., who make it from magnesium chloride. Much progress has been made in the development of extrusion, forging and other fabrication methods. Mg wire and ribbon are used largely for degassification of radio tubes. Extruded ribbon is used in various heating appliances; it is wound around the article to be insulated and then subjected to superheated steam which converts the metallic ribbon into an insulating film of oxide. AHE(16)

The Iron Industry of China. (Chinas Eisenindustrie.) KARL WENDT. *Stahl und Eisen*, Vol. 51, Jan. 1, 1931, pages 1–8.

The article deals with the historical development of the Chinese iron industry, surveys the deposits of ores and coal and describes all Chinese iron and steel manufacturing companies. The raw materials for a large scale steel production are available, the transportation system must be improved, however, before a successful iron industry can be built up. GN(16)

Research and Promotion Will Aid Castings Industry. ROGER L. WENSLEY (G. M. Basford Co.). *Steel*, Vol. 87, July 10, 1930, pages 50–51, 60.

From a paper read before Steel Founders' Society of America. MS(16)

The Economic Position of the Siegerland Iron Mining Industry Compared with the Iron Mining Industry Abroad. (Die Wirtschaftlichkeit des Siegerländer Eisenerzbergbaues im Vergleich zum ausländischen Eisenerzbergbau.) R. SCHNEIDER. *Stahl und Eisen*, Vol. 50, Feb. 20, 1930, pages 229–233.

The stagnation of the iron ore mining industry in the Siegerland is attributed to the burdens imposed on the industry by ideas of social welfare. GN(16)

MANUFACTURERS' LITERATURE REVIEWS

In this department we each month list the catalogs and other printed matter issued by manufacturers. Unless otherwise noted, any of the items listed may be secured free upon application to the issuing firm. Manufacturers who have not yet sent in their printed matter are invited to do so.

501 **Smithsteel Coat of Mail** is a modern armoring, needed where traffic and load conditions create extreme demands for resistance to wear and shock. Imbedded in the flooring material, with rings of steel exposed flush with the floor surface, it also functions as a reinforcement throughout the entire upper strata of the material. A leaflet describing it can be obtained from the A. O. Smith Corporation, Milwaukee, Wisconsin.

502 **Anodes.**—Udylite cadmium anodes have been drastically reduced in price although the quality is as high as ever. The Udylite process gives supreme rust protection and a beautiful silver-like finish. A broadside announcing the price reduction has been sent out by the Udylite Process Company, 30 East 42nd St., New York, N. Y.

503 **Automatic Control Instruments.**—Catalog No. 8008 of the Brown Instrument Co., Wayne and Roberts Aves., Philadelphia, Pa., lists their various recording, signaling, indicating, and alarm controllers for temperature, pressure, flow, etc. The catalog is fully illustrated and each instrument is discussed in a short paragraph.

504 **Copper and Brass in Construction.**—The April 15th issue of the Bulletin of the Copper & Brass Research Association, 25 Broadway, New York, N. Y., is devoted to the use of copper and brass in the construction of new buildings on the pacific coast. It also contains a short article describing an ingenious method for making patterns for bronze pieces from living flowers.

505 **Heat Treating.**—The Vincent Steel Process Co., 2434 Bellevue Ave., Detroit, Mich., has sent out a leaflet telling about their heat treating process and the advantage of having steel heat treated at a plant where it is under the personal supervision of competent workmen.

506 **Calcium Molybdate.**—An interesting book with this title is published by the Climax Molybdenum Co., 295 Madison Ave., New York, N. Y. It discusses this salt very thoroughly, giving its use in alloying iron and steel with molybdenum and the amounts necessary in the various steel-making processes. A brief discussion of molybdic oxide is appended.

507 **Heat Treating Furnaces.**—Catalog 309 sent out by the W. S. Rockwell Co., 50 Church St., New York, N. Y., describes their continuous heat-treating furnaces of the pusher type. These can be obtained either electric or fuel-fired. It includes several pages of designs developed to meet different requirements for heating, cooling and handling. Catalog 294 is a reprint of a paper "Economics of Industrial Heating" which was presented at the New England Industrial Electric Heating Conference in 1929.

508 **Foundry Equipment.**—The March and April issues of "Better Methods" which is published monthly by the Beardsley & Piper Co., 2541 N. Keeler Ave., Chicago, Ill., contain articles describing installations of their sandslingers in factories. In the April issue there is also an interesting article entitled "Merchandising Foundry Products."

509 **Metal Spraying Process.**—This booklet by the Metal Spray Engineering Co., 3501 Croton Ave., Cleveland, Ohio, explains their method of spraying metals, gives a list of metals that can be successfully treated this way and suggests a number of objects which can be advantageously lined or coated by spraying.

510 **Arc Welding.**—An interesting booklet on this subject has been prepared by the Westinghouse Electric & Manufacturing Co., East Pittsburgh, Pa. It contains an article on a few applications of Automatic Arc Welding which is quite complete, illustrating the equipment and giving costs. This is quite complete, illustrating the equipment and giving costs. This is their bulletin No. 14.

511 **Alloy Steel Castings.**—The Lebanon Steel Foundry, Lebanon, Pa, has sent out a leaflet showing the use of their stainless steel castings on the "Enterprise." Modern equipment and exacting laboratory research assure the high quality, fine finish and soundness of these castings.

512 **The Laboratory.**—A new metallographic polisher is described in the Vol. 4, No. 2 issue of this publication of the Fisher Scientific Company, 711 Forbes St., Pittsburgh, Pa. There is also an article discussing the latest developments in fractional distillation and apparatus designed by Dr. K. C. D. Hickman of the Research Laboratories of the Eastman Kodak Company.

513 **Drawing-Oven.**—Leaflet GEA-785B of the General Electric Company, Schenectady, N. Y., describes their type AD Air Drawing-Oven for drawing carbon steel at temperatures up to 750°. A table showing the sizes of the different capacity ovens is given and several charts illustrating radiation losses and time and power required for various loads. Another leaflet of theirs describes their various heating devices such as soldering irons, immersion heaters, glue pots, etc.

514 **Furnace Regulators.**—Bulletin No. 840 of the Leeds & Northrup Co., 4901 Stenton Ave., Philadelphia, Pa., is devoted to their automatic temperature control for blast furnaces. By using these regulators the blast pressure is smoother, the tonnage of the furnace is raised, there is less loss of flue dust and the furnace operates more efficiently. In addition to these advantages there is a remarkable saving in labor. The bulletin is fully illustrated.

515 **Electrically Heated Industrial Equipment.**—Electrically heated platens are discussed in leaflet TB-24 of the Harold E. Trent Co., 439 N. 12th St., Philadelphia, Pa. It also includes a list of other Trent products.

516 **Nickel Cast Iron News.**—The first installment of "Nickel and Nickel-Chromium Cast Iron" by Paul D. Merica appears in the April 1931 issue of this publication of the International Nickel Co., 67 Wall St., New York, N. Y. It also includes number six of the Intimate Chats on Metallography.

517 **Fahralloy.**—This is a heat, corrosion and abrasion resistant alloy which, in certain of its series, is made to completely resist the destructive effects of solutions of nitric and acetic acids and silver nitrate. This alloy was used for pipe in the Daily News Building in New York as described in a folder sent out by the Southern Manganese Division of the American Manganese Steel Co., 6600 Ridge Ave., St. Louis, Mo.

518 **Furnaces.**—One of the most modern heat treating and forging departments in the country is the newly erected division of the Spicer Manufacturing Company. The furnaces used were supplied by the Surface Combustion Company and are described in a folder sent out by them recently. 2375 Dorr St., Toledo, Ohio. They have also issued a bulletin on the installation of their gas-fired oven furnaces at the Delaware Tool Company.

519 **Rust Proofing.**—The April issue of the Udylite News, published by the Udylite Process Co., 30 East 42nd St., New York, N. Y., deals specifically with the various applications of Udylite plating in the aircraft industry, although some household articles are illustrated which are Udylite plated.

520 **Electric Borium.**—The April issue of Fusion Facts by Stoody Co., Whittier, Calif., is given over to a discussion of their Electric Borium. There is some consideration of the cost of applying it and instructions for its use. There are profuse illustrations of several building-up processes using this product.

521 **Metal Melting Furnaces.**—The Campbell-Hausfeld Co., Harrison, Ohio, manufacture all types and sizes of these furnaces from a small one for laboratory use to a barrel type furnace with a capacity of 2000 lbs. The various kinds are illustrated and priced in their catalog 27. Some of their other items such as skimmers, nozzles, strainers, etc., are shown also.

522 **Welding.**—An interesting article on the welding of various alloys is a feature of the April issue of Oxy-Acetylene Tips which is published by the Linde Air Products Co., 30 E. 42nd St., New York, N. Y. Several articles on the repair of apparatus by welding are also of interest. The magazine is fully illustrated.

523 **Flue Gas Temperatures.**—Information furnished by an accurate and reliable pyrometer equipment for measuring flue gas temperatures enables a boiler plant operator to keep the loss of heat in waste gases at a minimum for his particular plant. Bulletin No. 872 issued by the Leeds & Northrup Co., 4901 Stenton Ave., Philadelphia, Pa., illustrates a number of their pyrometers for flue gas with a complete description of each type and its price.

524 **Furnaces.**—Bulletin No. 190 put out by H. O. Swoboda, Inc., 3400 Forbes St., Pittsburgh, Pa., describes their straight line continuous electric furnaces for heat treating strip metal and wire. Bulletin No. 160 is entitled "Electrically heated Large Asphaltum Coating Tanks" and Bulletin No. 170 is "Electrically Heated Compound Melting Tanks."

525 **Non-Ferrous Castings.**—The Development and Research Department of the International Nickel Co., 67 Wall St., New York, N. Y., has recently issued a booklet entitled "The Use of Nickel in Non-Ferrous Castings." In this report the effect of nickel on the properties of brass and bronze is noted. Several useful tables are given showing typical compositions of nickel for various purposes. A list of special alloy compositions containing nickel, with their trade names is convenient for reference.

526 **Belts.**—Four points of superiority are claimed for belts manufactured by the E. F. Houghton & Co., Philadelphia, Pa., in a leaflet recently issued by them. This belt has a tensile strength of 5000 lbs. per square inch, is adaptable to the smoothest surface, regains its shape after being distorted and can be bent double in a vise.

527 **Small Generator Units.**—Small Generator Units and Their Applications, a new 12-page publication identified as Circular 1908, is announced by the Westinghouse Electric & Mfg. Co., East Pittsburgh, Pa. In it are described four different types of generators used where a small amount of electrical energy is necessary, but where no central station supply is available. These generators are discussed first from an apparatus and then from an application standpoint. Fifteen kilowatts is chosen as the limit of the small generator class.

528 **Lead.**—Extensive use has been made of lead for ornamental purposes as described in the May issue of "Lead" which is published by the Lead Industries Association, Graybar Bldg., New York, N. Y. A number of interesting industrial applications are also discussed.

529 **Pyrometer Tubes.**—X-Ray inspection of metal pyrometer tubes insures uniformity of wall thickness and soundness of metal. Every tube manufactured by the Claud S. Gordon Co., 708 W. Madison St., Chicago, Ill., is so inspected before it goes to the stock room. The prices of various sizes of these tubes are given on page 2B of Bulletin 431 which can be obtained as a reprint from the company.

530 **Brackelsberg Rotating Furnace.**—An attractive folder prepared by the Whiting Corporation, Harvey (Chicago Suburb), Ill., describes this new rotating furnace for melting malleable iron, high grade gray iron and special melting problems. It is fired with pulverized coal and is made in $2^1/_2$, 5 or 10 ton sizes, and produces high quality iron of definite analysis.

531 **Nickel Cast Iron.**—Ni-Resist is a special type of alloyed cast iron which is serving many useful purposes in the chemical and allied industries. It has great resistance to many acid and alkaline solutions, it can withstand high temperatures and has unique electrical characteristics. These features are described in detail in Bulletin No. 208 of the International Nickel Company, Inc., 67 Wall St., New York, N. Y.

532 **Dowmetal.**—This is the trade name that identifies the magnesium alloys developed and manufactured by the Dow Chemical Co., Midland, Mich. A small card has been prepared by the company which lists the composition of the different types of these alloys and suggests uses for them. On the reverse side of the card is a table comparing them with other wrought and cast alloys.

533 **Thermo-lectric Babbitt.**—The Thermo-lectric process of making babbitt is a method of graduated temperature control and hydrogenation which combines the various metals into a perfect alloy which has strength, toughness and anti-frictional qualities. A folder discussing this process can be obtained from David H. Smith & Sons, Inc., Foot of 51st St., Brooklyn, N. Y.

CURRENT METALLURGICAL LITERATURE ABSTRACTS OF METALS & ALLOYS

PUBLISHED MONTHLY BY THE CHEMICAL CATALOG COMPANY, INC.

419 Fourth Ave., New York

Editorial and Advertising Offices: 3619 Forbes Street, Pittsburgh, Pa.

Annual Subscriptions: U. S., Possessions, Mexico and Cuba, $3.00; Canada, $3.50; Other Countries, $4.00; Single copies, 40¢.
Copyright, 1931, by The Chemical Catalog Company, Inc. All rights reserved.

Note. The September issue of METALS & ALLOYS will be Vol. 2, No. 3. For purposes of binding and filing, these monthly bulletins may be considered as Vol. 2, No. 2a, 2b, etc

These abstracts are not critical, but merely review developments. The classification number at the end of each abstract will be of assistance in mounting them on filing cards.

Negative print photostats of the original articles abstracted below can be obtained at 35 cents per page, plus 10 cents for mailing first class. The remittance should accompany the order.

Book Reviews are included below and marked by -B-

CONTENTS—JUNE 1931

PATENT SERVICE

Until we resume regular publication in September, the service rendered by the Patent Department of METALS & ALLOYS will be carried on by Mr. W. M. Corse, 810 Eighteenth Street, Washington, D. C. who can supply copies of United States and foreign patents and translations at reasonable costs.

GENERAL (0)

Progress in Metals. L. W. SPRING. *Metal Progress*, Vol. 1, Sept. 1930, pages 40–45.

A brief review of the advances made in the production of metals suited to the modern requirements of high pressure steam generation, petroleum refining, and the chemical industry. The value of "creep" tests is discussed. Need of a material having high strength at 1000° F. and above is expressed. The increasing applications of alloy steels, both of the pearlitic and austenitic types are noted. WHK(0)

Some Important Advances in Composition and Treatment of Metallic Alloys. (Quelques progres importants dan les proprietes et les traitements de alliages metalliques.) LEON GUILLET. *Revue de Metallurgie*, Vol. 27, Sept. 1930, pages 449–466.

A survey of the important advances in metallurgy during the last 5 years. High points are given about silicon structural steels, steels for use at elevated temperatures and high speed steels containing 5% Co. The performance of track equipment up to the present, made of Hadfield steel can be considerably improved by the use of heat treated cast steel containing about 0.30 C, 2.8–4.0% Ni and 0.8–1.5% Cr. It has better machinability, physical properties and better wear. Considerable improvement of the properties of cast iron can be made by alloying it with Ni, Cr and Mo. A description of a series of experiments by Guillet on the influence of Ni and Cr addition and heat treatment on cast iron is given. Si raises the temperature of transformation and diminishes the tendency toward martensitic hardening. Mn (0.20–0.65%) appears to have pronounced influence on hardness after secondary quenching. Ni lowers the transformation temperature below 350°, has a very favorable action on secondary quenching by reducing primary quenching. Cr added to Ni cast iron diminishes the critical speed of quenching and has a strong influence on secondary hardening. Aluminum brasses (76 Cu, 22 Zn, 2 Al) are used for condenser tubing. Ni brasses are considerably improved by this element in physical properties and resistance to corrosion proportionally to the addition of Ni. Ni-Mn brasses can be cast as easily as usual bronzes but have about double their strength and elongation and for many corrosion purposes are among the best known materials. Among aluminum alloys is mentioned a new Rolls-Royce metal (12 Zn, 3 Cu, 6 Mn, 5 Si, 4 Fe) which after quenching and aging gives 42–50 kgs./mm.^{2} tensile, 25 kgs./mm.^{2} elastic limit and 10–15% elongation. Mechanism of hardening is reviewed. It is illustrated by the results of Masing, who after quenching and aging of 5% Be-Cu alloy was able to produce hardness of 412 Brinell. JDG(0)

The Future of the American Iron & Steel Industry. ZAY JEFFRIES. *American Institute Mining & Metallurgical Engineers, Technical Publication* No. 331, 1930; *Heat Treating & Forging*, Vol. 16, July 1930, pages 872–875; *Iron Trade Review*, Vol. 86, Apr. 1930, pages 75–77, 85.

Henry Marion Howe memorial lecture before the American Institute of Mining & Metallurgical Engineers, Feb. 17–20, 1930. MS+JLG(0)

How Can the Different Kinds of Iron and Steel Be Distinguished? (Wie kann man die verschiedenen Eisen- und Stahlsorten erkennen?) H. STOEPEL. *Zeitschrift Feinmechanik und Praezision*, Vol. 35, Nov. 30, 1930, pages 1–2.

A description of methods used to distinguish different materials by simple shop tests: sound test, filing test, cutting test, fracture test, hardness test, grinding test. For the latter, the character of the sparks are described in detail. Ha(0)

Important Developments in the Gray Iron Industry. ARTHUR J. TUSCANY. *Enamelist*, Vol. 7, Aug. 1930, pages 34–36–38.

Brief reference to a few developments in the field. Enumeration of the activities of the Gray Iron Institute, to coördinate the requirements of the user of gray iron castings with the accomplishments of the producer. See *Metals & Alloys*, Vol. 1, Oct. 1930, page 791. W(0)

PROPERTIES OF METALS (1)

Rare Metal Has Many Unique Properties. C. W. BALKE. *Machine Design*, Vol. 2, Dec. 1930, pages 39–42.

Characteristics of tantalum, and design possibilities. Among typical applications discussed are: spinnerets in the rayon industry; hydrochloric acid condensers; chlorine gas cylinders; electrolytic valve elements; filters and screens, etc. Tables of corrosion data and of technical characteristics are given. The Thermal Conductivities of Copper and Nickel and Some Alloys of Nickel. W. C. ELLIS, F. I. MORGAN & G. F. SAGER. *Rensselaer Polytechnic Institute Bulletin*, No. 21, Sept. 1928, 23 pages.

Determinations of the thermal conductivity of 2 grades of nickel and of some nickel alloys gave the following values, which are in good agreement with determinations made by earlier investigators, using different methods:

	Cal./cm./sec./° C.
Nickel (1)	0.147
Nickel (2)	0.168
"Climax" (Ni 30, Fe 70%)	0.0329
"Climax 193" (Ni 28, Fe 68, Cr 2, Mn 1%)	0.0329
"Nichrome" (Ni 80, Cr 20%)	0.0358
"Nichrome" (Nickel 62, Chromium 12, Iron 26%)	0.0325
"Advance" (Ni 45, Cu 55%)	0.0325
"Monel Metal" (Ni 70, Cu 28, Fe 2%)	0.0832 (1)

Melting Point of Pure Tellurium. A. SIMEK & B. STEHLIK. *Collection of Czechoslovak Chemical Communications*, II, No. 5–6, May-June 1930, pages 304–314. 18 references.

Pure metal was obtained by redistilling the precipitated tellurium in vacuum. The method used for determining the melting point of tellurium was essentially that developed in the Geophysical Laboratory of the Carnegie Institution of Washington. This method consists in heating a small charge of the substance in a carefully regulated electric resistance furnace of considerable heat capacity, the temperature of which rises steadily and uniformly per unit of time, say, 2.3 or 4° F. per minute, and is measured separately and alternately with that of the charge every minute or half-minute by means of thermoelements of purest Heraeus platinum and a 10% rhodium-platinum alloy (wires 0.4 mm. thick) which must be carefully homogenized and calibrated before (and when necessary also after) use. Pure tellurium melts in vacuum at 452° C. This melting point is lowered in H and in CO_2 by about 0.15 and 0.2° C., respectively, per 1 atmosphere pressure which can be explained by assuming that both gases dissolve to a considerable extent in fused tellurium at its melting point, the volume absorbed being roughly of the same order of magnitude as the volume of the liquid metal itself. This work was carried on at the physico-chemical Institute of Masarik University, Brno. GTM(1)

PROPERTIES OF FERROUS ALLOYS (3)

High-Test Cupola Malleable Iron Melted with Hematite. (Hochwertiger, mit Hämatit erschmolzener Kupolofen Temperguss.) O. BRAUER. *Zeitschrift für die gesamte Giessereipraxis*, Vol. 51, Jan. 26, 1930, pages 70–72.

Exception is taken to the article by Stotz, in the Jan. 19 issue of this journal, in which he states that hematite has an injurious effect on malleable Fe. The reply of Stotz is appended. (3)

Technological and Metallurgical Fundamentals of High-Test Cast Iron. (Die giessereitechnischen und metallurgischen Grundlagen des hochwertigen Gusseisens.) A. ACHENBACH. *Giesserei*, Vol. 17, Mar. 14, 1930, pages 245–251.

Properties of cast Fe which deviate from those of steel are attributed to the nature of the gray Fe structure. It is, therefore, concluded that means of improving mechanical properties by grain refinement and the prevention of internal defects in casting are necessary. (3)

Gray Iron Possesses Valuable Engineering Properties. *Foundry*, Vol. 58, May 1, 1930, pages 209–212.

Some permanent deformation results on application of even slight stresses to gray cast Fe. In case of steel a quite different condition is met. Gives results of tests conducted on Fe containing 3.25% C, 1.90% Si, 0.25% P, 0.60% Mn and 0.075% S. Results showed total permanent deformation as measured by a dividing engine and by extensometer in 2 in. gage lengths after 25 stress applications:

Series	Dividing Engine Inches	Extensometer Inches
1	0.0020	0.0021
2	0.0028	0.0023
3	0.0028	0.0029
Steel	0.0005	0.0005

Cold working was limited and incipient fracture exists. Results obtained are as follows:

Series	Break Restressed Bar	Break Check Bar	% Difference
1	36,250	34,550	4.69
2	36,010	38,000	5.23
3	21,750	22,500	3.34

Test conducted on untreated bar decreased the stress 55% of ultimate strength. Exact maximum loads above which continued applications of stress would result in failures are determined by creep or flow tests. When slight initial permanent deformation at intermediate loads is objectionable, cast Fe members should be designed heavy. VSP(3)

Properties of High Strength Structural Steels. *Iron Age*, Vol. 126, July 3, 1930, pages 16–18.

From a discussion at the Atlantic City meeting of the American Society for Testing Materials. The conferences centered upon applications of present-day importance of aircraft, bridges, ships, pipe lines and heat corrosion resistant equipment. Attempt was made to draft schedules of wall thicknesses for all sizes of wrought pipe to suit different operating conditions. For high strength structural and ship steel ultimate strength will be raised from 60,000 to 72,000 lbs./in.^{2} A well deoxidized steel of at least 0.20% C and 0.60% Mn can be improved in tensile properties by heat treatment. A 0.30% C and 1.25% Mn steel if normalized possesses a 45,000 lbs. proportional limit. Data on cold drawn bridge wire was presented by Leon S. Moisseiff. The steel was acid open-hearth having a 0.85% C limit. Required physical properties of galvanized wire were: Tensile strength: More than 215,000 lbs./in.^{2} Yield point: more than 144,000 lbs./in.^{2} Elongation in 10 in.: more than 4%. The relative merits of some alloy steels was discussed by Bradley Stoughton and W. E. Harvey. See *Metals & Alloys*, Vol. 1, Nov. 1930, page 843. VSP(3)

Factors in Quality and Strength of Forgings. L. M. JORDAN. *Heat Treating & Forging*, Vol. 16, March 1930, pages 328–330.

Locomotive forgings must be made from steel manufactured by correct methods and cast in properly designed molds. Proper solidification must be allowed for when the ingots are cast, and correct reheating and working into billets must be practiced. Addition of V improves the properties of steel. A low C 2% Ni steel with moderately high Mn content has lately come into prominence. All these steels must be heat treated. Reviews investigations carried out on fatigue phenomena. True cause of fatigue has not yet been definitely established. MS(3)

Recent American Researches on the Physical Properties in Cast Iron. P. BARDENHEUER. *Foundry Trade Journal*, Vol. 43, July 17, 1930, page 38.

Abstract of paper read before the German Foundry Technical Association. Suggestions are made for the classification of cast Fe into 40 classes, according to the C and Si contents. Special considerations to be given to raw materials, cooling speed and shape and size of castings. VSP(3)

Production and Properties of Chill Rolls. (Hartgusswalzen, ihre Erzeugung und Eigenschaften.) W. BREITENBACH. *Giesserei-Zeitung*, Vol. 27, Dec. 15, 1930, pages 655–660.

The melting and casting practice of chill rolls used by various industries (the rubber, paper, ceramic and leather industries) is considered in detail. The cause and remedies of failures are outlined. GN(3)

Growth of Cast Iron. (Wachsen des Eisens.) W. SCHRECK. *Giesserei-Zeitung*, Vol. 27, Jan. 1, 1930, pages 1–3.

Investigations up to the present have shown that growth is greatly increased after passing the critical temperature zone of 750° C. with ordinary Fe. Not only does growth occur but expansion of Fe begins at considerably lower temperatures and with heating at 400°, cast Fe, when quenched, does not return to its original state. (3)

Beryllium-Iron Alloys. (Die Legierungen des Berylliums mit Eisen.) G. KROLL. *Wissenschaftliche Veröffentlichungen aus dem Siemens-Konzern*, Vol. 8, Mar. 9, 1929, pages 220–235; *Aciers Speciaux*, Vol. 4, Sept. 1929, pages 417–422.

Alloys discussed are: Fe-Ni-Be with 5, 15 and 36% Ni and 1% Be; Fe-Ni-Cr-Be with 5, 7, 9 and 8% Ni, 12, 20, 20 and 20% Cr and 1% Be. Tabulated data on their mechanical properties and corrosion resistance. See *Metals & Alloys*, Vol. 1, Feb. 1930, page 383. (3)

Supermal, a Wear-Resisting Metal. *Canadian Mining Journal*, Vol. 52, Jan. 23, 1931, page 106.

The Jeffery Mfg. Co. has marketed a new line of Supermal chains and buckets. Claims for this new metal are: greater resistance to wear, higher tensile strength, and a higher elastic limit than is usual in malleable iron. The qualities compare favorably with like qualities of manganese steel chains, at a cost little more than ordinary malleable chains. WHB(3)

CORROSION, EROSION, OXIDATION, PASSIVITY & PROTECTION OF METALS & ALLOYS (4)

The Influence of Stress Range and Cycle Frequency on Corrosion. D. J. MCADAM, JR. *Proceedings American Society for Testing Materials*, Vol. 30, Pt. 2, 1930, pages 411–447.

Bases of Corrosion. (Grundlagen der Korrosion.) G. MASING. *Zeitschrift für Metallkunde*, Vol. 22, Oct. 1930, pages 321–327. Discussion.

Paper read at the Meeting of the Deutsche Gesellschaft für Metallkunde, March 1930, Berlin, takes the following steps after giving the definition of corrosion: attack by gases and liquids, electrochemical reactions, operating scheme of an electrochemical element, source of electrochemical corrosion, general outline of corrosion attack, prevention by protecting coatings, corrosion of alloys with reference to solid solutions, intermetallic compounds and impurities. EF(4)

Theory of the Protection Effect of the "Schadebinde" against Rusting. (Zur Theorie der Rostschutzwirkung der "Schadebinde.") W. BECK. *Korrosion und Metallschutz*, Vol. 6, October 1930, pages 229–230.

Interpretation from a colloid-chemical standpoint. The remarkable protection against rusting in spite of the completely insufficient insulation is considered and the adaptability of measuring the transition resistance on moist tubes wrapped with a "Schadebinde" in order to determine the corrosion protection is discussed. EF(4)

Corrosion and Protection in Boiler Plants. (Korrosion und Metallschutz im Dampfkesselbetrieb.) R. STUMPER. *Korrosion und Metallschutz*, Vol. 6, Oct. 1930, pages 223–228.

Investigation of a brass condenser tube which failed in service. Internal stresses due to cold working are thought to be the cause which was proven by micro-examination and physical testing in the "as delivered" and annealed state. Defects or corrosion in addition to internal stresses led to failure. See translation in *Metals & Alloys*, Vol. 1, Dec. 1930, pages 895–896. EF(4)

Combating Corrosion of Aircraft Metal Parts. J. E. SULLIVAN. *Aviation*, Vol. 28, Feb. 1, 1930, pages 201–204.

A detailed discussion of preparing metal surfaces, proper coating, inspection and maintenance to insure adequate protection against possible structural failure due to corrosion. A variety of aircraft finishes are discussed. A process for protecting duralumin has been developed by pioneer aircraft manufacturers in coöperation with the Navy Department and the Aluminum Corp. of America. Suggestions are offered for the reduction to a minimum of the evils of corrosion. (4)

Report of American Society for Testing Materials Committee A-10 on Iron-Chromium, Iron Chromium Nickel and Related Alloys. *Proceedings American Society for Testing Materials*, Vol. 30, Part 1, 1930, pages 255–258.

Includes 20 large plates constituting a revision of the data of the 1924 American Society for Testing Materials Symposium on corrosion resistant, heat resistant and electrical resistant alloys. In these tables the trade names, chemical compositions, physical and mechanical properties at room temperature and when available at elevated temperatures, and corrosion resistant properties of many commercial alloys are given. Steels containing Cr or Cr and Ni and other alloys of that class made by the Allegheny Steel Co., Bethlehem Steel Co., Carpenter Steel Co., Republic Steel Corporation, Colonial Steel Co., Crucible Steel Co., Cyclops Steel Co., Duriron Co., Firth-Sterling Steel Co., Latrobe Electric Steel Co., Ludlum Steel Co., Midvale Co., Rustless Iron Corp., Universal Steel Co., Vanadium Alloy Steel Co., Babcock and Wilcox Tube Co., Calorizing Co., Duraloy Co., Electro Alloys Co., General Alloys Co., Michiana Products Co., Michigan Steel Casting Co., Ohio Steel Foundry Co., W. T. Sweet Foundry Co., are included. Electrical resistance alloys, special alloys and aluminum, and other non-ferrous copper alloys as well as some ferrous alloys made by Driver Harris Co., Haynes Stellite Co. Burgess Parr Co., Curtis Bay Copper & Iron Works, International Nickel Co., Westinghouse Elec. & Mfg. Co., Aluminum Co. of America, American Brass Co., American Manganese Bronze Co., American Metal Products Co., Barber Asphalt Co., Chase Brass & Copper Co., Frontier Bronze Co., Riverside Metal Co., Scovill Mfg. Co., National Lead Co., Fansteel Products Co., American Rolling Mill Co., Manganese Steel Forge Co., and Meehanite Metal Corporation are given. This valuable compilation can be purchased separately from the bound volume of the Proceedings. HWG(4)

Methods of Corrosion Testing. (Verfahren der Korrosionsprüfung.) E. K. O. SCHMIDT (Deutsche Versuchsanstalt für Luftfahrt). *Zeitschrift für Metallkunde*, Vol. 22, Oct. 1930, pages 328–333; discussion pages 334–336.

Corrosion testing facilities such as immersion, alternating and spray apparatus, developed by the D. V. L. during the past years with the object of testing the corrodibility of light metal sheets are described and the evaluation of the data obtained is outlined. The results of these methods are reproducible and in fair agreement with practical experience under service conditions. Based on a wealth of experiments, the author urges the determination of ultimate strength (Bruchspannung) and elongation as the best criterion of corrosion attack, since this test yields absolute figures. The deep drawing and alternating bending test also demonstrate the progress of the corrosion attack. However, these testing methods do not permit drawing conclusions in regard to losses in strength and elongation. EF(4)

Can Ferrous Metals Resist Heat and Corrosion Successfully? H. J. FRENCH. *Iron Trade Review*, Vol. 86, Feb. 27, 1930, pages 59–61.

From a paper presented before the American Electrochemical Society, Oct. 1926. MS(4)

American Gas Association, Bureau of Standards Field Study of Long Gas Lines. S. EWING. *American Gas Association Monthly*, Vol. 13, Feb. 1931, pages 70–76.

A gas line from Amarillo, Texas to Denver, Colorado was laid 2 years ago after a careful soil survey to locate corrosive soils. The pipe was coated with a heavy coat of bitumastic "enamel," a light one of "cold paint," or left bare, according to the apparent corrosiveness of the soils. Examination of the pipe after 2 years indicates that the original estimate as to whether the soil would be corrosive or not was 73% correct. It is thought that with the information that has become available within the last 2 years, an estimate made to-day would be 79% right. The coatings failed from distortion, and only the hard enamel has value. The 4 coatings applied are described by trade name, and 2 of these showed no protective value. The electrical resistance of these coatings had fallen to a very low value. Heavy, hard coatings retarded the corrosion of the pipe. Whether the increased life afforded by such coatings is worth the cost is not discussed, a 2 year period doubtless giving insufficient data. HWG(4)

Corrosion Problems in the Viscose Silk Industry. H. R. S. CLOTWORTHY. *Industrial Chemist*, Vol. 6, Nov. 1930, pages 445–447.

The acid and alkaline solutions used in the manufacture of silk cause serious corrosion of plant equipment which results in a weakening of the fiber by the introduction of rust, and a wearing of the fiber on roughened surfaces. There is great need for more resistant materials at many steps in the process. MPB(4)

STRUCTURE OF METALS & ALLOYS (5)
Metallography & Macrography (5a)

The Transformation and the Constitution of High Chromium Steels. TAKEJIRO MURAKAMI, KOJIN OKA & SEIJI NISHIGORI. *Technology Reports of the Tohoku Imperial University*, Vol. 9, Nov. 1930, pages 405–445.

The transformation and the constitution of high Cr steels containing from 10 to 30% of Cr and less than 1.1% of C were thoroughly investigated, by the magnetic, dilatometric and microscopic methods. From the result of the magnetic analysis, isothermal curves for the A_2 point, and the composition ranges in which the lowering of the transformation takes place were determined and the following facts were deduced: (1) The A_2 point descends with increasing Cr content, when the carbon is constant, while it rises with increasing C content, when the Cr content is constant. (2) In the same alloy, the lowered transformation or the Ar″ change increases in magnitude, as the maximum heating temperature rises, or the cooling rate increases, though in high Cr steels in which no γ-phase is formed, no transformation is observable. (3) The Ar″ transformation decreases in magnitude with increasing Cr, when the C content is constant, while the transformation is more readily lowered in medium C steels than in high or low C steels, when the Cr content is constant. By the measurement of the thermal dilatation with slow rates of heating and cooling, the A_3 and A_1 points were determined and the following result was obtained: (1) When the C content is constant, the magnitude of A_3 and A_1 transformations gradually decreases until it vanishes, as the Cr content increases. The temperature of the transformation rises gradually at first and then rapidly, as the Cr content increases. (2) When the Cr content is constant, the A_1 transformation increases in magnitude and its beginning temperature on heating descends, as the C content increases. These relations were also shown with the isothermal lines for the A_1 point. By the microscopic investigation of the quenched specimens from several temperatures, several section diagrams with constant C or Cr content, and isothermal diagrams at various temperatures were constructed, from which the change of constitution with the temperatures and the composition of steels was inferred. A general diagram was also constructed from the diagrams, above referred to, and the process of crystallization for steels belonging to the several fields on the diagram was described. Lastly, the microstructures of principal steels subjected to several heat treatments were illustrated in detail. TM(5a)

On the Equilibrium Diagram of the Iron–Tungsten System. SHUZO TAKEDA. *Technology Reports of the Tohoku Imperial University*, Vol. 9, Nov. 1930, pages 447–461.

By means of dilatometric measurements, microscopic observation and other methods, the equilibrium diagram of the Fe–W system was studied and a revised diagram, as shown in the figure, was proposed. The intermetallic phase ε is a solid solution consisting of Fe_3W_2, which was confirmed by analyzing the residue separated by electrolysis or by acid, from 3 alloys containing 20, 30 and 40% of W. The eutectic point of the ε-phase and the δ-phase lies at 33% W, consisting almost wholly of the δ-phase. The peritectic reaction in which the ε-phase is formed occurs in alloys containing more than 43% W. A loop, within which the γ-phase may be formed was also confirmed by the dilatometric measurements. A probable existence of phase χ which is formed peritectically from the melt and W (or ζ-phase) is inferred from the result of the microscopic investigation, though it is not confirmed by other methods. TN(5a)

Diffusion in Cast Bismuth-Antimony-Alloys. (Diffusion in gegossenen Wismut-Antimonlegierungen.) GEORG MASING & HILDEGIRD OVERLACH. *Wissenschaftliche Veröffentlichungen aus dem Siemenskonzern*, Vol. 9, No. 2, 1930, pages 331–338.

Due to their very great relation and similarity in their lattice structure, alloys of bismuth and antimony form an uninterrupted series of solid solutions, and it has been observed that the exterior shape of cast pieces changed at homogenizing at 300° C.; the outer dimensions increase and in the interior hollow spaces are formed. This phenomenon is explained as accompanying diffusion in solid state. Ha(5a)

Studies upon the Widmanstätten Structure. II.—The Copper-Zinc Alloys and the Copper-Aluminum Alloys. ROBERT F. MEHL & O. T. MARZKE (Naval Research Laboratory). *American Institute of Mining and Metallurgical Engineers, Technical Publication* No. 392, 1931, 32 pages.

In Cu-Zn alloys the α-phase is precipitated from the β-phase as true needles. The needles are precipitated in a direction nearly [111], possibly the [556] direction. All needles of the same family, as judged by etching characteristics, have the same orientation, but it was not possible to determine the exact orientation. Upon slow cooling the γ-phase is precipitated in the form of "stars," but upon reheating quenched specimens polyhedra are formed. The lattice plane in the β-phase defined by the intersecting planes forming the stars is the (110) plane, and the plane enclosing the polyhedra is likewise the (110) plane. Precipitation of β in the precipitated γ polyhedra also formed a Widmanstätten figure. In the Cu–Al system the α-phase appears to be precipitated from the β-phase in needles, and the direction of the needles is probably the same as for the Cu–Zn system. The present work together with earlier work proves that the Widmanstätten figure may be formed of needles, plates or polyhedra, and that the lattice structure of the parent phase is not the only controlling factor. Contains 13 references. JLG(5a)

X-Ray Control in Cold Rolling Steel Sheets and Strip. REPUBLIC RESEARCH CORP. *Iron Age*, Vol. 126, Oct. 30, 1930, pages 1221–1223.

Concluding portion of an article "Physics as an Aid to Metallurgy." Attempts to illustrate the theoretical background for the present-day use of X-ray diffraction methods in the investigations of cold-rolled products. VSP(5b)

The Microscope in Metallurgy. O. W. ELLIS. *Canadian Chemistry & Metallurgy*, Vol. 15, Jan. 1931, pages 25–26, 28.

An address before the Toronto Chemical Association, Oct. 1930. The microscope aids, in the investigation of the constitution of metals and alloys; in the solution of problems of manufacture; and in the control of production. A figure shows a portion of the equilibrium diagram for the alloys of aluminum and magnesium, containing up to 20% magnesium. Applications of the microscope in aiding the manufacture and in the control of metallurgical operations are indicated. WHB(5a)

Transformation Points in Metals. (Ueber die Umwandlungspunkte von Metallen.) A. SCHULZE. *Zeitschrift für Metallkunde*, Vol. 22, June 1930, pages 194–197; Sept. 1930, pages 308–311.

As a further check upon previous work the following metals were investigated in the purest state available: Zn, Bi, Ta and Co. Experiments mainly pertain to measurements of electric conductivity, thermoelectric force and thermal expansion. No allotropy was found in case of Zn and Bi, while transformation points could be established at 225° C. in Ta and at 1128° C. in Co. Includes list of 48 references. Paper was presented before the Deutsche Gesellschaft für Metallkunde, Düsseldorf, 1929. EF(5a)

Constitution of Alloys. (Konstitution der Legierungen.) A. SCHULZE. *Giesserei-Zeitung*, Vol. 27, Feb. 15, 1930, pages 86–97.

A discussion of the physical methods of analysis, electric conductivity and its bearing on the constitution of alloys. Consideration is given to heterogeneous alloys, alloys with solid solutions and 3-dimensional diagrams. The use of electric conductivity for the study of the constitution of alloys has become an important factor in metallography. (5a)

The Relation Between the Hardness and the Particle Size of Iron-Carbide of Carbon Steels. (Die Abhängigkeit der Härte bei Kohlenstoffstählen von der Teilchengrösse des Eisenkarbids.) S. SHIMURA & H. ESSER. *Stahl und Eisen*, Vol. 50, Nov. 27, 1930, pages 1674–1675.

The particle size of iron carbide and its relation to the hardness was studied in quenching and drawing 6 different C steels (C: 0.64%, 0.82%, 0.97%, 1.16%, 1.75%; Mn: 0.08–0.16%; Si: 0.06–0.12%; P: 0.01–0.012%; S: 0.01–0.016%). All steels were heated for 1 hr. to 850° C., quenched in water and drawn then for 10 min., 30 min., 1 hr., 2 hrs., 4 hrs., 6 hrs., 10 hrs., 14 hrs., 20 hrs., 30 hrs., 48 hrs. at 700° to 720° C. All steels were drawn first for 10 min., the hardness and particle size was determined, then drawn for 20 min. more; the hardness and particle size of cementite determined again and so on until all steels have been drawn for 48 hrs. The findings are plotted in diagrams showing that the hardness decreases with increasing size of the cementite until finally, after 48 hrs. drawing, a state is reached where the hardness is practically independent of the C content. In most of the hardness-carbon content curves the eutectoid concentration is indicated by a maximum. The hardness decreases with increasing drawing time and particle size. Within a certain range of the particle size, the hardness decreases only to a limited extent and as soon as this size of the cementite is surpassed, the hardness is independent of the C content. GN(5a)

The Influence of the Transformation on the Thermal Expansion of Steels, Especially in Reference to the Change in the Expansion Coefficient. (Untersuchung des Einflusses der Umwandlung auf die Wärmeausdehnung von Stählen unter besonderer Berücksichtigung der Aenderung der Ausdehnungszahl β.) H. SIEGLERSCHMIDT. *Mitteilungen der deutschen Materialprüfungsanstalten*, Sonderheft 13, 1930, pages 135–139.

Using the quartz dilatometer described by Sieglerschmidt in *Zeitschrift für Instrumentenkunde*, Vol. 45, No. 8, 1925, pages 374–378, thermal expansion curves can be obtained up to 850° C. or even 900° C., which give satisfactory figures for coefficient of expansion as well as show the critical ranges. Data are given for 4 samples as follows:

Mark	C	Si	Mn	P	S	Cu	Ni	Co	Cr	Coefficient ($\times 10^6$) at 100°	300°	500°	700°
A	.71	.36	.62	.014	.032	.18	.20	.03	.04	12.3	14.5	17.0	17.6

An Investigation of Type-Metals. Part 5. On the Microstructure of the Lead-Antimony-Tin Alloys. NOBUTOSHI AOKI, SHOJIRO WAKI & JIRO IKEDA. *Naikaku Insatsu-kyoku Kenkyujo Chosa Hokoku (The Report of the Research Laboratory, Government Printing Bureau, Japan)*, No. 21, Nov. 1930, pages 37–45.

Fifty-five photographs of the ternary alloys of the Pb–Sb–Sn system, chiefly those of the composition range of actual type-metals such as 50–100% Pb, 0–30% Sb and 0–20% Sn, are shown, and the structual constituents of each alloy are elucidated. The equilibrium diagram of this ternary system constructed by the present authors, was ascertained by the microstructures. The primary crystals, α-, β-, γ- and δ-ternary solid solutions, are well etched by a water solution of 5% $FeCl_3$ and 45% HCl and also by an alcohlic solution of 5% HCl. Especially α- and β-crystals are more etchable by the alkaline solutions of $K_3Fe(CN)_6$. In the ternary eutectic structure the closely co-existing α-, β- and δ-solid solutions are well observable. The primarily separated α- and β-solid solutions tend to segregate at the upper part in the melt. TS(5a)

Structure & X-ray Analysis (5b)

The Problem of the Molecular or Atomic Solid Solution of a Metal Compound in a Matrix. (Zur Frage der molekularen oder atomaren festen Lösung einer Metallverbindung im Grundmetall.) G. WASSERMANN. *Mitteilungen der deutschen Materialprüfungsanstalten*, Sonderheft 13, 1930, pages 46–47.

An X-ray Study of the Constitution of Some Copper-Nickel-Aluminum-Manganese Alloys. LYMAN J. WOOD. *Journal American Chemical Society*, Vol. 52, Oct. 1930, pages 3833–3838.

Describes methods and apparatus used, and tabulates results. Both the photomicrographs and X-ray patterns show that these alloys are in the main α-solid solutions. Some evidence for a second constituent is presented but complete identification has not yet been made. VSP(5b)

X-Ray Apparatus. L. G. H. SARSFIELD. *Electrician*, Vol. 106, Jan. 9, 1931, pages 47–8.

Recent developments in the electrical equipment and the new British tubes and instruments are noted. The self-protected hot cathode vacuum type of X-ray tube is in demand, since it dispenses with the heavy and cumbersome tube container. Two notable additions during 1930 to the Philips Metalix range are: (1) the high power medium voltage rotating anode tube in which the anode, a heavy body of copper, forms the rotor of a small induction motor whose stator is a wound ring surrounding the tube; and (2) the large water-cooled tube with a continuous rating of 240,000 volts (peak at 8 m.a.). Each type has a fine focus. (1) is applicable in the medical sphere, and (2) in metal radiography. A recent development is the double focus type tube in which 2 cathode filaments are provided. WHB(5b)

Suppressed Constitutional Changes in Alloys. G. SACHS (The Metallgesellschaft A. G.). *Preprint, American Institute of Mining & Metallurgical Engineers*, 1931, 10 pages.

A method for determining the change in solid solubility by X-ray diffraction methods is described. The determination of the solubility of Cu in Ag by this method is described. The transformations in Au-Cu alloys are discussed in light of recently reported crystal structure studies. Mathematical formulae for the kinetics of transformations in solid alloys are developed. JLG(5b)

PHYSICAL, MECHANICAL & MAGNETIC TESTING (6)

Fatigue Studies of Telephone Cable Sheath Alloys. J. R. TOWNSEND & C. H. GREENALL. *Proceedings American Society for Testing Materials*, Vol. 30, Pt. 2, 1930, pages 395–405.
Includes discussion. See *Metals & Alloys*, Vol. 1, Nov. 1930, page 846. (6)

The Elastic Limit in Shock Tests. (Die Streckgrenze im Schlagversuch.) N. DWIDENKOW & K. JURJEW (Russia). *First Communications of the New International Association for the Testing of Materials.* Group A. Zurich, 1930, pages 231–236. 13 references.
Tensile impact tests are cited to show that the elastic limit of various steels is about 25% higher in impact than in a static test, and the effective elongation is 4 times as great. HWG(6)

Structure Changes During Alternating Stressing. (Gefügeveränderungen beim Dauerbruch.) U. DEHLINGER. *Metallwirtschaft*, Vol. 10, Jan. 9, 1931, pages 26–28.
Contains 8 references. Alternating bend tests were made on cold rolled strips of Ag and Cu and the test pieces were examined by X-rays. The results prove that a cold rolled metal recrystallizes when subjected to alternating stress. The X-ray (Debye) lines, which had been widened, become sharper and definite grains are formed. The magnitude of these changes is a function of the amount of bending necessary to break the test pieces. CEM(6)

Fatigue Testing Machines. (Maschinen für Dauerversuche.) W. DEUTSCH. *Zeitschrift für Metallkunde*, Vol. 22, Feb. 1930, pages 56–61.
This paper, presented at the Session of the Deutscher Verband für die Materialprüfungen der Technik, Oct. 1929, Vienna, reviews the various fatigue testing machines. The different groups are outlined and representative machines or their principles are illustrated. See *Metals & Alloys*, Vol. 1, May 1930, page 524. EF(6)

Cast Iron Testing Methods. (Gusseisen—Prüfungsmethoden.) E. DÜBI (L. von Roll Eisenwerke, Switzerland). *First Communications of the New International Association for the Testing of Materials.* Group A. Zurich, 1930, pages 10–24.
The French suggestion of cutting small test pieces from a casting is not approved. Separately cast test pieces are preferred. From hollow castings made from 5 grades of cast iron and having walls of different thicknesses, specimens were cut and tested. The properties of the specimens from the various locations are compared with those of separately cast specimens in curves and tables, and micrographs are given. HWG(6)

Endurance Properties of Steel in Steam. T. S. FULLER. *Rolling Mill Journal*, Vol. 4, Mar. 1930, page 98.
Abstract of a paper read before the American Institute of Mining & Metallurgical Engineers. See *Metals & Alloys*, Vol. 1, June 1930, page 565. MS(6)

Plasticity of Copper-Zinc Alloys at Elevated Temperatures. ALAN MORRIS (Bridgeport Brass Co.). *American Institute of Mining and Metallurgical Engineers, Technical Publication* No. 390, 1931, 9 pages.
The hot working properties of a series of Cu-Zn alloys was determined by dropping a 50-lb. hammer a distance of 4 ft. onto samples $^1/_2''$ in diameter and $^3/_4''$ long. The samples were heated to temperatures between 600 and 850° C., and their reduction in height determined. The alloys considered the most difficult to hot work, roughly 63 to 80% Cu, had the smallest reduction. Tough-pitch, phosphorized Cu, Muntz metal, machine steel and tool steel were also studied. A mathematical analysis of the resistance offered by the materials to deformation is given. Pb, Sn, Al and Zn were tested at room temperature. The resistance offered to the dynamic pressure by Pb, Sn and Zn is much greater than for a static pressure. For Al the difference is quite small. Contains 3 references. JLG(6)

The Methods of Mechanical Testing of Light Aluminum Alloys. S. NEKRYTY (Kiev Polytechnic Institute, Russia). *First Communications of the New International Association for the Testing of Materials.* Group A. Zurich, 1930, pages 277–292, 9 figures.
General discussion. Claims that test pieces of No. 12 Alloy cast separately give the same results as specimens cut from castings and, on the basis of endurance tests carried only to 25 or 35 millions, and plotted on Cartesian coördinates, to have established that Al alloys have true endurance limits. Claims that the best method of determining corrosion resistance of Al alloys is attack for 15 minutes in 10% HCl. Alleges a relationship between this corrosion test and the endurance properties. Unfortunately, there is no discussion of the papers in this publication, as had there been discussion, all the author's conclusions would doubtless have been challenged. HWG(6)

Tests on the Resistance of Cast Iron to Wear. (Essais de Résistance de la Fonte à l'Usure.) R. SPAZIER (State Railways, Czechoslovakia). *First Communications of the New International Association for the Testing of Materials.* Group A. Zurich, 1930, pages 64–73.
Wear tests were made on an Amsler machine, using a steel disc 4 cm. diameter, 1 cm. thick, and a cast iron specimen 3 cm. wide, 1 cm. thick machined to fit the curve of the disc, and pressed upon it with 25 kg., giving a pressure of 12,000 lbs./in.^{2} It is operated at 188 r.p.m. The wear was determined by loss of weight at 10 minute intervals. The loss at the first 10 minute period, while the specimen is "wearing in" is disregarded, and the average of at least 3 later 10 minute periods taken as the wear figure. Individual figures for the 10 minute periods vary, in one case cited, 600% (from 0.0004 to 0.0025 grams per cm.^{2}). Duplicate tests run for 1 hour instead of 10 minutes (after running in) may vary 200% and more, and show higher wear rates than when the abraded particles are cleaned off for weighing every 10 minutes. Two series of tests are given. In the first, the steel disc was 255 Brinell, 122,000 lbs./in.^{2} tensile, the second 212 Brinell, 99,500 lbs./in.^{2} tensile. The wear loss figures are in grams per cm.^{2} of contact surface per 10 minutes, and are averages of several 10 minute runs after a first 10 minute run.
The lowest wear rate occurs with both high combined carbon and high P. The specimen over 210 Brinell had a much lower wear rate than the softer ones. Wear is not related to tensile strength.

Series	% Composition of Cast Iron: Total C	Graphitic C	Combustion C	P	S	Mn	Brinell	Tensile-Bending-Shock lbs./in.^{2}			Wear Loss Grams/cm.^{2}/10 min.: On Cast Iron Specimen	On Steel Disc

ELECTRO-CHEMISTRY (7)

Electroplating (7a)

Development of Electrodeposition. R. MORDAUNT. *Metallurgia*, Vol. 1, Apr. 1930, pages 251–253.
A general discussion of the applications of electroplating. JLG(7a)

Rhodium Plating Process. *Brass World*, Vol. 27, Mar. 1931, page 61.
Rhodium plating provides a hard non-tarnishable surface with a brilliant white color resembling platinum in appearance. The materials, equipment, operation and solution maintenance are outlined. The plating oufit must be capable of producing 50 amperes at 6 volts or higher. A platinum anode and acid proof wires for suspending the work are used. Application at present is chiefly in the jewelry trade. WHB(7a)

A New Abnormality in the Properties of Aqueous Solutions of Cadmium Salts. ELMER TESCHE & PIERRE J. VAN RYSSELBERGHE. *Preprint* 59-8, *American Electrochemical Society*, April 1931 Meeting, 4 pages.
Electrolysis of aqueous solutions of cadmium iodide yields cathode deposits containing a large amount of adsorbed cadmium iodide. Cadmium bromide behaves in the same way, while cadmium chloride yields normal deposits of pure cadmium. The phenomenon is ascribed to the adsorption of neutral molecules. An explanation for the difference of behavior of the iodide and the bromide on one hand, and of the chloride on the other hand, is suggested. (7a)

Scientific Control of Electroplating Particularly of Nickel and Chrome Plating (Le controle scientifique dans l'industrie des depots electriques, et particulierement des depots de nickel et de chrome). M. BALLAY. *Revue de Metallurgie*, Vol. 27, June 1930, pages 316–325; *Chimie et Industrie*, Vol. 23, Mar. 1930 (Special issue), pages 253–263.
Factors bearing on the electrodeposition of metals are given. Methods of control of composition, pH (colorimetric standards) temperature, current density (a special apparatus for direct determination is described), relative motion of the electrodes and hardness of deposit are given. Three types of baths are known for Ni plating, cold with current density of 0.5–1.0 amp., warm at 30° C. and current density up to 5 amp., and stirring with a current of air and with current density 10–15 amps. The latter has become very popular in France. The composition of the bath is: $NiSO_4 . 7H_2O$ – 450 g.; $NiCl_2 . H_2O$ – 22 g.; H_3BO_3 – 22 g. (per liter) to which is added 1 ml. of $Ni(NO_3)_2$. It is run at pH 4.4–5.5. $Ni(NO_3)_2$ is added because with high current densities an oxidizing agent must be present to prevent the formation of H_2 bubbles. A table showing this effect when $Ni(NO_3)_2$ or $KMnO_4$ is added is given. Conditions necessary for good chromium deposition are taken from the paper by H. E. Haring and W. P. Barrows "Electrodeposition of Chromium from Chromic Acid Baths." (Technological Paper No. 346 of the Bureau of Standards.) Brittleness of the coating is determined by driving a point into the metal and observing the amount of its penetration at the moment of the appearance of the cracks or bending the article and noting the angle at which the cracks appear. Hardness cannot be satisfactorily measured with the present machines. Adherence of the coating can be tested by bending or by a method now under investigation. When a coated article is used as cathode and a few dozen amps./dc.^{2} are passed through it a properly adhering coat remains unaffected while those with deficient adherence peel off. Corrosion resistance can be determined either for the coating itself or for the protection offered by it to the underlying base. In the latter case, feroxyl method is helpful. The determinations of the thickness of coating all involve the knowledge of the area of the sample and the determination of the weight of coating after removal of it from the base. JDG(7a)

The Deposition of Nickel at a Low pH. A. KENNETH GRAHAM. *Metal Industry*, New York, Vol. 29, Mar. 1931, page 118.
Abstract of a paper by C. H. Mougley & W. M. Phillips in the Monthly Review of the American Electroplaters Society, Sept. 1930. Using at high temperatures a nickel solution composed of single nickel salts 32–40 oz., boric acid 3 oz. and nickel chloride 3 oz. and a pH of 1 to 2.5 and current densities well over 100 amps./ft.^{2} very satisfactory deposits are obtained despite an initial tendency to cause pitting. PRK(7a)

Throwing Power of Cyanide Copper Baths. L. C. PAN. *Monthly Review, American Electroplaters' Society*, Vol. 18, Feb. 1931, pages 6–12.
Description of apparatus required; effect of sodium carbonate; effect of sodium thiosulphate; effect of NaOH, effect of NaCl; formulas recommended. MFB(7a)

Calcium Chloride Testing of Electroplated Deposits. H. C. MOUGEY (General Motors Corp.). *Brass World*, Vol. 26, Nov. 1930, pages 301–303.
A paper presented at the 58th general meeting of the American Electro-Chemical Society at Detroit, Sept. 25–27, 1930. See *Metals & Alloys*, Vol. 1, Dec. 1930, page 911. WHB(7a)

The Electro-Deposition of Cobalt-Nickel Alloys. Part II. S. GLASSTONE & J. C. SPEAKMAN. *Transactions Faraday Society*, Vol. 27, Pt. 1, Jan. 1931, pages 29–35.
An investigation of the compositions of the alloys of Co and Ni deposited from well-buffered solutions of definite pH concentration, containing various mixtures of the sulphates of these metals, at a series of current densities and at temperatures of 50° and 90° C. The relative tendency of Co and Ni to deposit was found to be independent of the pH concentration of the electrolyte. The alloys deposited at very low current density contain increasing proportions of Co as the temperature is raised. The proportion is, in general, less than that in the solution for depositions made at 90° C. With increasing current density the proportion of Co in the deposit increases rapidly until a constant maximum Co content, independent of current density, is attained; this maximum decreases with increase of temperature. The influence of Co on the deposition of Ni at 50° C. and 90° C. is very similar to that of Fe at 15° C. and 50° C., respectively. OWE(7a)

Modern Nickel Plating Methods. (Les methodes modernes de nickelage.) MARCEL BALLAY. *Bulletin de la Societe Francais des Electriciens*, Vol. 10, May 1930, pages 545–571.
Description of the contemporary nickel plating practice both in Europe and America. JDG(7a)

METALLIC COATINGS OTHER THAN ELECTROPLATING (8)

International Specifications for Gold-Covered Metals. *Brass World*, Vol. 26, Nov. 1930, pages 289–291.

A report of the "Gold-Covered Articles Commission" before the International Jewelers' Congress in May 1930. It is proposed that Au-covered articles be stamped with a mark indicating the process of manufacture. "Plaque" articles should be distinguished from gilt. French and Swiss systems of marking are discussed. The Commission recommends the addition of representatives from Spain, Sweden, Holland, and the United States of America. WHB(8)

Huge Electric Press is Used in Making Synthetic Wrought Iron. *Electric Journal*, Vol. 28, Jan. 1931, page 26.

The A. M. Byers Co. is making wrought iron mechanically. The puddle balls previously worked by hand are placed in the 900-ton motor-driven press and squeezed into 6000-lb. wrought iron ingots. The main press is driven by a 2100 H.P. reversing motor, built as a double-armature machine to reduce its flywheel effect. A 325 H.P. motor drives the end rams. The motors are fed with direct current by a motor generator set of 4 units—a 1500 H.P. synchronous motor, 1000 kw. and 300 kw. generators for the large and small presses and a 50 kw. exciter. The generators are differentially compounded, the motors cumulatively compounded, the combination causing the press rams to move rapidly early in their stroke, and more slowly as the resistance of the ingot increases. WHB(8)

"Alumetier" Process of Coating Iron and Steel. (Die Alumetierung von Eisen und Stahl.) *Zeitschrift für die gesamte Giessereipraxis*, Vol. 51, Jan. 12, 1930, pages 9–10.

The method described is an especially developed metal-spraying process by which material is first sprayed with an Al layer, then covered with an air tight substance and, finally, heated at a high temperature. Mention is also made of the so-called "fervalizing" which differs from the first process in that to the Al layer is added a coating of other metals in order to prevent the oxidation of the Al. (8)

Report of American Society for Testing Materials Sectional Committee on Zinc Coating of Iron & Steel. *Proceedings American Society for Testing Materials*, Vol. 30, Part 1, 1930, pages 241–243.

See *Metals & Alloys*, Vol. 1, Nov. 1930, page 848. (8)

Hot Zinc Baths for Steel. WALLACE G. IMHOFF (Wallace G. Imhoff Co.) *American Machinist*, Vol. 73, Dec. 18, 1930, pages 962–964.

Standard specification for zinc requires that it contain less than 0.08% iron. Requirements of finished product varies content of bath. The more iron in the bath the heavier will be the coating deposited. New zinc and also tin tend to lighten the coating. Good zinc and aluminum lighten the coating but high iron content and low temperature will give a sticky coating. Tin tends to give a smooth coating. Brittleness may result from too high iron content, too low temperature, or too high metallic additions. RHP(8)

A Pure Zinc Galvanising Process. L. D. WHITEHEAD. *Ironmonger*, Vol. 191, Jan. 25, 1930, pages 64–65.

The advantages of electro-galvanizing over hot galvanizing of wire and strip are pointed out and a new process of electro-galvanizing is described. The important difference between the new and the old process of electro-galvanizing is in the use in the old process of galvanizing baths 60 to 80 ft. long which are costly to construct and difficult to keep liquor-tight. Photomicrographs are included showing the structure of coatings produced by hot galvanizing and by electro-galvanizing from which it is observed that the hot galvanized coating is not uniform in composition. Various methods of proving the efficiency of pure Zn have shown that electro-galvanized wire has a greater resistance to corrosion than hot galvanized products. (8)

Wire Galvanizing Processes. G. K. RYLANDS. *Ironmonger*, Vol. 191 May 3, 1930, pages 67–70.

The author replies to the criticisms of Whitehead (*Ironmonger*, Vol. 191, Jan. 25, 1930, pages 64–65) of the hot galvanizing process and presents the results of comparative tests of hot galvanized (Crapo Process) and electro-galvanized wire in gages 8, 10, 12 and 14 I. S. W. G. (8)

Electro vs. Hot Galvanising. L. D. WHITEHEAD. *Ironmonger*, Vol. 191, May 24, 1930, pages 65–69.

The author replies to the criticisms of Rylands (Ironmonger, Vol. 191, May 3, 1930, pages 67–70) and presents the results of microscopic examination and mechanical tests of electro-galvanized wire and hot galvanized wires of the ordinary British, Crapo and Continental types. (8)

Limitations of Cadmium and Zinc Coatings. Discussion. L. K. WRIGHT. *American Machinist*, Vol. 73, Dec. 11, 1930, pages 919–920.

Discussion on the article by K. A. Eckhardt in *American Machinist*, Vol. 73, page 429. Zinc is cheaper than cadmium. Where lightness is desired cadmium is used. Discusses relative merit of each and thickness of coating necessary. RHP(8)

INDUSTRIAL USES & APPLICATIONS (9)

Large Uses of Steel in Small Ways. Articles 157–169. *Iron Trade Review*, Vol. 86, Jan. 9, 1930, page 31; Jan. 23, 1930, page 34; Feb. 6, 1930, pages 81, 94; Feb. 20, 1930, pages 48, 62; Mar. 6, 1930, pages 89,92; Mar. 20, 1930, page 54; Apr. 3, 1930, page 83; Apr. 17, 1930, page 55; May 1, 1930, page 123; May 15, 1930, page 63; May 29, 1930, pages 58, 61; June 12, 1930, page 63; June 26, 1930, page 47.

Each article deals respectively with messenger call boxes; telephone booths; foot guards; springs; automobile lamps; power lawn mowers; furniture glides; luggage racks; shovels and spades; twist drills and reamers; health scales; windmills; and incinerators. MS(9)

Fabrication of Metal Stove Fronts. E. TONEY (Kawneer Co.). *Metal Stampings*, Vol. 3, April 1930, pages 367–369.

Outlines methods of constructing stove fronts from formed hollow metal sash and bars. Stamped metal ornaments are used. MS(9)

Spiral Springs for Spring-Driven Motors. E. C. WADLOW. *Engineer*, Vol. 150, Oct. 31, 1930, pages 474–476.

Deals with spiral springs such as are used in clocks, recording instruments, phonograph turntables and similar small mechanisms. Discusses torque, running time, motion of spring in barrel, stresses in spiral springs, energy losses in spring barrel, maintenance of constant speed of unwind and mechanical properties of spring material. For phonograph motors it is desirable to use steel of medium tensile strength. Following are properties of typical steel:

Limit of proportionality	88 tons/in.^{2}
Ultimate stress	116 tons/in.^{2}
Elongation in 2 inches	5%
Vicker pyramid hardness no.	560

An average value for modulus of elasticity of spring steel is 28 x 10^6 lbs./in.^{2} over stress range of zero to the yield point of about 85 tons/in.^{2} LFM(9)

JOINING OF METALS & ALLOYS (11)

Welding & Cutting (11c)

Welding-On for Repair Purposes. Effect on the Basis Material. (Auftragsschweissung für Reparaturzwecke. Einfluss auf den Werkstoff der Unterlage.) M. SCHMIT (Gebr. Stork & Co., Holland). *First Communications of the New International Association for the Testing of Materials*. Group A. Zurich, 1930, pages 179–189. 8 references.

Repeated impact, tensile and bending tests show that either gas or electric welding injures the material of boiler plates. (11c)

Questions of Safety in Acetylene-Welding. (Sicherheits technische Fragen beim Azetylenschweissen.) ED. SAUERBREI. *Zeitschrift Verein deutscher Ingenieure*, Vol. 74 Nov. 15, 1930, pages 1591–1595.

This paper discusses the causes of the formation of oxy-hydrogen in and near acetylene plants and the possibilities of ignition of explosive mixtures as well as the frequency of accidents. The entrance of air into the plant while charging, removing of sludge and renewal of water has to be given careful consideration. In many cases, ignition was caused by glowing carbide. About 42% of all accidents was due to backfiring from the flame at the burner. Special attention has to be given the proper sizes of burners and gas producers: often the burners are too large or the acetylene producers are too small. Above all, emphasis is laid on strict adherence to the safety rules which, as statistics show, are violated again and again. Ha(11c)

Automatic Control of the Wire Feed for Automatic Arc-Welding Installations. (Selbsttätige Regelung des Drahtvorschubes bei automatischen Lichtbogenschweissanlagen.) S. SANDELOWSKY. *AEG Mitteilungen*, Vol. 4, Jan. 1931, pages 1–7.

The quality of the welded seam depends on the sensitivity of the regulation of automatic advance of the welding rod. The electrical and mechanical conditions of several arrangements are discussed with regard to their possibilities of calculation and, based on these considerations, several welding-heads are numerically investigated. The sensitivity of the AEG welding head compared to 2 others is found to be 1000 : 10 : 4. Ha(11c)

Gas Cutting Steels and Their Alloys. E. WISS. Part I. *Welding*, Vol. 1, Jan. 1930, pages 154–158.

First of a series of 3 articles. A study of the effects produced on steels and their alloys by gas cutting. The heat effect of the gas cutting process is highest with heavy stock and varies with the composition of the steels; it is higher at the top surface of the cut (since the preheating flames travel over it) and is less at the bottom of the cut (except where the refuse material obstructs the bottom of the kerf, thereby trapping the heat); it is greater on thinner plates that are hand cut than machine cut. Gas cutting refines the grain structure of the face. Gas cut surfaces of Ni steels show a marked in-increase in the Ni content; Ni is more influenced by the heating effect than any other alloy. There are metallographic sections and tables of the properties of the structural steels tested, of the depth to which the influence of gas cutting extends, of the increase in C content of gas cut surfaces, of the changes in content of various alloy elements, of the increase in Ni content of gas cut surface. W(11c)

Progress in Oxy-Acetylene Cutting. (Fortschritte im Autogenschneiden.) A. WIEGAND. *Zeitschrift Verein deutscher Ingenieure*, Vol. 74, Nov. 15, 1930, pages 1585–1590.

In a great number of examples, the progress of oxy-acetylene cutting and welding is illustrated. Cutting burners, cutting apparatus and machines are described and the advantages are pointed out. Ha(11c)

Procedure Control in Aircraft Welding. H. L. WHITTEMORE, JOHN J. CROWE & H. H. MOSS. *Proceedings American Society for Testing Materials*, Vol. 30, Pt. 2, 1930, pages 140–146.

Discussion appended. See *Metals & Alloys*, Vol. 1, Oct. 1930, page 801. (11c)

Welding and Soldering of Nickel and Copper-Nickel Alloys. (Ueber Schweissen und Löten von Nickel und Kupfer-Nickel-Legierungen.) M. WAEHLERT. *Apparatebau*, Vol. 42, Feb. 7, 1930, pages 27–31.

Directions for welding Cu-Ni alloys are given. (11c)

Welding for Repair Purposes. (Auftragsschweissung für Reparaturzwecke.) J. TITSCHER (Bundesbahnhauptwerkstätte, Linz, Austria). *First Communications of the New International Association for the Testing of Materials*. Group A. Zurich, 1930, pages 168–178.

General description of methods used with 17 photos of repair jobs. HWG(11c)

Welding Corrosion-Resistant Steels. E. J. TANGERMAN. *American Machinist*, Vol. 73, Sept. 18, 1930, pages 485–487.

Summary of interviews with several men and other material from several of the larger steel companies. The three methods now in favor are: oxy-acetylene, atomic hydrogen, and electric arc. The latter is usually the cheapest. Despite a high coefficient of expansion good welds are possible in corrosion resistant alloys. Suitable flux is important. Fluxes should have a high solvent power for the oxides formed. Gives instructions for welding several types of steel and special instructions as to the use of each method of welding. RHP(11c)

Some Notes on a "Burned-on" Casting. L. W. BOLTON. *Bulletin British Cast Iron Research Association*, Jan. 1931, pages 342–343.

Bureau Report No. 68 describes physical and microscopic tests of a 1½ inch thick gray iron casting, which had an almost circular hole about 3 inches in diameter filled in by burning on new metal. (11c)

Fabrication of Stainless Sheet Steel and Monel Metal. M. E. OLSEN (Mojonnier Bros.). *Metal Stampings*, Vol. 3, April 1930, pages 347–348.

From paper read before Chicago Section, American Welding Society. See *Metals & Alloys*, Vol. 1, July 1930, page 632. MS(11c)

Calculation of Arc-Welded Seams. (Kalkulation lichtbogengeschweisster Nähte.) H. v. NEUENKIRCHEN. *Schmelzschweissung*, Vol. 9, Dec. 1930, pages 275–276.

The author discusses the consumption of time, electrode material, and electric current for producing a given welded joint. Simple formulas for the calculation of required amount of electrode material to be melted are developed and a few examples illustrate the method. Ha(11c)

Large Engineering Laboratory Is Entirely Arc-Welded. *Electric Journal*, Vol. 28, Jan. 1931, page 40.

The Central Engineering Laboratories building of Westinghouse Elec. & Mfg. Co., at East Pittsburgh is believed to be the largest building built exclusively with arc welding. WHB(11c)

Spot-Welding Machine with Adjustable Pressure. *Electrical World*, Vol. 96, Nov. 22, 1930, pages 978.

The American Transformer Co., Newark, N. J., is manufacturing a spot-welding machine with quick-break contactors and adjustable-pressure mechanism. The welder is known as "Amer Tran" type B-5 and has a semi-automatic device which opens the primary circuit at will and permits the weld to freeze under pressure, preventing arching at the electrodes. The machine may be used for welding Cu and brass, resistance soldering and other applications requiring heavy pressure. The welder is bench-type and operates from a standard 220-volt, 50–60 cycle circuit and is available in 5, 7½ and 10 kva. sizes. WHB(11c)

Republic's New Mill Electric Welds 10 Miles of Pipe in 24 Hours. *Iron Age*, Vol. 126, Aug. 14, 1930, pages 422–424.

Electric welded steel pipes, ranging in diam. from 8⁵/₈ to 16 in. are produced. Preparation of skelp. Quick application and dissipation of heat in welding operation is to prevent abnormal grain growth near the weld. Advantages claimed for welding method. VSP(11c)

Welded Gasometer. (**Geschweisster Gasbehälter.**) *Zeitschrift Verein deutscher Ingenieure*, Vol. 74, Nov. 15, 1930, page 1564.

Contains brief data on a container of 6000 m.³ for the Gas Works of Olten, Switzerland, height 25.7 m., diameter 23 m., weight of structure 183 tons. The stationary parts and roof of the bell are electrically welded. Ha(11c)

Tube and Pipe Welding. *Sheet Metal Industries*, Vol. 4, Dec. 1930, pages 702–703.

Methods of eliminating excessive penetration, which interferes with the free flow of material through the pipe, are taken from a paper by M. R. Meslier which was presented at the International Welding Congress at Zurich. They are as follows; slightly expanding the ends to be joined, forming a socket at one end, fitting a short length of tube over the joint, and fitting a thin sheet steel sleeve inside the joint. The last method is considered best by the writer. AWM(11c)

Electric Welding of Steel Towers. (**Elektrisches Schweissen von Stahlgittermasten.**) *Schmelzschweissung*, Vol. 9, Dec. 1930, pages 283–285.

Describes the construction of towers for a 20,000 volt transmission line which was entirely welded electrically; they could be made in 30% less time than riveted towers. Ha(11c)

New Atomic Welding Machine is Automatic. *Canadian Mining Journal*, Vol. 52, Jan. 16, 1931, page 79.

An atomic hydrogen welding machine has been marketed by the Canadian General Electric Co., Ltd. It is designed for longitudinal seam welding of all kinds and consists of a clamping mechanism for holding the work, an automatic travel carriage, a welding head, and the usual control devices. Alloys containing chromium, aluminum, silicon or manganese can be welded without fluxes and without surface oxidation. WHB(11c)

Welding Torch Extends Use of Electric Arc. *Electrical World*, Vol. 97, Jan. 10, 1931, page 124.

The K. L. Hansen Engineering Co. Inc., Milwaukee, Wis. has developed an arc torch which utilizes the current from a d. c. welding generator, and has electrodes of specially constructed carbons. The positive electrode is given a peculiar channel shape and has a small aluminum core running through its entire length, and the negative electrode has the usual cylindrical shape but one end is tapered to a fairly sharp point. With the two carbons mounted in a suitable holder so that they are inclined at the proper angle, a flame which has been found well adapted to both brazing and welding is projected past the positive electrode. The absence of a blowing effect minimizes the convection heat losses. In brazing copper and copper alloys with the Hansen arc torch the same flux is used as when brazing with the oxyacetylene flame. WHB(11c)

The Fusion Welding of Pressure Vessels. *Engineer*, Vol. 150, Oct. 10, 1930, page 393.

Editorial commenting on "Technical Report for 1929" issued by the British Engine Boiler and Electrical Insurance Company, Ltd. Report discusses progress made in Switzerland in the practice of fusion welding, strength of plate for use in welded pressure vessels, use of atomic hydrogen process of welding, effect of composition and covering of the electrode on the quality of weld obtained, and effect of increasing Mn content of electrode covered with high-grade flux. Large section of report deals with tests made to determine cause of contaminated structures found in welds. LFM(11c)

Unusual Welding Jobs in Ford Fabrication. *American Machinist*, Vol. 73, Oct. 9, 1930, pages 586–588.

Welding methods used for various parts of the Ford motor car. Second of a series of articles on welding in Ford plants. The first appeared in *American Machinist*, Vol. 73, Oct. 2, 1930, pages 537–539. RHP(11c)

Gas-Welding Copper. *American Machinist*, Vol. 73, Nov. 20, 1930, pages 819–820.

Copper in the process of melting and casting absorbs oxygen. Rolling scatters these specks of oxygen throughout where they do not greatly influence fracture. The heat of welding causes the oxide specks to collect along the grain boundaries of the base metal adjacent to the weld which causes a zone of weakness. Completely deoxidized copper will remedy this. The copper should contain 0.05 to 0.15 silicon. A similar copper welding rod may be obtained. Welds of this type have about twice the ultimate strength and elongation as copper containing 0.01 to 0.08% oxygen. RHP(11c)

Welded Tanks. Parts V & VI. *Sheet Metal Industries*, Vol. 4, Oct. 1930, pages 487–488; Dec. 1930, pages 697–698.

Differences in welding wire quality and resulting welds are noted. Observation tests on the wire are described in detail. Simple tests on the physical properties are outlined and the value of first class, dependable welding wire is stressed. AWM(11c)

Welded Pressure Vessels in England. *Welding*, Vol. 1, April 1930, pages 378–382.

Discusses the regulations for fusion welding of pressure vessels issued by the British Boiler and Electrical Insurance Co., Ltd., Manchester, England. Includes a table showing various types of joints and their efficiencies for this work. ACW(11c)

Are Pressure-Welds More Reliable than Fusion Welds? (**Sind Pressschweissungen zuverlässiger als Schmelzschweissungen?**) W. Zimm. *Schmelzschweissung*, Vol. 9, Dec. 1930, pages 269–271.

Tests which have been made with heated pressure-welds indicate that manually made pressure-welds are to a much greater extent dependent on chances and disturbances than fusion welds. The opposite view cannot be maintained. Small plants especially should only rely on and use fusion welding. Several photomicrographs show the reasons for accidents which must be ascribed to an unreliable manual process. Ha(11c)

Comparison of Welded and Riveted Joints. F. P. McKibben (General Electric Company). *First Communications of the New International Association for the Testing of Materials.* Group A. Zurich, 1930, pages 155–162.

Length of welded fillets necessary to give the same strength joints as with rivets of different sizes are worked out by test, and tabulated. HWG(11c)

The Effect of Contamination by Nitrogen on the Structure of Electric Welds. L. W. Schuster. *Engineering*, Vol. 130, Oct. 24, 1930, pages 538–540; *Electrical Review*, Vol. 107, Oct. 24, 1930, pages 710–711.

Condensed from a paper read before the Iron & Steel Institute, Prague, Sept. 15–16, 1930. See *Metals & Alloys*, Vol. 2, Jan. 1931, page 10. LFM+MS(11c)

Electrically Welded Pipe for High-Pressure Water Ducts. (**Elektrische Geschweisste Druckrohrleitung.**) Sonderegger. *Elektrotechnische Zeitschrift*, Vol. 51, Dec. 11, 1930, page 1727.

Description of details in electrically welding a water duct for the Italian hydro-power station Terni-Galleto which has a diameter of 4 m. and a thickness from 10 to 31 mm.; the total height is 190 m. All sections and bends are electrically welded. Ha(11c)

WORKING OF METALS & ALLOYS (12)

Casting & Solidification (12b)

Ingots and Ingot Moulds. Andrew McCance. *Journal West of Scotland Iron & Steel Institute*, Vol. 37, Mar. 1930, pages 101–119.

In dealing with the heat exchanges and the temperature fluctuations, which take place during casting and solidification, and where the specific heats for molten steel and solid mold are different, then the true mean temperature as well as its variation with the temperature of the mold, when plotted, give a rising straight line. The mean temperature may become high enough to produce a local melting of the molds. But in actual practice a layer of air is entrapped between the layer of scale of the ingot surface and the rough surface of the mold. This condition prevents both the molten steel and the mold in coming in intimate contact. When the cooling is too slow the result is a greater heterogeneity of the steel in the ingot. After solidification is complete, the distribution of the heat follows a mathematical expression of heat. The rate of heat absorption by the mold is very rapid during the first few seconds: it falls off quickly, then more slowly to a steady rate, and it is independent of the wall thickness. There are 3 distinct types of crystal growth formed on solidification of an ingot. The first periods exist for the first few seconds when the most rapid heat exchange takes place. The second period results in the formation of columnar crystals, lasting for about 5 minutes from the commencement of the teeming. The last stage is brought about when the rate of heat abstraction falls below 4 cal./sec. the crystals formed now being equiaxial. Slow teeming, by heating the inner surface of the mold and by enabling a thicker ingot skin to form, eliminates the cracking of ingots. Turning now to a consideration of the steel ingot it will be seen from tables No. 1 and No. 2, that the temperature of the outer skin of the ingot in its mold, when there is an air gap present, is approximately constant after the first few minutes and is in the neighborhood of 1100° C.

TABLE 1

Effect of Air Gap in the Ingot and Temperature of Mold

Air Gap mm.	Temp. liquid steel ° C.	Temp. Ingot skin ° C.	Temp. of mold inner surface ° C.	Temp. of mold outer surface ° C.
0	1500	930	930	530
0.10	1500	995	865	512
0.25	1500	1040	820	500
0.50	1500	1044	783	487
1.00	1500	1102	758	480
2.00	1500	1116	744	476

TABLE 2

Effect of Scale on Surface and Air Gap

1 mm. scale assumed on both ingot skin and inner surface of mold.

Air Gap	Temp. steel ° C.	Temp. Ingot scale ° C.	Temp. Mold scale ° C.	Temp. inside mold ° C	Temp. outside mold ° C.	Temp. skin ° C.
0	1500	930	930	863	509	997
0.10	1500	988	872	812	496	1048
0.25	1500	1031	829	774	486	1086
0.50	1500	1065	795	743	478	1118
1.00	1500	1084	773	724	469	1136
2.00	1500	1104	756	710	465	1150

Mathematical treatment of the rate of ingot solidification and the formation of piping show a point not hitherto recognized, that a low temperature of casting will minimize the formation of V segregates by limiting the movement down the central portion of the ingot, and it explains the disappearance of the V segregates at the bottom portion. As the taper is increased there is a rapid decrease in the amount of the piping as shown by the mathematical calculation of the inverted taper mold. GTM(12b)

Cause of Corner Ghost in Steel Ingots. Soji Maita. *Rolling Mill Journal*, Vol. 4, May 1930, pages 245–246.

Abstract of paper read before Iron & Steel Institute, May 1930. See *Metals & Alloys*, Vol. 1, Sept. 1930, page 737. MS(12b)

The Present Status of Casting Silumin. (**Der heutige Stand des Giessens von Silumin.**) *Zeitschrift für die gesamte Giessereipraxis*, Vol. 51, Apr. 6, 1930, pages 57–59; Apr. 13, 1930, pages 62–63.

Silumin, known in America and France as Alpax is an Al alloy containing 13% Si. Its advantages over other Al alloys include lighter weight, better mechanical properties, excellent casting qualities and corrosion resistance. Casting, machining methods and uses of silumin are briefly discussed. (12b)

Casts Unusually Large Nickel-Chrome Retort. *Iron Trade Review*, Vol. 86, March 20, 1930, page 53.

Driver-Harris Co. cast a retort 48 in. in inside diameter, 60 in. deep, with a central chimney 12 in. in diameter. It is part of a special furnace the American Gas Furnace Co. is constructing for the Timken Roller Bearing Co. The retort weighs over 4000 lbs. Special steel flask was made to take the dry sand mold. Exceptionally heavy risers were provided, these having about half the weight of the casting itself. The high Ni-Cr alloy used was poured at 2900° F. MS(12b)

Mold Coatings. (**Anstrichmittel für Gussformen.**) Fritz Beitter. *Stahl und Eisen*, Vol. 5, Dec. 11, 1930, pages 1741–1744.

Report 197 of the Steel Mill Committee of the Verein deutscher Eisenhüttenleute. Includes discussion. The article gives a general discussion of the benefits derived from the application of mold washes, especially the improvement of the surface of the ingots. The advantages and disadvantages of various mold washes, graphite coatings, aluminum coatings and tar-asphalt lacquers are pointed out. Reference is made to the various practices used in applying these coating materials. GN(12b)

Casting of Ingots from Aluminum Alloys. (**Das Giessen von Walzblöcken.**) P. Schwerber. *Giesserei-Zeitung*, Vol. 27, Feb. 1, 1930, pages 61–67.

The material has the strength of cast or forged steel but only ⅓ of the weight. It is believed that these light alloys have all the desired properties of heavier metals with the great advantage of light weight. Methods of melting and casting ingots with special reference to duralumin are described. (12b)

Rolling (12c)

Application of Tapered Roller Bearings to Rolling Mill Service. F. Waldorf (Timken Roller Bearing Co.). *Rolling Mill Journal*, Vol. 4, June 1930, pages 283–290.

Improved methods of making load determinations and the increase of other bearing information have made it possible to develop standardized mountings for several types of mill rolls. Describes some typical standard mountings for roll necks and points out interesting features of some special mountings to show the versatility of such bearings. MS(12c)

Measuring the Steam Consumption of a Rolling Mill. (Dampfverbrauchs-Messungen an einer schweren Walzenstrasse.) HELMUT WEISS. *Stahl und Eisen*, Vol. 50, Dec. 4, 1930, pages 1705–1708. 3 references.

Report 80 of the Rolling Mill Committee of the Verein deutscher Eisenhüttenleute. The steam gage of Hallwachs and Langen, Bensheim, Germany, proved most suitable for the determining of the power consumption of individual passes of a heavy steam-driven rolling mill running on billets, beams, rails and ties. In evaluating the results, conclusions could be drawn as to the improvement of the design of the passes. Furthermore, reliable data could be accumulated on the relation between rolling temperature and power consumption. GN(12c)

Modern Reversing Mill Drives. R. H. WRIGHT. *Iron & Steel Engineer*, Vol. 7, May 1930, pages 210–217.

The author reviews modern practices in applying electric drives to reversing mills and describes the general construction of modern reversing equipment. (12c)

Progress in Manufacturing Rails. (Neuere Fortschritte auf dem Gebiete der Schienenerzeugung.) W. SCHAEFER. *Stahl und Eisen*, Vol. 50, Nov. 6, 1930, pages 1567–1573.

The article considers Coutheaux's rolling method for manufacturing rails with heads with small amounts of segregations and the equipment for improving rails by quenching the surface. The methods of Sandberg, of the plant Neuves Maisons and the method of the Maxhütte are described and illustrated. The first 2 methods improve the wear resistance by obtaining a sorbitic structure of the surface; the latter method obtains the very hard martensitic structure in the surface. Reference is also made to the improvement of rails by using alloy steels and to the fabrication of compound rails, which are made by using 2 types of steel with different tensile properties. In this method, the harder steel is used for the head and the softer for the web and foot. GN(12c)

Effect of Rolling on the Properties of α-Brass. (Einfluss des Walzgrades auf die Eigenschaften von α-Messing.) N. DAVIDENKOW & W. BUGAKOW. *Metallwirtschaft*, Vol. 10, Jan. 2, 1931, pages 1–6.

Contains 15 references. α-brass strips 2 mm. thick, containing 62.95% Cu and 37.03% Zn, were annealed 1 hour at 550° C. and rolled to obtain 0 to 80% reduction in thickness. Tensile strength, yield point, elongation, Brinell hardness, solubility in 25% HNO_3 were determined, and micro and X-ray structure examined. With reductions from 0 to 20% the physical properties increase proportionately. From 20 to 30% they remain constant, in the case of hardness decrease, and above 30% increase again. The curve for solubility is similar to the physical properties. The micro and X-ray structure does not change up to 20% reduction, but from 30% up the crystals become elongated and assume a definite orientation. The critical range between 20 and 30% is explained by the existence of internal residual stresses. After annealing the rolled test pieces at 200° C. the increase in tensile strength is steady without any critical range. The residual stresses were measured by painting one side of 35 mm. long test pieces which had been reduced by rolling and dissolving the outside layer of the other side in HNO_3. The degree of bending due to the residual stresses was measured with a Zeiss optimeter in 0.001 mm. A maximum stress was found with 30% reduction in rolling. CEM(12c)

Piercing Action in the Manufacture of Seamless Tubes. K. SIMONEIT. *Rolling Mill Journal*, Vol. 4, May 1930, pages 247–248; July 1930, pages 375–378.

Translation of the abstract in *Stahl und Eisen*, Vol. 50, Feb. 6, 1930, pages 174–175, of the article by F. Körber and K. Simoneit in Mitteilungen aus dem Kaiser-Wilhelm Institut für Eisenforschung zu Düsseldorf, Vol. 11, pages 353–371. For abstract of this see *Metals & Alloys*, Vol. 1, Sept. 1930, page 737. MS(12c)

Investigation of the Resistance of Deformation of Low Carbon Steel in Hot Rolling between 700 and 1200° C. (Versuche über den Formänderungswiderstand und den Formänderungsverlauf beim Warmwalzen von kohlenstoffarmem Flussstahl im Temperaturbereich von 700° bis 1200° C.) E. SIEBEL & E. FANGMEIER. *Mitteilungen Kaiser Wilhelm Institut für Eisenforschung*, Vol. 12, 1930, Report 159, pages 225–244. See also Resistance to Deformation and Flow of Material in Rolling. (Formänderungswiderstand und Werkstoffluss beim Walzen.) E. SIEBEL. *Stahl und Eisen*, Vol. 50, Dec. 18, 1930, pages 1769–1775.

A low C steel was used for the tests (C: 0.08). In order to study the influence of the rolling temperature, as well as of other conditions on the resistance to deformation, the square bars (30 mm.) were rolled at each temperature with a varying relation between diameter of the roll and height of the bar. This relation is called "Stärkenverhältnisse." The relation amounted, in group 1, to 11.2% (20 to 178 mm.); group 2: 5.6% (10 to 178 mm.); group 3: 2.8% (5 to 178 mm.). Five different reductions were also used in every group. Group 1: 10, 8, 6, 4, 2 mm., corresponding to a reduction of 33%, 28%, 23%, 17% and 9%. Group 2: 10, 8, 6, 4, 2 mm., corresponding to a reduction of 50%, 44%, 37%, 28%, 17%. Group 3: 5, 4, 3, 2, 1 mm., corresponding to a reduction of 50%, 44%, 37%, 28%, 17%. In every group, the rolling temperatures used were 700°, 800°, 900°, 1000°, 1100° and 1200° C. The relation between reduction and resistance to deformation have been established first for the above "Stärkenverhältnisse." The temperature curves of group 1 show a gradual increase. At the low reductions, the velocity of recrystallization seems to be so small that strain hardening occurs even at the highest rolling temperatures used. The 900° C. curve is the steepest, indicating that the resistance to deformation of austenite close to the A_3 point is lower than the resistance to deformation of the α-iron at 800° C. at the high reductions. In groups 2 and 3, no increase of the resistance to deformations is shown at 1000°, 1100° and 1200° C., when the reduction is greater than 30%. Also in these groups, it has been found that the resistance to deformation decreases when the transformation γ-to α-iron takes place. This result is clearly demonstrated when the resistance to deformation is plotted against the temperature. It was furthermore found that the resistance to deformation, under similar conditions, increases with the decreasing "Stärkenverhältnisse." The tests check with static and dynamic deformation tests by M. Hennecke. The results are compared with the results of J. Puppe on the power consumption of blooming mills. A satisfactory agreement is found. The studies on the spread and the slip between the rolls and the material point to an increase of the friction with decreasing temperature. Also these results are in agreement with findings of Puppe on the same subject. GN(12c)

Machining (12g)

General Motors Experience with Tungsten-Carbide Cutting Tools. *Iron Age*, Vol. 126, Oct. 23, 1930, pages 1141–1142, 1201–1202.

Abstract of paper read before the Society of Automotive Engineers at Detroit by W. H. McCoy on the future development of tungsten carbide as a cutting tool. An increased size of tip is advocated to care for heat developed and to prevent temperature rising high enough to cause alloying with metal cut. Machining strains should be removed before applying tungsten carbide. Predicts many different grades of cemented tungsten carbide. See *Metals & Alloys*, Vol. 2, Feb. 1931, page 43. VSP(12g)

Grinding Effects Economies in Dressing High-Speed Tools. *Iron Trade Review*, Vol. 86, May 8, 1930, page 55.

Treadwell Engineering Co., Easton, Pa., has effected marked savings in time and costs by substituting grinding for hand-forging in the dressing of high-speed tools in sizes up to $1^1/_4 \times 2^1/_4$. Larger sizes are difficult to handle. Use Bakelite bond wheels. MS(12g)

Steel Castings and Their Machinability. (Stahlguss und Zerspanbarkeit.) A. WALLICHS & K. KREKELER. *Giesserei*, Vol. 17, Apr. 4, 1930, pages 325–329.

Steel castings of to-day are subjected to thorough tests to determine their machinability. Includes an account of tests carried out by the Aachen machine tool laboratory on standard steel castings and on Ni and Ni-Cr alloys. The influence of melting and of C and Si content are considered. (12g)

Turning, Boring, Facing, Planning Manganese Steel. *Edgar Allen News*, Vol. 9, Sept. 1930, pages 707–708.

Note illustrating the correct use of the proper tools. W(12g)

The Accuracy of Gear Teeth. *Engineer*, Vol. 150, Nov. 7, 1930, page 517.

Discusses tests made at the National Physical Laboratory to determine accuracy of gear wheels produced by different manufacturing methods. Two classes of wheels were tested, those produced by various machining processes and were left soft or hardened after being machined, and those which were machined and hardened and subsequently finished by grinding. A pantograph was used to trace tooth profile on smoked glass. A perfect gear wheel should give record consisting of perfectly parallel equally spaced tooth contours. Conclusions drawn from these tests place gear wheels in following order of descending accuracy: (1) wheels finished by grinding with formed abrasive wheel, (2) wheels finished by grinding with a generating process, (3) wheels cut with specially selected backed-off milling cutters, (4) hobbed wheels, (5) wheels cut with rack or other form of generating cutter. Profile diagrams are reproduced. LFM(12g)

Tungsten Carbide Circular Saws Used on Various Materials. C. M. THOMPSON (Henry Disston & Sons). *Iron Age*, Vol. 125, June 19, 1930, pages 1823–1824.

Taken from paper on "The Application of Tungsten Carbide to Circular Saws" presented at the semi-annual meeting of the American Society of Mechanical Engineers at Detroit. See *Metals & Alloys*, Vol. 1, Sept. 1930, page 737. VSP(12g)

Cutting Pressures and Power Consumption of "Widia" Tools. *Engineer*, Vol. 150, Dec. 26, 1930, pages 699–700.

Compares power consumption figures for cemented tungsten carbide with those obtained by the Cutting Tools Research Committee of the Institution of Mechanical Engineers. Comparison is also made with Ripper and Burley's figures for high-speed steel. Author has plotted curves from figures obtained from various investigators. LFM(12g)

Users of Tungsten Carbide Report Variety of Experiences. FRANK C. SPENCER (Western Electric Co.). *Iron Trade Review*, Vol. 86, June 19, 1930, pages 73–75.

Progress report of the Subcommittee on Tungsten carbide cutting materials of the American Society of Mechanical Engineers. See *Metals & Alloys*, Vol. 1, Nov. 1930, page 852. MS(12g)

Testing the Machinability of Free Cutting Steels. (Die Prüfung der Zerspanbarkeit von Automatenstahl.) A. WALLICHS & H. OPITZ. *Archiv für Eisenhüttenwesen*, Vol. 4, Nov. 1930, pages 251–260; *Stahl und Eisen*, Vol. 50, Dec. 18, 1930, pages 1779–1780.

Twelve different free cutting steels were subjected to a light cutting test to determine whether or not there is a relationship between machinability and tensile strength as it was previously established for structural steels. The cutting capacity, the condition of the machined surface and the formation of the chips were tested. It was found that an interrupted cutting does not impair the cutting properties of the tool. The total cutting time corresponds to the individual cutting times for each individual step. Cutting depth and feed have practically no influence on the produced amount of chips in automatic machining. The smoothness of the machined surface primarily depends on the shape of the chip. The authors observed 3 distinct types of chips: the tear chip, the shear chip and the flow chip. The flow chip is the most favorable as regards cutting capacity of the tool and the smoothness of the surface. Increasing cutting speed gives a smoother surface. The surface condition furthermore depends on the angles of the tool. The above results hold also in cutting threads. In examining the physical properties and the structure of the 11 steels tested, no relation between tensile strength and machinability could be established. GN(12g)

New Tool and Die Steels Give High Production. OWEN K. PARMITER (Firth-Sterling Steel Co.). *Iron Trade Review*, Vol. 86, April 17, 1930, pages 52–54.

Second part of a paper read before the Columbus Chapter of the American Society for Steel Treating, April 8, 1930. For first part, see *Metals & Alloys*, Oct. 1930, page 802. The most recent development in die steels is a Cr-Mo-V steel which has the advantage of ease in machining as compared with the older high Cr-high C die steels, at the same time retaining and improving the outstanding features of the type. Its composition is: 1.40–1.70% C, 0.15–0.30% Si, 0.20–0.40% Mn, 12.00–14.00% Cr, 0.50–1.00 Mo, 1.00–1.50% V. Forging and heating temperatures with resultant hardnesses are as follows:

Operation	Temperature range ° F.	Approximate hardness, Brinell No.
Forging	1700–1900	—
Annealing	1725–1760	200
Preheating	1200–1300	—
Hardening in air	1800–1875*	650
Hardening in oil	1780–1850*	650
Drawing	300–1000	650–600

* Smaller sections should be hardened at lower end of range and larger sections at upper end.

This steel has given excellent service as plug gages, rolls, lathe centers, bushings, and spinning tools, and is particularly valuable in machining non-ferrous metals, such as brass and bronze. In dies, it possesses about 7 times the life and efficiency of C steel and at least double that of high-speed steel. Outlines evolution of high-speed steel. A new super high-speed steel was introduced in 1926. It contains 0.75–0.90% C, 0.20% Si, 0.25% Mn, 17–22% W, 4.50–6.00% Cr, 1.00–2.50% V, 8–15% Co, 0.75–1.50% Mo Special practice is necessary in making this steel. The high-frequency furnace aids in obtaining uniformity. Forging and heat treating temperatures with resultant hardnesses are as follows:

Operation	Temperature range ° F.	Approximate hardness, Brinell No.
Forging	1650–2100	—
Annealing	1600–1700	250
First preheat	1200–1300	—
Second preheat	1700–1800	—
Hardening	2425–2500	650
Drawing	1050–1150	625–675

"Necking-in" Drawn Shells—Discussion. Carl E. Schinman & Chester B. Lord. *American Machinist*, Vol. 73, July 3, 1930, pages 21–22.

Discussion by Mr. Schinman of an article in *American Machinist*, Vol. 72, page 68. Mr. Lord replies and adds to the original article. RHP(12h)

Steels for Cold Pressing. G. R. Bolsover. *Iron & Steel Industry & British Foundryman*, Vol. 4, Dec. 1930, pages 101–102.

Low carbon rimming steels used for deep drawing do not work-harden readily. The tensile strength varies approximately as one third the percentage reduction in steel thickness. When the steel is stretched more than 5% brittleness is encountered on reheating to 200° to 300° C. Age hardening after quenching increases the tensile strength of dead mild steel 67%. For deep drawing purposes stainless steel must be low in carbon and should be quenched from a high temperature. CHL(12h)

Cold Working (12j)

Procedure for Monel Metal and Nickel Tanks and Tank Linings. *Sheet Metal Worker*, Vol. 21, Oct. 31, 1930, pages 657–660.

Practical suggestions are made as to good workmanship in forming, edging, jointing and seaming of Monel metal. GN(12j)

Contribution to the Study of Cold Rolled Steels. (Contribution a l'Etude des Aciers étires á froid.) G. Delbart. *Aciers Speciaux, Métaux et Alliages*, Vol. 5, Nov. 1930, pages 483–508.

Cold rolled steels heat treated to temperatures up to 700° C. were studied. In studying the physical properties of carbon steels at different temperatures, there was noted a fall in tensile strength at a temperature in the neighborhood of 650°–700° C., and the same was true for Brinell hardness. Resistance to corrosion in sulphuric acid is minimum for steel annealed at 700° C. while a favorable effect takes place on magnetic properties at this temperature. GTM(12j)

Cold Work, Physical Properties of Metals. R. L. Templin (Aluminum Company of America). *Heat Treating & Forging*, Vol. 16, Mar. 1930, pages 338–342; condensed in *Metal Stampings*, Vol. 3, Apr. 1930, pages 343–344.

Paper read before the American Institute of Mining and Metallurgical Engineers. See *Metals & Alloys*, Vol. 1, Mar. 1930, page 430. MS(12j)

Cleaning (12k)

Efficiency of a Cleaning Solution. Edw. L. McIlhenny (Cowles Detergent Co.). *Metal Cleaning & Finishing*, Vol. 3, March 1930, pages 210–212.

From paper read before American Ceramic Society, Feb. 15–21, 1930. Outlines action of cleaning solution, gives hints on making the solution and addition of cleaner. Describes an application of the water-break test for determining the exhaustion point of the tank contents. MS(12k)

Scale and Oxide Removed Rapidly by Electrochemical Process. *Iron Age*, Vol. 126, Sept. 25, 1930, pages 860–861.

Describes the Bullard-Dunn Electrolytic process for cleaning metals. Scales, oxides, grease and dirt are removed from metal surfaces by the action of H, electrically generated on surface of metal beneath the scale or oxide. A feature of the process is the protection of the surface from pitting, etching and embrittlement by the H. The acid electrolyte used is made up of 3 oz. of H_2SO_4, 3 oz. of HCl and 3 oz. of NaCl per gallon of water. The alkaline electrolyte is made up of 3 oz. of Na_2CO_3, 4 oz. of $Na_3PO_4 \cdot 12H_2O$ and 9 oz. of NaOH per gallon of H_2O. VSP(12k)

Cleaning of Metal. Pt. I–X. Robert W. Mitchell (Magnus Chemical Co.). *Metal Cleaning & Finishing*, Vol. 2, Jan. 1930, pages 13–18; Feb. 1930, pages 111–114; March 1930, pages 207–210; April 1930, pages 299–304; May 1930, pages 389–394; June 1930, pages 485–488, 493–494, 512; July 1930, pages 585–590, 598; Aug. 1930, pages 673–680, 684, 688; Sept. 1930, pages 759–762, 766; Oct. 1930, pages 839–847.

Includes bibliographies. Discusses the influence of the degree of alkalinity and colloidal action on the efficiency of cleaners; buffering action of cleaning compounds; colloidal action; properties of soaps and other washing colloids; surface tension of common liquids, solutions, and colloidal solutions, and their relation to detergent action; properties of soap solutions and their interfacial tension against oils; adsorbing and emulsifying power of soap solutions; and measurement of hydrogen-ion concentration, buffer action, and detergent action of cleaning solutions. MS(12k)

New Process for Removing Scale from Steel. *Brass World*, Vol. 27, Jan. 1931, page 8.

The Hanson-Van Winkle-Munning Co., Mattewan, N. J., has introduced an electrolytic bright dip. Steel is treated in an acid bath as a cathode and in a second acid bath as anode with a water rinse between. Hydrogen embrittlement is eliminated in all work except highly tempered steel with thin sections, like springs and hacksaw blades. Embrittlement that cannot be prevented is overcome by boiling in water for a few minutes, or by baking at moderate temperature, after scale is removed. Operation may be full-automatic or semi-automatic. The process is inapplicable where this sheet strips or wire unable to carry the current required are involved, also for steel, iron or malleable castings which have a "skin" containing silica inclusions. Deep recesses necessitate inside anodes, at times, for best results. WHB(12k)

Preparation of Automobile Bodies for Lacquer Finishing. *Metal Cleaning & Finishing*, Vol. 2, Jan. 1930, pages 49–51.

Steel bodies in the plant of the Graham-Paige Motor Car Co., are given a preliminary wiping with oleum spirits. Rusted areas are rubbed with an abrasive and are spotted with a material similar to the spray material. The bodies are then sprayed with a patented composition containing H_3PO_4, colloidal clay fillers and solvents, having the consistency of paint. They are passed through an oven heated to 225° F., time taken being about 16 min. The dry coating is removed from the sides by metal bristle brushes. Steel shavings are used to remove the cleaner from the front end and back panels. MS(12k)

Polishing & Grinding (12l)

Polishing and Buffing of Stainless Steel. C. C. Snyder (Central Alloy Steel Co.). *Metal Cleaning & Finishing*, Vol. 2, April 1930, pages 313–316.

For most flat work, grinding should be started with No. 80 to 120 grit wheels, usually dry. Artificial abrasives are recommended up to No. 200 and black emery from No. 200 up. The No. 120 abrasive should be followed up by No. 150 and then by No. 180. For a mirror finish, it is necessary to continue with 200 abrasive and grease, then flour emery, followed by buffing. Drawn shapes are polished on a cushion type or soft wheel coated with No. 150 artificial abrasive using grease, at a speed of 6000 ft./min. This is followed by 180 abrasive with grease, No. 200 block emery with grease and finally 3 F flour sized emery. A stainless steel buffing compound on a cushion or soft type buffing wheel at a speed of 7200–8200 ft./min. is used for buffing. A color buff with Cr_2O_3 is then used. Bars and tubes, after having scale removed by pickling, are polished by means of a polishing belt. No. 60 or 80 dry artificial abrasive is used as a start. This is followed by 120, dry, and then 150, with grease. MS(12l)

Polishes Radiator Shells on Automatic Machine. *Steel*, Vol. 87, July 3, 1930, page 69.

Ford Motor Co. uses automatic machines to polish corrosion-resistant steel radiator shells. Machine consists of 2 principal units, the overhead mechanism for rotating and traversing the polishing wheels, and the conveyor on which are located fixtures of the indexing type for holding the work. Peripheral velocity is 9000 ft./min. For rough polishing, wheels set up with No. 120 manufactured Al_2O_3 are used, followed by No. 150 wheels, both being worked dry. Finishing is done with wheels set up with No. 120, 180 and 200 Turkish emery. The last 2 wheels are greased. Buffing is done on a machine similar to those used for polishing. MS(12l)

Polishing and Buffing of Automobile Hardware. *Metal Cleaning & Finishing*, Vol. 2, Jan. 1930, pages 21–22.

Describes practice of Oakland Motor Car Co. Radiator shells are rough polished on a No. 120 emery wheel at 2000 r.p.m. They are then polished with a 10 in. rag wheel coated with No. 150 abrasive, followed by using a 12 in. sheepskin wheel coated with No. 220 abrasive, with grease as lubricant. Ni plate is buffed with a 14 in. rag wheel, using a white lime buffing compound, at 2200–2400 r.p.m. Cr deposit is buffed with a special Cr_2O_3 grease compound, using a rag wheel at about 2500 r.p.m. Rustless Fe is buffed with a special 8 in. rag wheel at 3000 r.p.m. Abrasive is a Cr_2O_3 compound, lubricated with kerosene. MS(12l)

Coloring (12m)

Color Finishes of Aluminum. *American Metal Market*, Vol. 38, Jan. 21, 1931, page 10.

By treatment in a solution of certain chemical salts under carefully controlled conditions, aluminum shingles are given a durable shade of gray. Brown shades are also obtainable. Oxide coatings electrochemically deposited on the article acting as anode are becoming prominent. Anodic oxidation in chromic acid produces a coating of high corrosion-resistance and is widely used on aircraft parts of the duralumin type alloys. In a special solution an oxide film with strong affinity for certain types of organic dyes is produced. The coating may be dyed in an almost infinite variety of colors. An oxide film 0.0004 inch thick possesses an abrasive resistance 5–10 times as great as 5 coatings of baked enamel. A thickness of 0.0002 inch is sufficiently flexible not to crack with ordinary bending of the sheet. WHB(12m)

Filing (12o)

Burs and Files and Aluminum Castings. *American Machinist*, Vol. 73, Oct. 23, 1930, pages 669–671.

Describes filing machines and processes used in filing aluminum products in Fairfield, Conn. plant of Aluminum Company of America. RHP(12o)

Spinning (12p)

Spinning Gruss Air Spring Dome Heads on Steel Tubing. *Iron Age*, Vol. 126, Oct. 30, 1930, pages 1224–1225.

Dome head made on large sections of steel tubing by expanding and spinning the metal while hot. Tube is made into cylindrical sleeve which is a sliding inner member in the Gruss air spring used on motor buses and trucks. Method and equipment were developed by the Cleveland Pneumatic Tool Co. VSP(12p)

ECONOMIC (16)

Rare Metals. Cobalt, Molybdenum, Tantalum, Titanium, Tungsten, Radium, Uranium, and Vanadium in 1929. Paul M. Tyler & Alice V. Petar. *Mineral Resources of the United States*, 1929—Part I, pages 79–116, *United States Bureau of Mines*, December, 1930.

In 1929 the United States produced no Co. Patents and technical developments are covered in abstracts of 15 references. Mo ore and concentrates produced in 1929 contained about 4 million lbs. of metallic Mo, an increase of 17% over 1928. Patents and technical developments are indicated in abstracts of 24 references. Columbite production (Ta), all by one company, decreased from 34,899 lbs. in 1928 to 22,117 lbs. in 1929. Developments in technology are shown by abstracts of 12 articles and 7 patents. The production of Ti is not given. General conditions in the industry are discussed and abstracts of 31 articles are appended. Sales of W dropped in 1929 to 830 tons of concentrate carrying 60% WO_3. Details of domestic and foreign production are discussed. Articles (24) and patents (21) issued during 1929 are abstracted. Domestic and foreign developments in the production of Ra and U are described and supplemented by abstracts of 22 articles. The consumption of V in the United States in 1930 is estimated at 1,800,000 lbs. Over 90% of the world's supply is under American industrial control, but only about 16% of it occurs in deposits within the United States. 6 articles and 5 patents are abstracted. AHE(16)

Forging Costs Cut by Systemization. H. R. Simonds. *Iron Trade Review*, Vol. 86, Jan. 23, 1930, pages 27–30.

Account of the plant and forging practice of the Spicer Mfg. Co., South Plainfield, N. J. MS(16)

PLANTS & LABORATORIES (17)

Design and Construction of a 750/850 mm. 2-High Mill of the Dortmunder Union. (Entwurf und Bau einer 750/850er Duostrasse der Dortmunder Union.) J. MEISER. *Stahl und Eisen*, Vol. 50, Nov. 20, 1930, pages 1633–1638.

Report 79 of the Rolling Mill Committee of the Verein deutscher Eisenhüttenleute. Includes discussion. After discussing the reasons for the construction of the new mill a detailed description is given of the mill, including all supplementary machinery such as cranes, Siemens-regenerative pusher furnaces, saws, shears, cooling beds, etc. The rolling program of the mill consists of billets, slabs, beams, angles, rounds, squares, flats, light rails and special profiles such as sheet piles. The average tonnage/18 hrs. amounts to 750 tons. Under favorable conditions, a maximum tonnage of 1100 tons can be rolled for certain profiles. GN(17)

Develops Grain Flow Control. J. B. NEALEY. *Iron Trade Review*, Vol. 86, June 12, 1930, pages 57–60; *Heat Treating & Forging*, Vol. 16, July 1930, pages 905–907; *Fuels & Furnaces*, Vol. 8, June 1930, pages 773–778.

Champion Machine & Forging Co., Cleveland, Ohio, manufactures automotive and aircraft drop forgings. Billets are heated uniformly throughout the entire cross-sectional area to 2100°–2300° F., in a reducing atmosphere. The hot steel is placed skillfully in the various dies and the hammering is so regulated as to cause the grain to flow along the lines previously determined and blue printed by the forging engineers. The forgings are normalized at 1575°–1625° F., reheated to just above the critical temperature, cooled in the furnace or in the air, reheated to above the critical temperature again, quenched in oil or water, and drawn at 1000°–1200° F. MS(17)

Foundry Pours 4000 Tons Monthly. J. B. NEALEY. *Iron Trade Review*, Vol. 86, May 22, 1930, pages 51–54.

Describes the No. 1 foundry of the Allis-Chalmers Manufacturing Co., Milwaukee, which is used for heavy castings. Parts are molded continuously. All pouring is direct from cupola to flask. MS(17)

Apparatus Saves Foundry Labor. J. B. NEALEY. *Iron Age*, Vol. 126, Aug. 14, 1930, pages 418–421, 446.

Describes modernization of 2 foundries of Allis-Chalmers Mfg. Co., Milwaukee. Metal is produced in 6 cupolas. One of these is for chilled Fe. More than 4000 tons of metal is poured monthly in this foundry, while No. 2 foundry has a capacity of 2500 tons. For tractor parts a continuous molding unit is used. Insulated core ovens are employed. Firing is by means of two-pipe system. VSP(17)

Furnaces for the Carburizing Department. J. B. NEALEY. *Machinery*, Vol. 37, Sept. 1930, pages 25–26.

A carburizing compound has been developed by the Tool Steel Gear & Pinion Co. which is said to give uniform hardness throughout the depth of the case which ranges from $^3/_{16}$ to $^1/_4$ in. Most of the steel used is 0.15 to 0.20% C steel. After carburizing, the surface contains 0.90 to 1.20% C. Surface hardness 90–100 scleroscope. Furnaces used are of car-bottom type and can be used interchangeably for carburizing and other heat treatments. Gas is used for fuel. Describes the furnaces. One is a new type. It is brick steel encased, heated with 6 gas-blast burners, 3 on each side, car-bottom type, 9 ft. wide, 14 ft. deep, 10 ft. high. Top of car is of refractory, material, with piers, on the top a series of rails with notches at close intervals. Alloy steel tubes support the work and rest in these notches. Burners fire under the tubes. One large door in the front which is locked by a cam on each side. RHP(17)

Strip Steel Mill of the Acme Steel Co. J. B. NEALEY. *Blast Furnace & Steel Plant*, Vol. 18, Aug. 1930, pages 1277–1279.

Describes equipment in the strip mill at Riverdale, Ill., with special reference to the lead annealing pots, galvanizing and japanning installation, and slab furnaces. MS(17)

Strip Steel Annealed, Galvanized and Japanned Continuously. J. B. NEALEY (American Gas Association). *Iron Age*, Vol. 126, Oct. 2, 1930, pages 919–925.

Describes plant of Acme Steel Co., Chicago. Most interesting feature is an installation which takes a strip of steel and anneals, cools, pickles, washes and galvanizes it continuously, automatically and at high rate of speed. VSP(17)

Inland—A Midwestern Steel Company. CHARLES LONGENECKER. *Blast Furnace & Steel Plant*, Vol. 18, Jan. 1930, pages 153–164, 169–177.

Description of the blast-furnaces, coke-ovens, open-hearth furnaces, rolling-mills and other equipment of the Inland Steel Co., Indiana Harbor, Ind. MS(17)

Demonstration of Confidence in Research. R. S. MCBRIDE. *Chemical & Metallurgical Engineering*, Vol. 37, June 1930, pages 352–353.

Describes the research laboratory of the Aluminum Company of America, especially from the point of view of chemical engineering research. See article by Richard Rimbach, *Metals & Alloys*, Vol. 1, Sept. 1930, pages 717–720. MS(17)

Forge Shop Design Results in Efficient Operation. R. H. ALLEN. *Iron Trade Review*, Vol. 86, May 15, 1930, pages 47–50, 57.

Description of the lay-out and equipment of the Lefere Forge & Machine Co., Jackson, Mich. Has 12 oil-forging forging furnaces heating stock to 1600° F. MS(17)

The Basic-Bessemer Steelworks of the Mannesmann Tube Works. J. POSTINETT. *Iron & Coal Trades Review*, Vol. 121, Sept. 5, pages 326–327.

Taken from *Stahl und Eisen*. See *Metals & Alloys*, Vol. 1, Nov. 1930, page 854. RHP(17)

The Cardiff Blast Furnace Plant of the British Iron & Steel Company Limited. *Iron & Coal Trades Review*, Vol. 121, Aug. 1, 1930, pages 151–153.

Describes and illustrates the equipment of the plant. Discusses capacity, charging gear, hoists, gas-cleaning, stoves, casting equipment and blowing plant, boiler plant and raw materials used. RHP(17)

Electro-Galvanizing at Oakfield Steel-Wire Works. *Iron & Coal Trades Review*, Vol. 121, July 18, 1930, pages 77–79.

Describes the plant of the Whitehead, Hill & Company, Ltd. Deals with equipment and methods used in galvanizing steel wire. RHP(17)

Plant for Making Large Steel Castings. CHARLES LONGENECKER. *Blast Furnace & Steel Plant*, Vol. 18, April 1930, pages 622–623, 626; *Heat Treating & Forging*, Vol. 16, April 1930, pages 484–486.

Describes plant and equipment of the Ohio Steel Foundry Co. at Lima, Ohio. MS(17)

Tube Mill of the Laclede Tube Company. CHARLES LONGENECKER. *Blast Furnace & Steel Plant*, Vol. 18, May 1930, pages 781–783, 824.

Illustrated description of the equipment for and methods of manufacturing butt welded tubes of Bessemer and open-hearth steel. Annual capacity is 45,000 tons. Includes galvanizing and enameling facilities. MS(17)

Heat-Treating Furnaces Distributed in Line of Machine Shop Production. H. E. SCARBROUGH. *Iron Age*, Vol. 126, Aug. 7, 1930, pages 357–359.

Describes installation of General Electric furnaces of total connected load of 2745 kw. for Caterpillar Tractor Co. Furnaces are placed in line to facilitate the addition of other units in case of expansion. Leeds & Northrup temperature control instruments are used. Plant will average between 8 to 10 lbs. of heat treated parts/kwh. VSP(17)

Steel Foundry Specializes in Railroad Castings. NORMAN F. HINDLE. *Foundry*, Vol. 58, June 15, 1930, pages 42–47; July 1, 1930, pages 113–116.

Describes plant of Scullin Steel Co. specializing in production of side frames and bolsters. There specialties absorb 90% of foundry tonnage. Remainder of metal is used for car, locomotive and miscellaneous castings such as sugar mill machinery, rolls, gears, propellers, etc. VSP(17)

Ovens for Drying Crank Case Cores. *Heat Treating & Forging*, Vol. 16, April 1930, pages 512–513.

Studebaker Corporation, South Bend, Ind., has installed equipment which consists essentially of a monorail conveyor on which the cores are conveyed in racks through a 4-pass, 2-compartment continuous core-oven. The ovens are heated by one down-draft induced draft heater, each compartment being supplied by an independent fan operated from a common mixing chamber. Cores are dried by hot air at temperatures of 500°–700° F., depending upon the load. There are hot zones in each oven compartment. Each compartment handles 170 cores, each weighing 26 lbs., per hr. Drying time is 3 hrs. Cores after being black washed are dried in the black-wash oven, which is located directly under the core-oven, and is heated by air exhausted from the core-oven. Average gas consumption for 100 cores is 2200 cu. ft. of 530 B. t. u. gas. MS(17)

Welding Revolutionizes Manufacturing. *Iron Age*, Vol. 125, June 19, 1930, pages 1818–1820, 1868.

Describes how manufacturing methods at Bauer Brothers Co. have been revolutionized by the application of welding. Foundry and machine shop have been replaced by shear, punch and welding departments. Machining is reduced to a minimum. VSP(17)

Columbia Steel Corporation Operations. W. R. PHIBBS (Columbia Steel Corp.). *Mining & Metallurgy*, Vol. 11, April 1930, pages 205–206.

Read before Utah section of the American Institute of Mining Engineers, Jan. 9, 1930. Ore used is shipped from Desert Mount, Utah. It is a hematite disseminated with magnetite. Screening the ore and charging into furnace in layers of the sand size has resulted in decrease of coke consumption. Koppers Becker-type coke ovens are used. The by-products produced are ammonium sulphate, tar and motor fuel. The highest volatile coal is used and the coke is fast and free-burning. The company owns mills at Pittsburgh, Pa., and Torrance, Cal. VSP(17)

British and Continental Open-Hearth Furnace Steel Works. H. C. WOOD. *Engineering*, Vol. 130, Sept. 19, 1930, pages 373–377; Oct. 3, 1930, pages 447–448. Discussion, page 417.

Condensed from paper read before the Iron & Steel Institute, Prague, Czechoslovakia, Sept. 16, 1930. LFM(17)

A Modern Industrial Research Laboratory. *Machinery*, Vol. 36, Aug. 1930, pages 949–950.

Describes the new research laboratory of the Aluminum Company of America at New Kensington, Pennsylvania. RHP(17)

The Metallurgical Laboratories of the Ontario Research Foundation. R. RIMBACH. *Metals & Alloys*, Vol. 1, Nov. 1930, pages 816–818.

Ontario Research Foundation is endowed to the extent of $3,800,000 for pure and applied research. The work is now in progress in behalf of the textile industries, the packing industries and the metallurgical industries. The structure arrangement and facilities are described and photographs shown to clarify the description. ESC(17)

Machine Paced Founding. *American Machinist*, Vol. 73, Nov. 20, 1930, pages 811–814.

Description of the foundry of the Caterpillar Tractor Co., Peoria, Ill. RHP(17)

Research Building Designed for Broad Use of Steel and Aluminum. *Iron Age*, Vol. 126, Oct. 23, 1930, pages 1149–1150.

Describes new research and engineering building now being constructed for the A. O. Smith Corp., Milwaukee. VSP(17)

Interesting Oven Installation at Wright Aeroplane Plant. *Fuels & Furnaces*, Vol. 8, April 1930, pages 500–504, 512.

Description of installation in the foundry of the Wright Aeronautical Corp., Paterson, N. J., consists of oil-fired, continuous core baking oven; gas-fired closet model ovens for pasting and blacking cores; electric aging and drawing oven; oil-fired ovens for heating castings prior to welding; electric continuous type oven for shrinking heads on cylinders; 2 compartment electric japanning oven; and 3-compartment electric enameling oven. MS(17)

Extremely Large Furnaces Used in the Manufacture of Aluminum Structural Shapes. *Fuels & Furnaces*, Vol. 8, May 1930, pages 637–638, 646.

Installation at the Massena, N. Y. plant of the United States Aluminum Co., consists of 4 coke-fired open-hearth furnaces for melting pig Al; electrically heated furnace with 14 pits for preheating the ingots to 850°–950° F.; oil-fired, conveyor-type, billet heating furnace; electric heat-treating furnace, 90 ft. long, inside dimensions, with 26 zones; and a steam-heated aging oven, 90 ft. long, inside dimensions. MS(17)

Modern Equipment Saves Time and Labor in New Foundry. *Iron Age*, Vol. 126, Sept. 25, 1930, pages 836–839.

Describes new equipment in the Charles City, Iowa Foundry of the Hart Parr Division of the Oliver Farm Equipment Co. VSP(17)

Produces Bars or Bands at 2000 Ft. a Minute. *Iron Age*, Vol. 126, Aug. 28, 1930, pages 558–559, 598.

Describes the Inland Steel Company's new merchant bar mill at the Indiana Harbor Works. VSP(17)

Tractor Plant Foundry Built for Mass Production. *Iron Trade Review*, Vol. 86, May 22, 1930, pages 57–60.

Brief description and illustrations of the foundry of the Caterpillar Tractor Co., Peoria, Ill. MS(17)

A Cluster Mill for Brass Strip. The New Plant of Emery Brothers, Ltd. *Metal Industry*, London, Vol. 37, Aug. 8, 1930, pages 125–126.

Electric Welding Equipment. *Electrical Review*, Vol. 107, Oct. 17, 1930, pages 652–655; Oct. 24, 1930, pages 707–708.
Descriptions of various British manufacturers' products now available. MS(18)

Chipping Billets with a Novel Machine. A. K. West. *Blast Furnace & Steel Plant*, Vol. 18, Sept. 1930, pages 1461–1462.
Description of a machine developed by the Bonnot Company, Canton, Ohio. It can be used to chip billets of any cross-section and any length up to 30 ft., without the necessity for any adjustments. MS(18)

MISCELLANEOUS (20)

Heating Elements. *Electrician*, Vol. 105, Nov. 28, 1930, pages 677–679.
An abstract from a contribution by the Research Dept. of Steatit-Magnesia A. G., Berlin, Germany on the causes of destruction of Cr-Ni resistance wires. Results of a recent research are given. Deliberate overloading of the resistance wire until it burnt out was attempted to permit study of the results. Chromium trioxide was formed by purely thermal reactions and the oxide mist migrated. The phenomena encountered in practice was reproduced in the laboratory and studied. The well known burning out of heating elements is caused by the wire. The colored deposits occurring so extensively without the chemical or electrolytic coöperation of the ceramic material serve as a proof that overheating has taken place. Where radiating heat is involved a glowing temperature of 900° is sufficient and resistance wires and strips heated to much lower temperatures should be employed where only low-temperature heating is required. If an arc occurs on the burning out of the heating wire the ceramic element is also injured by the action of the oxides. The actual conductivity at high temperatures of the ceramic material is less important than generally believed. Resistance to temperature change is due to design and shape as well as material. WHB(20)

Change in Structure of Copper Due to Plastic Deformation. C. H. Mathewson & Kent R. Van Horn. *Metal Stampings*, Vol. 3, June 1930, pages 547–548, 556.
From paper read before American Institute of Mining & Metallurgical Engineers. See "Directed Stress in Copper Crystals," *Metals & Alloys*, Vol. 1, May 1930, p. 527. MS(20)

Simplified Shell Design Effects Economies in Wire Wheel Manufacture. *Metal Stampings*, Vol. 3, Feb. 1930, pages 167–169.
Comparison of former and present operations employed in the forming and machining of hubs for wire wheels, at the plant of the Wire Wheel Corporation of America. MS(20)

Modern Plant for the Utilization of Blast Furnace Slag for Road Construction. (Neuzeitliche Anlage zur Verarbeitung von Hochofenschlacke zu Teerstrassen-Baustoff.) *Stahl und Eisen*, Vol. 50, Dec. 11, 1930, pages 1752–1753.
The new plant built by the Vereinigte Stahlwerke, Division August Thyssen Works–Duisburg-Hamborn is described in detail. The plant is built for a production of 80 tons of tar-macadam/hr. GN(20)

Chrome-Nickel Steel Symbols Standardized. *American Machinist*, Vol. 73, Dec. 25, 1930, page 1028 b.
List of symbols agreed on by 51 companies producing chrome-nickel steels under license by the Krupp Nirosta Co., New York. RHP(20)

Chemical Removal of Incrustations. *Engineering & Mining Journal*, Vol. 131, Jan. 26, 1931, page 64.
The chemical process described has been in use in many European mining companies for some times. The equipment consists of a small centrifugal pump, a mixing tank, and pipe connections and fittings. A condenser with a capacity of 10 tons of cooling water requires a mixing tank of one ton capacity, to permit correct mixing and feeding of the compound which should contain 2400–3000 lbs. of HCl 24° Be. to each 10 tons of water. The mixture is circulated through the condenser. The mixing tank is filled 9 times with water which is discharged into the condenser and the mixing tank half filled with water. The bottled hydrochloric acid is added slowly to avoid a rapid rise in temperature and to prevent splashing. The compound is circulated till the incrustations have dissolved, which is easily determined. The muddy liquid is then drained through the nipple. Cleaning and repairing time has been reduced from 5 days to about 36 hours. WHB(20)

Tube Mill Equipment Automatically Lubricated. *Rolling Mill Journal*, Vol. 4, Aug. 1930, pages 411–414, 434.
Describes and illustrates applications of positive pressure lubricating units to the equipment in the seamless tube plant of Spang, Chalfant & Co., Inc., at Ambridge, Pa. Each unit consists of an air plunger directly connected to a grease plunger. Air pressure of 80–110 lbs./in.^{2} gives a grease pressure of 600–700 lbs./in.^{2} Changing length of stroke of piston changes amount of grease fed. Cycle of operations is automatically regulated by an electric time controller. MS(20)

Plastic Deformation. (Zur Frage der bildsamen Verformung.) R. Mitsche. *Stahl und Eisen*, Vol. 50, Nov. 20, 1930, pages 1645–1646.
In order to study the plastic deformation of metals, a simple device was developed which allows the visual observation of the process of deformation on materials like clay or wax or paraffin. With these materials, the cast structure of high speed steels was stimulated so that the deformation of the various structural elements of such type of steel could be studied. GN(20)

Destruction of Metals by Insects. (Metallzerstörung durch Insekten.) Bauer & Vollenbruch. *Elektrotechnische Zeitschrift*, Vol. 52, Jan. 8, 1931, page 46.
See *Metals & Alloys*, Vol. 2, Feb. 1931, page 46. Ha(20)

The Development of Electrical Gas Cleaning in Industry. (Le development industriel de l'epuration electrique des gaz.) M. Leveque. *Revue de Metallurgie*, Vol. 27, Oct. 1930, pages 513–521.
The first industrial application of electrostatic precipitation was made by A. O. Walker in coöperation with Sir Oliver Lodge in 1885. In France, it is used in the present modification of Cottrell method for cleaning of blast furnace gas, carbon black precipitation and tin oxide fume recovery. The installation at Homecourt is described, where blast furnace gas is cleaned in 2 stages. The first installation takes care of 120,000 m.^{3}/hr. reducing its dust content below 100 mgs./m.^{3}. In the actual practice an average of 46.74 mgs./m.^{3} is obtained with the outside limits of 28.2 and 68 mgs./m.^{3} The second unit is designed to handle 60,000 m.^{3}/hr. and to reduce the dust content to less than 20 mgs./m.^{3} The gas leaving it contains on an average 14.5 mgs./m.^{3} of dust with the outside variations of 12.5 and 19.2 mgs./m.^{3} Energy consumption is practically the same for both units, being equal to 1.53 KWH/1000 m^3. of dry gas and 1.39 KWH/1000 m.^{3} of wet gas. 9 photographs of the installation are given and the plant described. JDG(20)

Reduction of Sulphur Dioxide. George J. Young. *Engineering & Mining Journal*, Vol. 131, Jan. 12, 1931, page 7.
J. W. Beckman reduced SO_2 with CO in the presence of a simple catalyst. A cylindrical chamber is heated by electrical means to maintain the contact mass at 800–1200°F. SO_2 mixed with natural gas or CO and passed through a contact mass discharges a gas from which elemental S condenses. The reactions are exothermic. Experiments have been confined to a laboratory scale. WHB(20)

The Physical Characteristics of Industrial Powders. H. Marshall. *Canadian Chemistry & Metallurgy*, Vol. 14, Nov. 1930, pages 314–316.
According to their mode of preparation powders fall into the following classifications: (1) ground igneous rocks or glasses and stamped metallic powders, (2) ground earths and rocks of softer types, (3) precipitated powders, and (5) sublimed powders and "fume" pigments. Points discussed include: wetting, the settling of powders from liquids, the theory of liquid films, emulsification of powders, adsorption phenomena, and the manufacture and packing of powders. A bibliography is appended. WHB(20)

On the Dezincification of Brass. (Ueber die Entzinkung von Messing.) G. Masing. *Zeitschrift für Metallkunde*, Vol. 23, Jan. 1931, pages 23–25.
This paper was presented at the Annual Meeting of the Deutsche Gesellschaft für Metallkunde, Berlin 1930, and deals with the phenomenon of brass dezincification in service with emphasis on condenser tubes. After a scientific treatment of the nature of this process the author discusses the complete prevention by additions of arsenic. EF(20)

A New Arrangement for the Granulation of Blast Furnace Slag with Water and Air. (Eine neue Einrichtung zur Granulierung von Hochofenschlacke mit Wasser und Luft.) F. Spiess. *Stahl und Eisen*, Vol. 51, Jan. 1, 1931, pages 10–14.
Report 116 of the Blast Furnace Committee of the Verein deutscher Eisenhüttenleute. Includes discussion. The lack of sweet water at the blast furnace plant of the Koninklijke Nederlandsche Hoogovens en Staalfabrieken necessitated the development of a new method of granulating blast furnace slag. In a spout, the molten slag is mixed with small amounts of water. At the end of the spout cold air is blown through nozzles upon hot and voluminous slag, thus performing the final granulation. Data on the consumption of water and air are given as well as information on the properties of the sand which may be used for cement fabrication as well as bricks for construction. GN(20)

Dry Granulation of Molten Blast Furnace Slag. (Trockene Körnung von flüssiger Hochofenschlacke in Granuliermühlen.) P. Berger. *Stahl und Eisen*, Vol. 50, Dec. 18, 1930, pages 1775–1778.
Report 115 of the Blast Furnace Committee of the Verein deutscher Eisenhüttenleute. Includes discussion. The article describes the equipment for the dry granulation of blast furnace slag; considers the cost of dry granulation and the properties of the sand obtained by this method of granulation. It is shown that an essential saving of coal is accomplished in producing a sand with a humidity of about 7%. This saving amounts to about 3 tons coal/1000 tons of granulated slag. GN(20)

The Lead Deposit Mirror. E. H. Bostock. *Brass World*, Vol. 27, Jan. 1931, page 9.
The lead-coated mirror is produced from lead acetate or nitrate with thiourea. Lead sulphide is deposited and has a rather dull bluish cast which deadens light reflections producing little or no glare. WHB(20)

How Steel Bends. C. B. Dean. *American Machinist*, Vol. 73, Oct. 9, 1930, page 585.
Gives lettered diagrams, and formulas based on these to find what allowance is to be made in flat sheet steel for bends. RHP(20)

Saw Making Fundamentals. S. Horace Disston (Henry Disston & Sons). *American Machinist*, Vol. 73, Nov. 6, 1930, pages 730–732.
Article is from an interview with S. Horace Disston. Considerable historical matter is given and some general material concerning present saw making at the Disston plant. RHP(20)

The Different Magnetic States of an Ion. G. Foex. *Transactions American Electrochemical Society*, Vol. 55, 1929, pages 97–103.
The ferrous ion has been found to occur in 3 distinct magnetic states. Measurements made with different samples of nickel sulphate ($NiSO_4.H_2O$) have, however, always given the value of 16 magnetons. (20)

Design of Castings. (Die Konstruktion von Gussstücken.) W. Schreck. *Giesserei-Zeitung*, Vol. 27, Mar. 15, 1930, pages 163–166.
It is shown that a large proportion of waste in castings can be traced to faulty design. Suggestions for proper design and construction are given. (20)

Safety Device to Avoid the Turning Over of Converters. (Sicherheitsvorrichtung gegen das Umschlagen von Konvertern.) E. Schwenzner. *Stahl und Eisen*, Vol. 51, Jan. 1, 1931, pages 17–18.
A simple counter balance safety device has been installed by the Demag Corporation, Duisburg, on the converters of the August Thyssen Plant—Hamborn of the Vereinigte Stahlwerke. GN(20)

Recovery of Small Amounts of Precious Metals with Zinc Sheet. (Rückgewinnung geringer Edelmetallreste mittels Zinkschrott.) Edmund R. Thews. *Deutsche Goldschmiede-Zeitung*, Vol. 33, Dec. 13, 1930, pages 580–581.
Ag and Au can be economically recovered from solutions by precipitation with Zn. Ag can be removed from solution more rapidly if the solutions are made slightly acid with HCl or H_2SO_4. To precipitate Au from cyanide solutions, the solution should be made acid. This is dangerous due to the liberation of HCN, but can be safely done if the solutions are first diluted with a large quantity of water. After the first precipitate is collected by filtration the last traces should be extracted by allowing the Zn to remain in the filtered solution for 24 hours. JLG(20)

A Model to Explain the Mechanism of Electrolysis. M. DeKay Thompson. *Metal Industry*, N. Y., Vol. 28, Aug. 1930, pages 384–385.
Paper presented before Electrochemical Society at St. Louis, May 29–31, 1930. See *Metals & Alloys*, Vol. 1, Sept. 1930, page 741. VSP(20)

The Manufacture of Gold Leaf. George M. Whiley. *Brass World*, Vol. 26, Dec. 1930, pages 323–324.
A description of the age-old industry of Au beating, from the November 1930 Bulletin of the Birmingham (England) Jewelers' & Silversmiths' Association. To pure fine Au is added a certain proportion of alloy—usually Cu or Ag. The mixture is melted in a crucible and cast into an ingot or bar which is passed again and again between highly burnished steel rollers with ever increasing pressure and frequent annealing, until a "ribbon," 1¼ in. wide and 2 yds. to the ounce, is obtained. The ribbon is cut into square pieces, weighing 6 grains and placed between the leaves of a "crutch" (consisting of 200 sheets of fine vellum) measuring 4 in. square. WHB(20)

Application of Maintenance Inspection Schedules to Steel Plants. J. B. Whitlock (American Rolling Mill Co.). *Rolling Mill Journal*, Vol. 4, Apr. 1930, pages 173–174, 182.
Points out the value of regular inspection schedules for obtaining uninterrupted operation in all departments of steel plants, especially where straight line production methods are employed. These schedules are developed and applied by the maintenance department to every piece of equipment. MS(20)

FOUNDRY PRACTICE & APPLIANCES (22)

The Detroit Rocking Electric Furnace as Applied to the Production of High Test Gray Iron. CARL H. MORKEN. *Iron and Steel Industry & British Foundryman*, Vol. 4, Dec. 1930, pages 87–90.

Paper presented at meeting of the American Electrochemical Society, Sept. 25, 26, 27, 1930. See *Metals & Alloys*, Vol. 2, Jan. 1931, page 15. CHL(22)

Pearlitic Cast Iron. H. J. YOUNG. *Proceedings Staffordshire Iron & Steel Institute*, Vol. 45, 1929–30, pages 66–75.

Includes discussion. One can make an all-pearlitic iron with 3.2% total C, 0.25% P, 0.75% Mn by lowering Si, raising Si and increasing S, or adding Cr, or lowering Si and adding Ni. An iron may be on the cementite or the ferrite side of a true pearlitic structure without its being evident under the microscope. Analysis for combined C involves inaccuracies, so one never knows when he has a pure pearlitic iron. In the Lanz process, an iron of such composition is chosen that the center of the casting will just be all pearlitic when cast in a cold mold, the outer portion and the thinner sections would then be white or mottled. But the dry sand mold is heated to such a temperature that all parts of the casting cool at a rate slow enough to give the pearlitic structure. Young says the idea that there are peculiar properties in a given brand of pig iron, not shown by its complete analysis, is false, and that given any brand of pig or hematite iron, he can, by addition of steel scrap, ferro silicon or ferro manganese, produce straight cast iron of any known quality. In discussion, Hoskison, a pig iron producer, took issue with this statement. To reduce wear of a cast iron engine cylinder, the piston rings should not be softer than the cylinder wall. Debris from the wearing of soft rings causes more wear on the cylinder than a hard ring. HWG(22)

Report of American Society for Testing Materials Committee A-3 on Cast Iron, with Appendix. Report of Sub-Committee XIII on High Test Cast Iron. *Proceedings American Society for Testing Materials*, Vol. 30, Part 1, 1930, pages 187–198.

See *Metals & Alloys*, Vol. 1, Nov. 1930, page 855. (22)

Melting Equipment for Aluminum. *American Metal Market*, Vol. 37, Dec. 16, 1930, pages 3, 12.

A bulletin by the National Smelting Co. discusses the type of melting equipment for foundries of small capacity and of large. Distinction is made between foundries with few alloy mixtures and those requiring a continuous supply of molten metal, and frequently having large runs of a single uniform alloy. WHB(22)

Standards for Copper Alloy Ingots. *Metal Industry*, N. Y., Vol. 28, Oct. 1930, page 479.

Revised tentative specifications for Cu base alloys in ingot form for sand castings, approved as tentative by the American Society for Testing Materials on Aug. 12, 1930, and by Non-Ferrous Ingot Metal Institute on Sept. 5, 1930. VSP(22)

Does Humidity Affect the Density of Red Brass Castings? N. G. NEAR. *Metal Industry*, N. Y., Vol. 28, Sept. 1930, page 416.

Observations show that during winter more difficulty is encountered in producing castings with less sponge than in other seasons. Factors responsible for spongy castings were eliminated. During winter, the moisture in atmosphere varied from 0.2 to 3 gr./ft.^{3}; during summer, from 3 to 16 gr./ft.^{3}. Metal melted during winter when steam is added to the air lines to supply the deficiency of moisture was found to be more dense and free from sponginess so prevalent otherwise. VSP(22)

The Founding of Bronze Gear Blanks. FRANCIS W. ROWE. *Metal Industry*, London, Vol. 36, June 27, 1930, pages 669–672; Vol. 37, July 4, 1930, pages 11–13.

See *Metals & Alloys*, Vol. 2, Feb. 1931, page 28. VSP(22)

A Riser. JOSEPH P. MCGINNIS. *Metal Industry*, N. Y., Vol. 28, Sept. 1930, page 423.

Describes a pattern for a bronze casting that is finished all over, with exception of bracket part. VSP(22)

Complexities in the Steel Foundry. FREDERICK A. MELMOTH (Detroit Steel Casting Co.). *Heat Treating & Forging*, Vol. 16, Aug. 1930, pages 1006–1008, 1014.

Address before the Steel Founders' Society of America. See *Metals & Alloys*, Vol. 2, Jan. 1931, page 15. MS(22)

Getting the Most Out of Steel Castings. H. A. MITCHELL (Bonney Floyd Co.). *Iron Age*, Vol. 126, Oct. 2, 1930, pages 914–917.

Heat treated plain C steel has properties equal or superior to many types of annealed alloy steel castings. By heat treatment is meant quenching and tempering as distinguished from annealing. Best properties of steel castings can be brought out only by quenching and tempering. Effect of various heat treatments. Dangers of quench cracks can be eliminated as follows: (1) Metal must be thoroughly refined before casting; (2) Charge to be quenched must be at uniform temperature; (3) Temperature to which castings are quenched is important. Any type of steel casting in annealed state shows practically the same properties regardless of method of manufacture. Includes graphs and tables. VSP(22)

Alloy Cast Iron and High Strength Cast Iron in the United States of America. F. B. COYLE (International Nickel Company). *First Communications of the New International Association for the Testing of Materials.* Group A. Zurich, 1930, pages 35–48.

Methods for production of high strength iron are, superheating in the electric furnace or the hot blast cupola, partial malleabilization of white iron, use of all steel scrap charge, graphitization of a white iron composition by addition of ferrosilicon and nickel in the ladle. The effects of addition of Ni and Cr are shown in modified Maurer diagrams which are given also in Coyle's article in Transactions American Society for Steel Treating, September 1927. HWG(22)

Improvement of Cast Iron by Alloying and Superheating. (Verbesserung von Gusseisen durch Legierung und Ueberheitzung.) E. SCHÜZ. *Mitteilungen aus den Forschungsanstalten des G.-H.-H.-Konzerns*, Vol. 1, Nov. 1930, pages 34–40.

Schüz claims that neither superheating nor alloying with Ni and Cr bring advantages to true cast iron corresponding to the cost. For true resistance to high temperatures (ability to stand 3 heatings to 1000°–1050° C. in gases of combustion of coal without losing over ½% by scaling) high Cr iron is useful. The dividing line between Fe-Cr alloys passing this test and those that do not, runs from 22½% Cr at 1% C to 19% Cr at 4½% C. However, in order to avoid proeutectic carbide these irons should not contain over 3% C. With carbon constant at 2½%, the line runs from 22% Cr at zero silicon to 14% Cr at 11% Si. A proper Si content tends to prevent cracking. Dilatometer curves are given to show the superiority of an iron with 2% Si over one of ½% Si, both with 25% Cr and 2% C. HWG(22)

High-Strength Cast Iron-Eutectic Cast Iron. E. OSANN. *Foundry Trade Journal*, Vol. 43, July 31, 1930, page 75.

Abstract translation of paper read before the German Foundry Technical Association. Discusses the advantages of eutectic alloys. VSP(22)

Malleable Iron Castings. (Temperguss.) B. OSANN. *Maschinenbau*, Vol. 8, Dec. 5, 1929, pages 785–789; Dec. 19, 1929, pages 832–834.

A discussion of melting, casting and annealing in pots and furnaces, cleaning and processing. Metallurgical processes, such as admixture of Mn, Si and S are considered, together with the causes of failures in annealing, strength qualities and the strength of malleable cast iron. (22)

Ratio of Metal Charged to Cupola Melting Speed is Important. W. N. TRUXELL (Potter Coal & Coke Co.). *Iron Age*, Vol. 126, Aug. 28, 1930, pages 544–555.

From an address before the Pittsburgh Foundrymen's Association, May 19, 1930. Weight of the metal charged in proportion to melting speed is the established variable. Cupola will not operate on a higher efficiency on steel than on Fe. Increasing metal charge decreased loss from spongy sections, and does not injure smaller castings. Melting point of steel scrap decreases as C content increases. Steel is used to make gray Fe stronger and tougher. VSP(22)

Melts Gray Iron for Stove Plate in the Electric Furnace. N. L. TURNER. *Foundry*, Vol. 58, Aug. 1, 1930, pages 88–89.

Advantages of continuous operation of electric furnace for this class of castings are as follows: (1) production of castings increased 25 to 30%; (2) cost of Fe at spout is less than previously obtained; (3) flexibility of the method. Ideal stove plate gray Fe analysis is within following ranges: C 3.25–3.35%, Si 2.75–2.85%, P 0.60–0.70%, Mn 0.45–0.60%, S less than 0.09%. Gives electric furnace cost for one month. Data procured from Black Foundry, Ltd., Ottawa, Canada. VSP(22)

Briquetting Borings Reduce Gray Iron Melting Costs. FRED J. WALLS (Wilson Foundry & Machine Co.). *Foundry*, Vol. 58, July 15, 1930, pages 68–70; *Foundry Trade Journal*, Vol. 43, July 24, 1930, pages 59–62; *American Machinist*, Vol. 73, Aug. 7, 1930, pages 245–249.

Abstracted from paper presented in behalf of the American Foundrymen's Association before the Institute of British Foundrymen, June 17–20, 1930. Of the various methods used for binding together cast Fe borings, the best results are obtained by compacting the borings under pressures into briquets which withstand rough usage without disintegrating. Gives cost figures and results obtained in melting varying amounts of briquets in the cupola. VSP+RHP(22)

Accurate Finish for Match Plate Patterns. PAUL H. WHITE. *Iron Age*, Vol. 126, Oct. 30, 1930, pages 1214–1215, 1277.

Describes method employed in making a match plate for an irregular shaped part. VSP(22)

Low Carbon Cupola Cast Iron. (Niedriggekohltes, schmiedbares Gusseisen aus dem Kupolofen.) W. VALENTIN. *Giesserei-Zeitung*, Vol. 27, Nov. 15, 1930, pages 617–621.

The article gives results of tests on cast Fe produced according to the Corsalli method. The C content could be essentially decreased, so that contents between 0.99 and 1.26 C were found. The structure of these cast irons does not show any free graphite. The tensile strength of sand cast Fe of this composition increases up to 50 kg./mm.^{2} In chilled and annealed castings of this composition, a tensile strength up to 97 kg./mm.^{2} was observed. GN(22)

The Economic Utilisation of Compressed Air in Steel Foundry Practice. T. W. BARLEY. *Foundry Trade Journal*, Vol. 43, July 17, 1930, pages 39–40; *Edgar Allen News*, Vol. 9, Dec. 1930, papes 765–768.

From a paper read before the Institute of British Foundrymen. The outstanding points to be considered to ensure economy in compression and use of air in foundries are: (1) Where possibly a central station should be installed and compressors of guaranteed output used; (2) Volume and pressure recorders for the air, and power recorders for prime movers; daily readings to be taken; (3) Test for leaks periodically; (4) High-grade oil to be used; (5) Valves and moving parts of air tools should have close attention. VSP(22)

FURNACES & FUELS (23)

A New Method for Regulating Electric Furnaces. (Un nouveau mode de règlage des fours électriques à électrodes.) PAUL BERGEON. *Journal du Four Electrique*, Vol. 39, June 1930, pages 209–211.

Instead of regulating the furnace by moving the electrodes, the voltage can be varied thus having the electrodes fixed all the time. The voltage is varied by the use of multiple taps in 56 different positions on the primary, giving a variation of from 24.18 to 56 volts for the secondary. Miguet and Perron furnaces are operated by varying voltage. GTM(23)

Electric Black Annealing Furnaces. (Elektrische Schwarzglühöfen.) H. LANGENBACH. *Elektrizitätswirtschaft*, Vol. 29, Jan. 1, 1930, pages 12–13.

Favorable results obtained with furnaces for annealing of polished stock have led to the electrification of coal-fired furnaces. Performance characteristics and economies in operation of this furnace are explained on the basis of production. (23)

Bright-Annealing by the Grünewald Process. R. W. MÜLLER. *Metallurgia*, Vol. 3, Dec. 1930, pages 69–70.

Translated from *Metallwirtschaft*, Vol. 9, June 20, 1930, pages 525–527. See *Metals & Alloys*, Vol. 2, Feb. 1931, page 49. JLG(23)

Conveyor Furnaces Heat Treat Small Parts. *Iron Trade Review*, Vol. 86, March 27, 1930, page 61.

Hevi Duty Electric Co., Milwaukee, has developed a furnace for quantity heat treatment of small automotive or machinery parts. Conveyor consists of a 3/16 in. woven-mesh belt of the floating reinforcement type, composed of heat-resisting Ni-Cr alloy wire. Belt is supported on driven rollers through the furnace chamber which imparts the driving impulse uniformly at closely adjacent points. No hearth plate is used. Furnace with a hearth 1½ by 12 ft. heats 1000 lbs. of parts an hour to 1550° F. MS(23)

Properties and Use of Zirconium Products. (Ueber die Eigenschaften und Verwendung von Zirkonerzeugnissen.) *Zeitschrift für die gesamte Giessereipraxis*, Vol. 50, Sept. 8, 1929, pages 143–144.

The excellent refractory properties of Zr make it of special value for use in industrial furnaces. The compositions of a few Zr products are listed. (23)

Low-Pressure Steam Improves Drill Furnace Operation. *Engineering & Mining Journal*, Vol. 131, Jan. 26, 1931, page 54.

At the central drill-sharpening shop of the Copper Queen branch of the Phelps Dodge Corp. at Bisbee, Arizona, new oil-fired rock-drill furnaces feature the use of steam in place of air for combustion. Introduction of steam at 12 lbs. pressure results in a moist flame which effects a slightly reducing atmosphere within the combustion chamber of the furnace, preventing decarbonizing and scaling of the steel during the heating process. Air is used to start the furnace and to generate the necessary amount of steam. The method of using steam in the rock-drill furnace is shown by a chart. WHB(23)

Special Furnaces to Heat Treat Axles and Gears. *Iron Age*, Vol. 126, Oct. 16, 1930, pages 1061–1065.

Describes new heat treating equipment installed at the plant of the Eaton Axle & Spring Co., Cleveland. Axle shafts and gears and pinions for automobiles are heat treated in new continuous automatic gas-fired furnaces. Carburizing furnace is of the counter flow recuperative type. Gears and small pinions are made of 3.5 and 5% Ni steel. The 5% Ni steel is used mostly for drive and differential pinions. They are carburized at 1650° F. for 10 hrs. and remain in furnace about 24 hours. Suction system is used for cleaning carburized parts. Furnace for hardening gears is an electric double-deck continuous roller hearth furnace of 120-KW capacity. Gears and pinions made of 3.5 Ni steel are hardened at 1480° F. and those made of 5% Ni steel are hardened at 1460° F. Cleaning unit for removing scale and oil is feature of plant's equipment. VSP(23)

Electric Ovens for Aircraft Engine Parts. PHILIP KRIEGEL. *American Machinist*, Vol. 73, Dec. 25, 1930, pages 1007–1009.

Discusses types of electric ovens used by several aeroplane companies in the heat treatment of parts. Gives temperatures at which various parts are treated. RHP(23)

Source of Heat for Heat Treatment. ROBERT M. KEENEY. *Metals & Alloys*, Vol. 1, Oct. 1930, pages 755–759.

A general discussion is offered concerning the merits of bituminous coal, anthracite coal, powdered coal, fuel oil, butane, natural gas, city gas and electricity for heat treating. The latter 5 prove satisfactory for this purpose. An itemized analysis of the various units of auxiliary equipment is offered together with comment on the hazards. An oil fired furnace operates with a net efficiency of 7.1 to 17.0%; a gas fired furnace operates with an efficiency of 35%; and an electric furnace, with an efficiency of 72%. Considerable attention is devoted to furnace atmosphere such as CO_2, H_2, H_2O vapor, air, CO, CH_4, illuminants for hardening and drawing. In the matter of bright annealing, atmospheres of H_2O vapor, CO, H_2, N_2, and Electrolene are useful. ESC(23)

Design and Heat Utilization, Open-Hearth. *Blast Furnace & Steel Plant*, Vol. 18, Feb. 1930, pages 299–301.

From *Demag News*. Describes recent improvements in the Moll-Demag open-hearth furnace. Air and gas are mixed in a mixing chamber in much the same way as in a Bunsen burner. In the latest designs the air chambers are carried over the furnace platform on the outside ends of the furnace, resulting in a preheating of the air to 2550° F. The bulky, heavy port heads of the normal open-hearth furnace have been eliminated. Removal of slag from the regenerator chambers is facilitated by the substitution of removable slag boxes for the usual slag chambers. Gives results obtained with a Thyssen-type waste-heat boiler with smoke-tubes and superheaters. MS(23)

High and Low Pressure Air for Furnaces. C. F. OLMSTEAD (Mahr Manufacturing Co.). *Heat Treating & Forging*, Vol. 16, June 1930, pages 778–780, 785.

Shows that air from a fan or blower is more economical than that from a compressor, when used in oil burners and as a protecting curtain. Not only is there a saving in power costs, but the linings last 50% or more longer. Better heating of the steel is obtained with low pressure air. MS(23)

Blast Furnace Gas as a Metallurgical Fuel. JOSEPH F. SHADGEN (Smoot Engineering Co.). *Iron Age*, Vol. 126, Nov. 6, 1930, pages 1287–1789.

Blast furnace gas is the 3rd product of the process of reducing ore into pig Fe. Approximately 50 to 55% of heat content of coke charged with ore leaves furnaces in form of gas. Major uses of blast furnace gas are for: (1) stoves; (2) boilers; (3) metallurgical furnaces. Surplus gas available per ton of pig Fe is about 95,000 to 100,000 cu. ft. S is the most objectionable impurity in fuel. Producer gas is the standard fuel used in coke ovens, open-hearth furnaces, soaking pits, heating furnaces, etc. VSP(23)

Gas Mixtures for Multi-Fuel-Fired Furnaces. JOSEPH F. SHADGEN (Smoot Engineering Co.). *Iron Age*, Vol. 126, Nov. 13, 1930, pages 1374–1375, 1436.

Surveys the field with regard to the principal available fuels and shows how a gas mixture of any desired heating value may be obtained by blending 2 or more common gases. Blast furnace and coke oven gases are used for all operations that have baseload characteristics. Producer gas and oil are best suited for peak load demand. Multi-fuel-fired furnaces should be equipped with apparatus to regulate air for fuels in addition to proper draft control for removal of waste gases. VSP(23)

Modern Methods of Testing Coke. (Neuzeitliche Verfahren der Stückkoks-Prüfung.) WOLFGANG MELZER. *Archiv für Eisenhüttenwesen*, Vol. 4, Nov. 1930, pages 225–238; *Stahl und Eisen*, Vol. 50, Nov. 27, 1930, pages 1675–1676.

Report 36 of the Coke-Plant Committee of the Verein deutscher Eisenhüttenleute. Next to the determination of the chemical composition of a coking coal, the determination of some physical properties are of importance in order to find a suitable application for any type of coke. This testing should include the determination of the reactivity, the porosity, the strength and the friability. For testing the reactivity, the inflammability was determined by means of the Bunte method which was improved for this investigation. Not only does the reactivity of individual coke particles vary, but also the reactivity of coke particles taken from various parts of a coke oven. It was found that the ignition point is dependent on the type in which the C of the coke is present. The porosity of the coke also changes within an individual piece as well as within an oven charge. The strength and friability were determined by the Simmersbach-drum method. The above 4 test methods permit the judging in any case of the suitability of various types of coke for different purposes. The blast furnace is the best practical indicator of the quality of a coke. GN(23)

The Testing of Coke Coals. (Die Prüfung der Kokskohlen.) WOLFGANG MELZER. *Archiv für Eisenhüttenwesen*, Vol. 4, Oct. 1930, pages 169–175; *Stahl und Eisen*, Vol. 50, Nov. 20, 1930, pages 1643–1644.

In order to qualify the coking qualities of coke coals, 3 different tests are applied in particular: the determination of the chemical structure of the coal; the determination of the chemical changes during the coking process; and the determination of the mineralogical structure. 20 different German coking coals were tested by these methods. GN(23)

High-Frequency Steel Furnaces. D. F. CAMPBELL. *Blast Furnace & Steel Plant*, Vol. 18, Oct. 1930, pages 1625–1628; condensed in *Electrical Review*, Vol. 107, Oct. 3, 1930, pages 554–555; *Fuels & Furnaces*, Vol. 8, Dec. 1930, pages 1639–1641.

Paper read before the Iron & Steel Institute. See *Metals & Alloys*, Vol. 2, Jan. 1931, page 16. MS(23)

Metal Melting by Oil Fuel. W. C. CATHCART. *Foundry Trade Journal*, Vol. 43, July 31, 1930, pages 77, 80.

Crucible coke-pit fires have advantages of low first cost, and are suitable for producing varied range of alloys. The metal output for given floor space is low. Coke-fired tilting crucible furnaces permit the melting up to 1/2 ton with a saving in fuel and floor space. Producer gas is cheap on a cost per thermal unit basis, but gas making plant uses too much space and expert supervision is required. Electricity is too costly. Liquid fuel on the other hand was a high calorific value and it can be burnt in pit or tilting furnace. More metal can be melted in oil fired furnace. Oil firing is suitable for melting pure Ni, Ni alloys and Al, etc. Oil is fed to burners by gravity. Compares results of melting 70–30 brass in 1/2-ton crucible furnaces using coke and oil as fuel. VSP(23)

Open-Hearth Combustion. W. P. CHANDLER, JR. *Proceedings Engineers' Society Western Pennsylvania*, Vol. 46, Oct. 1930, pages 241–263; *Fuels & Furnaces*, Vol. 8, Aug. 1930, pages 1069–1072, 1105.

The author discusses a number of factors to be considered in the economical operation of an open-hearth furnace. The heat requirements of the open-hearth process, the types of fuels available, methods of increasing the flame temperature, the value of preheating the air and gas, furnace regulation and the design of ports are discussed. MS(23)

Insulation Improves Operation of Malleable Iron Annealing Furnaces. *Fuels & Furnaces*, Vol. 8, May 1930, page 716.

Arches of 3 pulverized-coal-fired furnaces at the Sacks-Barlow Foundries, Newark, N. J. were insulated, resulting in more uniform temperatures throughout the furnaces, and a saving in fuel of almost 20%. MS(23)

Electric Furnaces for Steel Metallurgical Works. (Fours électriques pour la métallurgie de l'acier.) *Genie Civil*, Vol. 96, Apr. 12, 1930, pages 349–352.

A description of several modern types of reverberatory arc furnaces, high-resistance furnaces. (23)

Some Points Pertaining to Heating. *Heat Treating & Forging*, Vol. 16, July 1930, pages 911–912.

From *World Power*. General discussion of the advantages of industrial electric furnaces from the points of view of both the consumer and the supplier of electrical energy. MS(23)

Heat-Treating Practice in Making Tractor Parts. *Iron Age*, Vol. 126, Sept. 4, 1930, pages 615–617.

Increased production, close temperature control and high quality of work have been effected at the plant of the Cleveland Tractor Co. by the use of a continuous electric furnace for heat treating. It is a chain belt conveyor type, built by the Electric Furnace Co. Furnace is used for hardening transmission gears, rollers, bushings and pins. The steels used are SAE 1020, a plain-C steel and SAE 3145, a Cr-Ni-Mo steel. Gives a description of the furnace. VSP(23)

Applications of Electric Furnaces. *Electrical Times*, London, Vol. 76, Dec. 12, 1929, pages 1035–1037.

Considers electric furnaces for the ferrous industry, reheating, sheet annealing, wire annealing, annealing of steel castings, malleabilizing of Fe, tempering, carburizing, tool steel hardening and for the non-ferrous industry including heat treatment of brass, Cu, German silver, etc., and the manufacture of Al. The growth of demand for electric heat-treatment furnaces from 1926 to 1929 is shown in graphs. (23)

Industrial Electric Furnaces. *Electrical Review*, Vol. 107, Oct. 17, 1930, pages 649–651; Oct. 24, 1930, pages 705–707.

Descriptions of various British manufacturers' products now available. MS(23)

Ford Forges with Electric Heat. *Electrical World*, Vol. 96, Nov. 15, 1930, pages 902–905.

At present the electric furnaces are used for heating only comparatively small forgings, universal joint housings, front wheel spindles, steering gear spiders, ring gears on their ends and the like. The silicon-carbide rods have superseded the carbon-trough type for ordinary forging operations. The simplest type is merely a sheet-steel or cast-iron shell with insulation and firebrick lining. The resistor bars are spaced across the top of the interior and their terminals brought out through ports in the sides. A slot 2–4 in. in height, running lengthwise on one side, allows the work to be placed in the furnace. Features are illustrated. WHB(23)

Fuel Economy at Skinningrove. FRANK BAINBRIDGE. *Blast Furnace & Steel Plant*, Vol. 18, July 1930, pages 1130–1134; Aug. 1930, pages 1293–1296.

Paper read before the Iron & Steel Institute. See *Metals & Alloys*, Vol. 1, Sept. 1930, page 744. MS(23)

Heat Treating Furnaces Become Production Machines. ROBERT M. COMSTOCK. *Iron Age*, Vol. 126, Sept. 11, 1930, pages 683–685, 722.

Continuous furnace is being applied to a wide variety of operations in production heat treating. Improved heat-resisting alloys have accelerated its development. Continuous annealing of metal strips is commanding widespread interest. Importance of atmospheric control in heating for heat treating in oil, gas and electric furnaces. Problem in heat treatment is quality production at low over-all cost of finished product. VSP(23)

Electric Furnaces. VERDON O. CUTTS (General Electric Co., Ltd., London). *Electrical Review*, Vol. 107, Oct. 17, 1930, pages 617–619.

Considers resistance-type furnaces and their various industrial applications. Most important advantage is the ease with which temperatures can be controlled. The present tendency is toward continuous-type furnaces. Among recent developments are the adoption of electric furnaces for bright annealing, vitreous enameling, hardening of high-speed steel, treatment of austenitic steels and melting of refractory metals. Such progress has been made possible by appreciation of the fact that, for many purposes, the electric furnace can compete with fuel-fired furnaces on a straight cost basis. Electric heating is an important factor in smoke abatement. MS(23)

Combustion of Blast Furnace Gas. T. J. ESS (Republic Steel Corp.). *Blast Furnace & Steel Plant*, Vol. 18, Oct. 1930, pages 1613–1618.

Deals with formation of gas in the blast furnace, its characteristics, quantity produced under different furnace conditions, uses, cleaning, use of heat interchanges and combustion. Includes charts. MS(23)

The Homo Furnace for Nitriding Steel. (Nitrierhärtung von Sonderstahl mittels des Homo-Ofens.) A. FRY. *Stahl und Eisen*, Vol. 51, Jan. 1, 1931, page 19.

The Homo nitriding furnace is briefly described and the uniformity of parts nitrided in this furnace is pointed out. The furnace is most desirable for nitriding fine mechanical parts such as gages, calipers, etc. GN(23)

Investigations and Proposals on the Regulation of Rolling Mill Furnaces. (Untersuchungen und Vorschläge zur Einregelung von Walzwerksöfen.) F. WESEMANN. *Stahl und Eisen*, Vol. 50, Nov. 13, 1930, pages 1601–1610.

Report No. 144 of the Heat Committee of the Verein deutscher Eisenhüttenleute. The article summarizes the results of an investigation of a rolling mill furnace heated with semi-gas. Proposals are made to improve the heat efficiency of the furnace. GN(23)

Bringing the Furnace to the Work. J. C. WOODSON (Westinghouse Electric & Mfg. Co.). *Electric Light & Power*, Sept. 1930, Sec. 2, pages 140, 145–146, 148.

Outline of the development of electric heat-treating furnaces and description of several types. MS(23)

Open Hearth Furnace, System Terni. (Siemens-Martin-Ofen, Bauart Terni.) F. H. SCHÖNWÄLDER. *Stahl und Eisen*, Vol. 50, Dec. 11, 1930, pages 1749–1750.

The new furnace type is claimed to have a higher ton/hr. output due to the construction of the ports which permit working with a short and hot flame during the melting down period of the charge, but with a long flame during the working period and the boil. Since the air is furnished by a fan, the velocity of the flames and the conditions of combustion can be regulated. The Terni Steel Works, Italy, reported the following results:

	Total production/campaign in tons	No. of heats
20 ton furnace, old type	8,500	450
20 ton furnace, new type	24,000	1000
40 ton furnace, old type	16,000	450
40 ton furnace, new type	45,000	1000

The fuel consumption amounts to 20%, and under, of the weight of the cold charge. The time on a heat varies between 4 and 5 hrs. on a 35 ton heat. Data are given on the consumption of refractories. GN(23)

REFRACTORIES & FURNACE MATERIALS (24)

Cold Crushing Strength of Fire Brick. H. K. MITRA. *American Ceramic Society Journal*, Vol. 13, Feb. 1930, pages 85–87.

The purpose of this investigation was to determine the cold crushing strength of fire brick in 3 directions: flat, edge and endwise. The possible mathematical relationship between the values of these crushing strengths and the best procedure for testing fire brick are considered. (24)

Lining and Relining Furnaces. JOSEPH P. MCGINNISS. *Metal Industry*, N. Y., Vol. 28, Aug. 1930, pages 372–373.

Includes comments by H. E. White Vice-Pres., Lava Crucible Co. of Pittsburgh. Gives practical methods to save time and expense. VSP(24)

Sillimanite Bricks for Construction Material of the Roofs of Electric Furnaces. (Sillimanitsteine als Gewölbebaustoff für Elektrostahlöfen.) F. SOMMER. *Stahl und Eisen*, Vol. 50, Nov. 27, 1930, pages 1676–1677.

Whereas previous investigations on the application of sillimanite bricks for electric furnaces showed failures due to the cracking of the bricks, the use seems to be more promising now since burned sillimanite bricks are manufactured. Practical results with burned sillimanite bricks are given which show that the bricks have about 2.3 times longer life than silica bricks. GN(24)

Investigation of the Slagging of Refractory Materials. Part III. The Slagging of Magnesite. (Untersuchungen über die Verschlackung feuerfester Stoffe. Teil III. Die Verschlackung von Magnesit.) R. MICKSCH & H. SALMANG. *Archiv für Eisenhüttenwesen*, Vol. 3, Oct. 1929, pages 313–318; *Stahl und Eisen*, Vol. 49, Nov. 28, 1929, pages 1724–1725.

In order to test the slagging properties of magnesite, slags of various composition were melted in crucibles of magnesite. 2 kinds of magnesite were used; the one containing 85.46% MgO and 8.36% Fe_2O_3, the other containing 88.61% MgO and 4.48% Fe_2O_3. Temperatures of 1550° and 1650° C. were used in the tests. In general, free basic oxides do not attack magnesite but phosphoric acid and boric acid do attack it. Lime has a more destructive effect than iron oxide, MgO and alkalies. Magnesite containing a larger amount of fluxing agents is more readily attacked than that with a lower amount. GN(24)

Progress in the Field of Refractory Materials. (Fortschritte auf dem Gebiete der feuerfesten Baustoffe Halbjahrsübersicht, Apr.-Sept. 1929.) E. H. SCHULZ, F. HARTMANN & A. KANZ. *Stahl und Eisen*, Vol. 50, Nov. 27, 1930, pages 1677–1681.

80 references are reviewed, covering (1) raw materials, properties, preparation and production methods, (2) furnace construction and operation, (3) testing methods and equipment, (4) properties, (5) quality specifications, (6) special bricks and new refractories, (7) cements and molding sands, (8) survey of literature. GN(24)

Refractory Brick and Its Manufacture. H. E. TOWNSEND (Hiram Swank's Sons, Inc.). *Blast Furnace & Steel Plant*, Vol. 18, Jan. 1930, pages 105, 195–196.

Elementary account. MS(24)

Use of Refractory-Maintenance Cements in the Non-ferrous Foundry. H. E. WHITE. *Fuels & Furnaces*, Vol. 8, June 1930, pages 851–852.

From paper read before American Foundrymen's Association, Mar 12–16, 1930. MS(24)

Higher Temperatures Create Need for Superior Refractories. *Iron Trade Review*, Vol. 86, Jan. 2, 1930, pages 31, 121.

Developments during 1929 as seen by several authorities. MS(24)

Investigations on the Slagging of Refractory Materials. Part IV. Investigations on the Corrosion and the Constitution of Slags. (Untersuchungen über die Verschlackung feuerfester Stoffe. IV. Untersuchungen über die Korrosionkraft und die Konstitution der Eisenhüttenschlacken.) HERMANN SALMANG & FRIEDRICH SCHICK. *Archiv für Eisenhüttenwesen*, Vol. 4, Dec. 1930, pages 299–316; *Stahl und Eisen*, Vol. 50, Dec. 25, 1930, page 1814.

As in the previous investigations (*Archiv für Eisenhüttenwesen*, Vol. 2, 1929, pages 439–447 and Vol. 3, 1929–1930, pages 313–318), the slagging of refractories was studied by melting oxides, binary and ternary silicates and other groups of silicate melts in clay and sillimanite crucibles in the temperature range between 1410° and 1580° C. In all melts, CaO was the strongest base; FeO, MgO and MnO range next. FeO and MnO react as bases, whereas Fe_2O_3 and MnO_2 react as acids, i. e., they do not attack clay and retard the attack of the bases. It is remarkable that alkalis are not strong bases at high temperatures, as is true for low temperatures, because alkaline silicates do not, evidently, dissociate at high temperatures. P_2O_5, as an acid, hinders the attack of bases but readily attacks at higher temperatures when it is present in excess. The 2 formulae which follow hold for basic slags. (Composition in percent of weight; slagging, K, in mm. of dissolved crucible materials.)

$$1410°\ C.:\quad 1.25 \cdot \frac{7\,(CaO) + 7\,(MgO) + 5\,(FeO) + 4\,(MnO)}{(Al_2O_3) + 2\,(SiO_2) + (Fe_2O_3) + 5\,(P_2O_5)}\ \text{mm.}$$

$$1500°\ C.:\quad 1.8 \cdot \frac{7\,(CaO) + 4\,(MgO) + 4\,(FeO) + 3\,(MnO)}{(Al_2O_3) + 2(SiO_2) + 0.5\,(Fe_2O_3) + 2.5\,(P_2O_5) + (TiO_2)}\ \text{mm.}$$

GN(24)

GASES IN METALS (25)

Deoxidation of Copper with the Metallic Deoxidizers, Zinc, Beryllium, Barium, Strontium and Lithium. EARLE E. SCHUMACHER, W. C. ELLIS & JOHN F. ECKEL. *Metals & Alloys*, Vol. 1, Sept. 1930, pages 714–716.

Cathode sheet Cu was melted under charcoal in alundum-lined graphite crucibles heated in an electric resistance furnace, deoxidizers were added after the Cu had been removed from the furnace, the melt was stirred and then poured. In the case of the Cu deoxidized with Ba, Sr or Li, melts of 200 g. were prepared in fused SiO_2 crucibles. Whenever possible the deoxidizer was added as an additional alloy with Cu. Tests were made on wire of 0.104-inch diameter. Properties of Cu deoxidized with Zn: The ultimate strength remains nearly constant while the proportional limit decreases slightly with the increase in Zn content. The elongation in 2 inches increases from 4.5% for tough pitch Cu to 5.5% for the alloy containing 0.097% Zn and continues from this point to 0.377% Zn at an almost constant value. The alloys containing Zn were not embrittled by annealing in H_2 at 800° for one hour. The excess of Zn resulting from the deoxidation of Cu has a comparatively small effect on the conductivity of the Cu. Up to 0.3%, each 0.05% of Zn remaining reduces the conductivity approximately 0.8%. Properties of Cu deoxidized with Be: The ultimate strength increases slightly with the increase of Be content, while the % elongation decreases correspondingly. The alloys containing Be were not embrittled by the H_2 anneal. Each 0.05% of residual Be retained in the metal reduces the conductivity approximately 10%. Properties of Cu deoxidized with Ba and with Sr: In the case of both Ba and Sr only a small quantity of the added element remained in the Cu. The mechanical properties of the hard drawn and annealed wire are, in both cases, not much different from those of tough pitch Cu. The conductivities in the two conditions are generally high. The Cu has high ductility and strength after annealing in H_2. Properties of Cu deoxidized with Li: Li is exceedingly reactive with the oxides ordinarily present in refractories. Cu deoxidized with Li has good mechanical properties. Explanatory data and graphs are given to illustrate the effects of all of the added elements. ESC(25)

Manganese and Silicon as Deoxidizers. EDMUND R. THEWS. *Metal Industry*, London, Vol. 37, Aug. 1, 1930, pages 99–102.

Mn as a deoxidizing agent reacts similarly to P, except that the oxidation product of Mn forms a fluid slag which rises to the surface. On account of its high melting point, Mn cannot be used for deoxidizing purposes in its elementary state. Modern electric melting furnaces reduce production of Cu-Mn alloys to a mere matter of melting and mixing the components. Deoxidizing effects of Cu-Mn alloys exhibit a number of strongly individual features. The less Fe and C in Cu-Mn alloys the more pronounced their deoxidizing power, and the lower the loss by atmospheric oxidation. Compared with P, Mn exhibits a number of serious technical and economic disadvantages. The only distinct advantage of straight Cu-Mn alloys as deoxidizing agents is that small excess of Mn influences mechanical properties of a number of brass and bronze alloys. The deoxidizing action of Si on Cu and Cu alloys is similar to that of P. Its chief disadvantage is that of high melting and volatilization points. Cu-Si is mostly used as deoxidizer for Cu, bronzes and brasses. If added to straight Cu melts, best results are obtained with from 0.75 to 1.00%. Mechanical properties of brass alloys are but little influenced by traces of Si, while if Si added is just sufficient to effect deoxidation, tensile strength and elongation of alloys are improved. Includes several tables. VSP(25)

INSPECTION (26)

Spark Test Determines Metal Characteristics. *Abrasive Industry*, Vol. 11, May 1930, page 29.

Explains the relation of the study of color, form, quantity and nature of sparks to quick information on the kind of metal being ground. (26)

EFFECT OF ELEMENTS ON METALS & ALLOYS (27)

Molybdenum in Steel Industry. *American Metal Market*, Vol. 38, Jan. 9, 1931, pages 8, 9.

One of the features of 1930 in metallurgy was the greater use of molybdenum as an alloying material. Chrome-molybdenum alloy steel is regarded as essential for tubing out of which fuselage for airplanes are fabricated. All nitriding steels contain molybdenum. Nickel-molybdenum steels are used in the roller bearing industry. Plain molybdenum steels are used for some special alloy steel shovels and other uses. Molybdenum is being introduced in the 18% chromium-8% nickel types of steels to the extent of 1–3%, particularly where strength at high temperatures is needed. A special alloy of nickel, molybdenum and iron is unattacked by hydrochloric acid and is being produced as castings and as rolled products, which should find extensive use in the hydrochloric acid industry. WHB(27)

Twenty Alloys for Gray Iron. E. K. SMITH & H. C. AUFDERHAAR. *Iron Age*, Vol. 126, Nov. 27, 1930, pages 1583–1587; Dec. 4, 1930, pages 1688–1693.

Chiefly a discussion of literature published on the subject. In several instances investigations are now under way, and results are not yet available. Al has 3 valuable possibilities in the foundry: (1) addition of not more than 0.10% as softener and deoxidizer; (2) addition up to 0.5% to turn white Fe gray; (3) as corrosion resisting alloy of austenitic type with about 18% Al. Very little information available on the effect of Sb in cast Fe. As up to 0.1% has no deleterious effect. Investigations in progress now indicate that Bi may be used to advantage in some types of cast Fe. B increases hardness and makes metal brittle, preventing formation of graphite. Ca up to 0.2% has no effect on tensile strength, transverse strength, fluidity or shrinkage. Data on Ce in cast Fe is very meager. Use of Cr has many advantages by reason of its low cost and finds many applications. Cr is usually connected with Ni. Up to 2% of Co no useful results have been obtained. Small amounts of Cu readily enter into solution in matrix of cast Fe. Cu confers corrosion resistance to cast Fe. Pb will not alloy with Fe. Little work has been published on Mg. Effect of Mn on cast Fe is fairly well understood. Mo acts as strengthener and hardener of gray Fe. In general Ni acts as a softener. It breaks up carbides, reduces chill and separates out graphitic C. When Si ranges above 5%, character of cast Fe changes and Si may be considered an alloy. Sn seems to have possibilities as a hardener under special circumstances. Action of Ti is that of a deoxidizer and possibly a remover of N. W retards the decomposition of carbides. V increases hardness transverse and tensile strength and resistance to impact. Owing to its rapid oxidation Zn cannot be found in Fe. No definite information is available on Zr. VSP(27)

The Impurities in Lead and Their Influence on the Lead Grain. (Ueber die Zwischensubstanz des Bleis und ihren Einfluss auf Bleikorn.) G. TAMMANN & K. L. DREYER. *Zeitschrift für anorganische und allgemeine Chemie*, Vol. 191, July 7, 1930, pages 65–68.

It is shown that the addition of 0.1% Cu to Pb in the molten state hinders the grain growth on cooling so that the resulting metal has smaller grains and, subsequently, a greater tensile strength. (27)

Influence of Aluminum on Technical Brass Alloys. EDMUND R. THEWS *Canadian Chemistry & Metallurgy*, Vol. 14, Nov. 1930, pages 322–323, 325.

Al represents one of the most useful addition agents when added in the correct proportions and under correct conditions. Alumina is responsible for the misgivings regarding the value of Al in brasses. Al tends: to produce the valuable properties of bronzes; to increase the tensile strength and density; increase resistance to corrosion; and, in small quantities in Zn-rich brass alloys, to create a freedom from Zn vapors. The production of Al-brass castings free from aluminum oxide must be viewed from 3 angles: (1) prevention of the introduction of excessive quantities of oxide in the melt. (2) removal of the oxide from the melt previous to casting and (3) casting in a manner preventing the introduction of aluminum-aluminum oxide skins into the castings. Cu should be deoxidized before the addition of Zn and Al. While the presence of aluminum oxide cannot be completely avoided in the bath, the addition of a small quantity of phosphor-copper directly previous to casting causes the oxide to float and they are easily removed. Bottom-pouring tends to minimize agitation of the bath and the introduction of dross. To secure high-grade Al-brass castings, it is necessary to keep Al-brass out of the brass scrap charged. A brief bibliography is appended. WHB(27)

Investigation of the Effects of Impurities on Copper. Part VII.—The Effect of Antimony on Copper. Part VIII.—The Combined Effect of Antimony and Arsenic on Copper. S. L. ARCHBUTT & W. E. PRYTHERCH (National Physical Laboratory). *Institute of Metals, Advance Copy* No. 546, 1931, 33 pages.

Alloys containing less than 0.02% O were investigated. Those containing up to 0.47% Sb rolled hot, while one with 0.85% Sb was hot short. Annealed ingots containing up to 0.85% Sb could be cold rolled. All alloys containing 0.47% or less Sb could be rolled into thin sheet. Sb increases strength without appreciably affecting ductility. The endurance limit of the annealed 0.47 Sb alloy was 7.8 tons/in.^{2} as compared with 5 or 6 tons/in.^{2} for pure Cu. The softening temperature is raised by Sb, its effect being greater than that of As. The limit of solubility of Sb in solid Cu was determined microscopically as approximately 10%. The addition of As to alloys containing Sb had only slight effect on the properties. All of the alloys had high impact strengths. Contains 9 references. JLG(27)

The Effects of Nickel upon the Mechanical Properties and Micro-Structure of White Heart Malleable Cast Iron. J. V. MURRAY. *Proceedings Staffordshire Iron & Steel Institute*, Vol. 45, 1929–30, pages 40–44.

Specimens of cupola malleable with additions of nickel shot in the ladle were cast in green sand and annealed 6 days, excluding heating up and cooling down. The annealing temperature is not stated. Another series made up in the cupola was similarly treated. Carbon analyses were not given. The data follow:

	Composition					Mechanical Properties		
	Si	*S*	*P*	*Mn*	*Ni*	Tensile Strength lbs./in.²	Elongation % in.2″	Bend Test on 8″ × 1″ × 3/8″ degrees

* British Eng. Stds. Assn. Specification No. 309—Tensile bar 0.564″ diam.

It is concluded that nothing is gained by raising the nickel above 1%; this addition increases the tensile strength to 57,000 lbs./in.², though in the cupola series the elongation and bend were dropped below specification limits. With 1% Ni the usual totally decarburized outside zone is absent, pearlite being present clear to the edge. Nickel retards the breakdown of pearlite during annealing. With over 1% Ni the pearlite becomes troostitic, while with 3%, graphite flakes appear, and the pearlite is again of normal structure. HWG(27)

Use of Bismuth in Fusible Alloys. J. G. THOMPSON. *U. S. Bureau of Standards Circular* No. 388, December 15, 1930, 8 pages, 45 references. Supt. of Documents. 5 cents.

Discussion of composition, melting point and uses of low-melting alloys of Pb, Si, Bi and Cd. The quaternary eutectic is at 70° C. and figures in the literature indicating lower melting points for these alloys (free from Hg) are in error. HWG(27)

Nickel Cast Iron in Theory and Practice. (Nickelgusseisen in Theorie und Praxis.) M. WAEHLERT. *Giesserei*, Vol. 17, Jan. 17, 1930, pages 57–63.

Efforts which have been made to improve cast Fe are discussed. Consideration of the influence of alloy additions; Ni and Ni-Cr; reciprocal effects of these and Si, P and S; raw materials and alloying processes; applications and initial costs. (27)

The Effect of Additions of Small Percentages of Nickel to a Copper-Tin Bronze. C. UPTHEGROVE, G. WILSON & F. N. RHINES (Univ. of Mich.). *Proceedings American Society for Testing Materials*, Vol. 30 Part 2, 1930, pages 512–521.

Includes discussion. Hardness (Rockwell and micro character) and microstructure, but no other properties, were determined on alloys containing 15% Sn, the 85% Cu being partly replaced by 0, 1/4, 1/2, 1, 2, 3, 5 and 10% Ni in chill cast alloys and 0, 1, 2, 3 and 5% in sand cast alloys. The specimens were annealed for 120 hrs. at 800° C. and furnace cooled. The Rockwell hardness rose from around 40 for zero, 1/4 and 1/2% Ni up to about 75 for 3% Ni and then fell to about 60 for 10% Ni. The corresponding changes in the α and δ constituents were followed by the micro character. The micro character indicated that the hardness of both constituents rose to a maximum at 5% Ni, that of the α rising steadily, while that of the δ first fell to 1/2% Ni, and then rose steadily to 5% Ni. Substitution of Ni for Cu leads to the disappearance of α from the eutectoid and the appearance of a dispersed constituent throughout the α-matrix. This dispersion accounts for the increased hardness of the α. (27)

INSTRUMENTS & CONTROLLERS (28)

The Equipment of Heat Control of the Open Hearth Furnaces of the Rasselstein Steel Plant. (Die Wärmetechnische Messanlage an den Siemens-Martin-Oefen der Rasselsteiner Eisenwerke.) K. H. MOLL. *Siemens Zeitschrift*, Vol. 10, Dec. 1930, pages 615–620.

An illustrated description of all instruments for supervising the heat efficiency of the Rasselstein open-hearth plant. All recording instruments are installed in a special supervision room. GN(28)

Color Pyrometry. (Zur Farbpyrometrie.) G. NAESER. *Mitteilungen Kaiser Wilhelm Institut für Eisenforschung*, Vol. 12, 1930, Report 163, pages 299–316; *Stahl und Eisen*, Vol. 50, Dec. 18, 1930, pages 1788–1789.

This is the last installment of Naeser's papers on the color pyrometer. After reviewing the various methods which can be used in measuring temperatures by means of measuring the color of emitters, 2 of these methods were carefully examined. The first method, as previously described (*Stahl und Eisen*, Vol. 49, 1929, pages 464–466), is based on the comparison of colors; the other measures the brightness of the colors. Both methods are described and the suitability investigated and established. Color pyrometer offers large advantages. See also *Metals & Alloys*, Vol. 1, Oct. 1930, page 789. GN(28)

The Influence of Atmosphere, Temperature and Material of Protection Tubes on the Stability of Platinum Thermo-couples. HINNÜBER. *Krupp'sche Monatshefte*, Vol. 11, Sept.–Oct. 1930, 245–251.

This paper corresponds to the publication in *Archiv für Eisenhüttenwesen*, Vol. 3, June 1930, pages 781–785 and in *Stahl und Eisen*, Vol. 50, July 31, 1931, pages 1089–1090. See *Metals & Alloys*, Vol. 1, Oct. 1930, page 789. GN(28)

EFFECT OF TEMPERATURE ON METALS & ALLOYS (29)

Investigations of the Mechanical Strength of Steels and Alloys at High Temperatures. (Etudes sur la Résistance mécanique à chaud des Aciers et Alliages.) A. MICHEL (Etablissements Jacob Holtzer, France). *First Communications of the New International Association for the Testing of Materials*. Group A. Zurich, 1930, pages 85–88.

Very brief reference to French publications in this field. The "limit of sudden elongation without flow" at 450° C. of a steel of about 0.30% C, 0.75% Cr, 2.75% Ni is raised from 27,000 to 38,500 or 52,500 lbs./in.² (depending on heat-treatment) by the addition of 0.33% Mo. HWG(29)

The Effect of Temperature upon the Torsional Modulus of Spring Materials. F. P. ZIMMERLI, W. P. WOOD & G. D. WILSON. *Proceedings American Society for Testing Materials*, Vol. 30, Pt. 2, 1930, pages 350–367.

Includes discussion. See *Metals & Alloys*, Vol. 1, Oct., 1930 page 789. (29)

Factors Affecting the Chilling Properties of Cast Iron. A. L. NORBURY. *Foundry Trade Journal*, Vol. 43, July 17, 1930, pages 44–45.

From a paper presented to the Pan-European Foundry Congress, Liege, June 1930, on behalf of the Institute of British Foundrymen. Chilling properties of cast Fe are largely dependent on its chemical analysis, particularly Si content. But it has been realized that other qualities affect chilling of Fe. Valuable work has been done by Piwowarsky, Hanemann, Bardenheuer and others. Gives results of differences in chilling properties obtained from Fe of same chemical analysis and also results of the effect of total C, Si, Mn and S contents, and mold temperature on chilling properties. VSP(29)

Long Heating Periods at High Temperatures Affect Gray Cast Iron. R. S. MACPHERRAN & H. KRUEGER. *Foundry*, Vol. 58, Oct. 1, 1930, pages 103–106, 111–112.

Cites tests conducted by various investigators. These tests were carried out at temperatures in excess of 1100 or below 850° F. The authors determined the effect of heat on various types of gray cast Fe from 800° to 1100° F., showing changes in combined C, Brinell hardness, tensile and transverse strength. One series was heated to various temperatures for 500 hours intermittently, while the other was heated continuously. Tests showed low tensile strength at elevated temperatures. Best results were obtained from a series containing Cr. Outlines European practice. Tabulates results of investigations. VSP(29)

Hardness of Metallic Alloys at Various Temperatures. (Die Härte der Metallegierungen bei verschiedenen Temperaturen.) V. P. SHISHOKIN & V. AGEJEWA. *Zeitschrift für anorganische und allgemeine Chemie*, Vol. 193, Oct. 21, 1930, pages 237–244.

Hardness determinations were made on binary alloys in which the components do not form chemical compounds: Bi-Sn, Bi-Cd, Pb-Cd, Sn-Cd, Pb-Sn, Sn-Zn, Zn-Cd. In all cases except Pb-Sn, hardness composition curves show a similar course for all systems at all temperatures. Deviations in the case of Pb-Sn alloys are, perhaps, explained by insufficient heat treatment. Breaks in the curves at 2.7% Bi in the Cd–Bi system, at 8.7% and 38% Cd in Cd–Pb, and at 1.7%, 2.9% and 90.9% Pb in Pb–Sn are probably due to the passing of the 2 components into solid solution. In the Cd–Zn, Sn–Zn, and Cd–Sn systems, these breaks are due to eutectoid transformations. The temperature coefficient of hardness of the investigated alloys is greater than the temperature coefficient of the pure metals, and is given by the expression: $\alpha = \frac{\log H_2 - \log H_1}{t_2 - t_1}$. The greatest increase in α is in the alloy Bi-Sn (0.0028 – 0.0017), the smallest in the alloy Pb-Cd (0.0039 – 0.0057) and Zn-Sn (0.0038 –0.0056). Solid solutions of low concentrations are found on both sides in the system Bi–Sn but only on the Pb side in the system Pb–Cd; no solid solutions are found in Zn–Sn. In all the systems except Sn–Cd the highest temperature coefficient of hardness is found in the region of the eutectic. The displacement of the maximum in the Sn–Cd system is probably explained by the presence of a eutectoid point. The magnitude of the temperature coefficient of hardness is apparently not influenced by annealing conditions. (29)

Behavior of Metals at High Temperatures. (Verhalten von metallischen Werkstoffen bei hohen Temperaturen.) H. STÄGER (Switzerland). *First Communications of the New International Association for the Testing of Materials*. Group A. Zurich, 1930, pages 89–96.

Short-time tests and long-time flow tests are given on 15 steels at 400°, 500° and 600° C. Steels containing Mo were superior at the higher temperatures to comparable Cr and Ni Cr steels.

Composition			Creep Limit, lbs./in.²	
C	Mo	Cr	500° C.	600° C.
.25	.41	—	9000	2100
.22	.80	—	10000	2800
.64	1.83	16.0	57000	5500

The Magnetic Properties of Metals at Low Temperatures. (Die Magnetischen Eigenschaften der Metalle bei tiefen Temperaturen.) H. R. WOLTJER. *Metallwirtschaft*, Vol. 8, Nov. 1, 1929, pages 1060–1061.

Contains 15 references. A review of the work of other investigators on paramagnetic, diamagnetic and ferromagnetic metals at temperatures as low as −253° C. CEM(29)

LEACHING (30)

Chemistry of Leaching Bornite. JOHN D. SULLIVAN. *Bureau of Mines Technical Paper* 486, 1931, 20 pages.

Bornite can be leached with ferric sulphate. The rate of dissolution was virtually independent of the strength of the ferric sulphate if enough reagent was present. As ferric salts reduce current efficiency and necessitate higher current densities in electrolytic precipitation it is desirable to keep their concentration as low as possible. If the ferric iron remained constant, the rate of dissolution was independent of acid strength (0.25 to 10%). The rate for 10 to 28 mesh particles was practically identical with that for 100 to 200 mesh mineral. Smaller material was attacked only slightly more rapidly and larger only slightly more slowly. Temperature had a marked effect. Leached particles retained practically their original form. The final particles were composed of sulphur and insoluble material. Sulphuric acid and air will attack bornite more slowly than ferric sulphate. Ferric chloride was more effective than ferric sulphate. AHE(30)

REDUCTION METALLURGY (31)

The Oxidation of Copper during Smelting and the Importance of Oxide Test. (Zur Oxydation des Kupfers bei Flammofenraffination und die Bedeutung der Oxydprobe.) P. SIEBE. *Metall und Erz*, Vol. 27, Nov. 1930, pages 549–557.

Contains 3 references. The nature and amount of impurities in Cu during the oxidation stage of smelting can be determined quickly by microscopic examination. Tests made on samples from smelters and laboratory melts are described. During the oxidation and at the beginning of the reduction period: 1. Long dendrites in the eutectic ground mass indicate high purity of the melt; if round Cu_2O inclusions are present they are always without core. 2. Short dendrites and round Cu_2O inclusions with cores indicate impure melt; the dendrites are shortened by higher Sn content and Sb, As and Pb impurities. 3. As the oxidation progresses the length of the dendrites increases, more in the pure than the impure melts; a coarse fracture indicates long dendrites. 4. The poling process is shown by the appearance of ring shaped Cu_2O inclusions. In hypereutectic test heats: 1. Small amounts of Ni and Sn do not change the structure, but Sb and As tend to ball up the eutectic and shorten the dendrites. 2. Overheating the melt causes the formation of longer dendrites; quicker cooling does not influence the arrangement of the dendrites, but causes finer eutectic separations. 3. Brinell hardness increases with increasing fineness of eutectic. CEM(31)

The Loss of Air Pressure in the Bustle Pipes of the Blast Furnace. (Druckverluste in Hochofenwind-Leitungen.) MARCEL STEFFES. *Stahl und Eisen*, Vol. 50, Nov. 20, 1930, pages 1644–1645; *Revue Technique, Luxembourgeoise*, Vol. 22, Sept–Oct. 1930, pages 99–102.

After determining the loss of air pressure in the bustle pipe of the blast furnace investigated, the hot air pipe of this furnace was completely reconstructed, the inner diameter was increased from 800 to 1000 mm., sharp bends were avoided or at least diminished. The totol loss of pressure, which amounted previously to 15 cm. Hg, was reduced to 6 cm. Hg. A further improvement was accomplished by changing the type of tuyères. A pressure of 1 cm. Hg is equivalent to 35 HP. on the blowers. GN+Ha(31)

Calculation of a Copper Puddling Charge. (Berechnung einer Kupfer-Flammofenbeschickung.) VICTOR TAFEL. *Metall und Erz*, Vol. 27, Jan. 1930, pages 10–11.

Reduction of Metal Oxides by Hydrogen. GUY B. TAYLOR & HOWARD W. STARKWEATHER. *Journal American Chemical Society*, Vol. 52, June 1930, pages 2314–2325.

A new method for studying the rate of reduction of metal oxides at temperatures below 500° C. is described. In this, the volume of H is measured. Ferric oxide gel is reduced to ferroso-ferric oxide at 350 and to metallic Fe at 450°. Ignited ferric oxide is not reduced at an appreciable rate at 350° and goes to metal at 450°. Foreign metal interfaces with iron oxide accelerate the reduction to Fe. Alumina and chromium oxide greatly retard reduction of ferroso-ferric oxide. Ferric oxide gels show the flow phenomenon in H at fairly low temperatures, but not in air or in vacuum. The thermodynamics of ZnO reduction in the presence of Cu has been worked out, giving an explanation in the formation of α-brass. MEH(31)

The Reactions in the Hearth of the Blast Furnace. (Die Vorgänge im Unterofen des Hochofens.) A. WAGNER. *Stahl und Eisen*, Vol. 50, Jan. 30, 1930, pages 122–126. 6 references.

After reviewing the literature on the reactions in the lower part of a blast furnace, the reasons are discussed which lead to a low output of Mn and P in many blast furnaces working on Minette ore. Whereas the amount of indirect reduction in the hearth of the furnace is rather limited and determined by the nature of the charge and the kind of pig iron to be produced, it is quite possible to alter the conditions of combustion in front of the tuyères by installing tuyères which have the shape of a double cone. By using the so-called Venturi-tuyères, an essential increase of output was observed. The Venturi form permits a greater conversion of the velocity of the blast into pressure so that a furnace will take about 15% more volume of blast without the necessity of increasing the blast pressure. The daily output of a blast furnace increased from 891 to 963 tons after the installation of the Venturi-tuyères. GN(31)

Investigations of a Blast Furnace Working on Minette Ore and Using Saar Coke. (Untersuchung eines mit Saarkoks betriebenen Minett-Hochofens.) A. WAGNER & G. BULLE. *Archiv für Eisenhüttenwesen*, Vol. 3, Dec. 1929, pages 391–395; *Stahl und Eisen*, Vol. 49, Dec. 26, 1929, pages 1860–1861.

The authors give the results of an investigation of the reduction process of the ore during its descent through the blast furnace, the conditions of the combustion of coke and the calculation of a heat balance. Gas samples were taken in the shaft in 3 levels: 6.15 m., 9.4 m. and 12.2 m. above the zone of the tuyères. The discrepancies of the individual gas analyses, however, are too great to allow drawing reliable conclusions on indirect reduction and C segregation. The only reliable conclusion is that, in the lower zones of the furnace, very large qauntities of CO and H must be present. This is probably due to the quick descent of large lumps of ore which do not become thoroughly roasted unless they reach the lower parts of the shaft. Only about $8^1/_2$% of the coke is used for the reduction of the ore to Fe, but approximately 4% for the decomposition of the moisture. About 81% of the coke reaches the zone of the tuyères unburnt. Information is given on the composition of samples of the charge drawn from the shaft as well as on the composition of slag. Temperatures observed in the furnace vary widely. GN(31)

Electrothermic Zinc. A. WALTER. *American Electrochemical Society, Preprint* 59–4, April 1931 Meeting, 4 pages.

The development of electrothermic zinc during the past 30 years is briefly reviewed, emphasizing in particular the many difficulties to be overcome before the process became commercial. The smelting is carried out in an arc furnace of the Heroult type. The operation is continuous and comparatively simple. The zinc vapors pass out of the furnace and into a condenser, from which the zinc is tapped at regular intervals. The crude zinc (93–95% Zn) thus produced is refined by resublimation in a separate electric furnace. The final product averages 99.85% Zn. The process outlined is applicable to all kinds of zinc ores, and high recoveries of accompanying metals such as Cu, Pb, Au and Ag are possible. The total electric energy consumption amounts to 5600 kwh./1000 kg. of 99.85% slab zinc. (31)

Iron Ores Beneficated by Direct Reduction and Concentration. GEORGE B. WATERHOUSE. *Iron Age*, Vol. 127, Jan. 8, 1931, pages 161–162.

Presents some of the results obtained by W. H. Smith on the benefication of low content Fe ores by the sponge iron process, thus to render them equal to high grade ores. The process consists in low temperature reduction of the ore, followed by crushing and magnetic concentration. Concentration will remove from 20 to 90% of the gangue. Gives table showing results obtained on various ores from U. S. and foreign countries. VSP(31)

Notes on the History of Furnace Linings. E. G. WHELPLEY (Shea-Whelpley Construction Co.). *Blast Furnace & Steel Plant*, Vol. 18, Feb. 1930, pages 288–290.

Deals with the development of linings for blast-furnaces, and discusses the place of the furnace building contractor in relation to present plant conditions. MS(31)

Recovery of Zinc from Ferrite Compounds in the Electrolytic Zinc Process. G. L. OLDRIGHT & D. P. NICONOFF. Department of Mining and Metallurgical Research, University of Utah, *Technical Paper* 6, 1929, 45 pages.

Zinc ferrite formation increased with increasing time, temperature and fineness. Iron in zinc ferrite was more readily soluble than when present in Fe_2O_3. Replacement of ZnO in ferrite by other bases such as CaO and MgO is possible, but not practical. Zinc ferrite was readily decomposed by treatment with reducing agents at elevated temperatures; zinc was then soluble in ammonia or sulphuric acid. High concentrations of reducing gases make the iron soluble in sulphuric acid. Carbon will reduce ferrites at 800°. Pure CO should not be used below 600° as CO_2 is needed at low temperatures to prevent its decomposition to CO_2 and C. The best procedure was treatment for 2 hours at 550° with CO_2 containing 35–50% CO. This makes 80% of the zinc and 39% of the iron soluble in sulphuric acid. To make more zinc soluble, higher proportions of iron were dissolved. The rate of decomposition of ferrite with reducing agents, as well as its rate of dissolution in sulphuric acid, hydrochloric acid, and nitric acid depend upon the temperature and time of preparation of the ferrite. By giving refractory ferrite a preliminary low-temperature roast, the subsequent rate of reduction can be increased AHE(31)

Washing Mesabi Iron Ores. S. A. MAHON & T. B. COUNSELMAN. *Engineering & Mining Journal*, Vol. 130, Nov. 24, 1930, pages 519–521.

An abstract of a paper read at a recent meeting of the Lake Superior Mining Institute. Changes made over the original flowsheet of the mine involve: (1) the replacement of the turbos and tables with bowl classification, (2) the introduction of secondary crushing for further liberation of silica from the coarser sizes, and (3) the tendency toward the use of abrasive screening on much of the material formerly treated in the 25-ft. log washers. Several tables, and flowsheets for the original process, for bowl classification and secondary crushing and with the Dorr washer are shown. WHB(31)

Disintegration of Blast Furnace Slag. (Ueber den Zerfall der Hochofenschlacke). F. HARTMANN & A. LANGE. *Archiv für Eisenhüttenwesen*, Vol. 3, April 1930, pages 615–624; *Stahl und Eisen*, Vol. 50, April 17, 1930, pages 517–518.

Following a survey of the literature on the subject, the authors give the results of their own experiments to determine the influence of composition and heat treatment on the composition of slag. See also *Metals & Alloys*, Vol. 2, Feb. 1931, pages 51. GN(31)

NON-METALLIC COATINGS FOR METALS & ALLOYS (32)

Use of Burn-Off Ovens in Preparing Metal Surfaces for Baked Finishes. WILLIAM J. MISKELLA. *Fuels & Furnaces*, Vol. 8, April 1930, pages 531–536.

Burn-off process for removing oil and grease is used for large articles and where there are seams and folds. Automotive parts are usually subjected to a temperature of 600°–700° F. for 3 or 4 min., and are wiped while hot. For removing paint and varnish, the temperature is about 700° F. Other methods of cleaning metal parts are by the use of alkaline solutions, acid dips, and organic solvents. Gives examples of various cleaning operations. MS(32)

Applying Baked Color Finishes to Metal Surfaces. WILLIAM J. MISKELLA. *Iron Trade Review*, Vol. 86, April 3, 1930, pages 71–74.

Describes methods used in japanning and enameling. The finishes are applied by dipping or spraying and are dried in ovens, the time varying from 15 min. to 4 hrs. Elaborate handling systems have been installed in many plants, making the process almost completely automatic. MS(32)

Vitreous Enameling Cast Iron. C. D. CLAWSON (Chicago Vitreous Enamel Product Co.). *American Machinist*, Vol. 72, Oct. 9, 1930, pages 579–581.

Deals largely with the application of enamel by the dry and the wet process. Some material on the finishing and cleaning of the cast iron. RHP(32)

Enameling Industry Solves Problem of Continuous Burning. *Iron Trade Review*, Vol. 86, Jan. 2, 1930, page 30.

Several authorities give views on progress made during 1929 in pickling and enameling. MS(32)

Recirculating and Remote Heater Type Ovens. WILLIAM J. MISKELLA (Finishing Research Laboratories, Inc.). *Fuels & Furnaces*, Vol. 8, Feb. 1930, pages 255–256, 262.

Relates to japanning ovens. Discusses construction and operating features. MS(32)

Development in the Use of Ovens for Baked Finishes. WILLIAM J. MISKELLA. *Fuels & Furnaces*, Vol. 8, June 1930, pages 821–822.

New synthetic undercoat for application under lacquer finishes is sprayed on and dries in 15 min. Surfacer is then applied and both are baked at once. A baking process has been developed, wherein 2 coats of japan, or any other finishing material, are applied in such a way as to require only one bake. MS(32)

Japanning Oven Construction. WILLIAM J. MISKELLA. *Fuels & Furnaces*, Vol. 8, May 1930, pages 679–682.

Discusses some important features such as selection of heating medium, insulation, door construction, ventilation, roof, load supports, and corner design. MS(32)

Use of Automatic Spray Equipment. WILLIAM J. MISKELLA (Finishing Research Laboratories, Inc.). *Metal Cleaning & Finishing*, Vol. 2, April 1930, pages 335–338. Discusses applications, uses, and advantages of automatic spray equipment for finishing metal parts. MS(32)

Selection of Japanning Ovens. WILLIAM J. MISKELLA. *Fuels & Furnaces*, Vol. 8, Jan. 1930, pages 115–118.

Discussion of the advisability of systematic planning. MS(32)

Tumbling and Flowing Methods of Applying Finishing Materials. WILLIAM J. MISKELLA (Finishing Research Laboratories, Inc.). *Metal Cleaning & Finishing*, Vol. 2, Feb. 1930, pages 145–148, 160.

Traces development of the tumbling and flowing methods and points out advantages of each. Tumbling is used mostly for small objects. It is a very simple method, and has the great advantage, when the tilted barrel is used, of allowing samples to be easily examined without stopping the barrel. The flowing method is about cleanest method of applying finishes. MS(32)

Important Features Regarding the Installation and Operation of Japanning Ovens. WILLIAM J. MISKELLA. *Fuels & Furnaces*, Vol. 8, March 1930, pages 375–378.

Discussion of location of japanning ovens, and their accessibility, safety of operation, ventilation, heating systems, and cleaning. Based on a report of a committee of engineers of the National Fire Protection Association, completed Jan. 16, 1930. MS(32)

Blistering Tendency of Some Cast Irons when Enameled. A. I. KRYNITSKY & W. N. HARRISON. *Transactions & Bulletin, American Foundrymen's Association*, Vol. 1, Aug. 1930, pages 332–372.

Blistering resulting from gas entrapped in the enamel may arise from sponginess of metal, from method of application of enamel and from a very thin surface skin or micro chill on the cast iron. The latter may break down during the process into temper carbon which oxidizes easily. Blistering may be overcome by making the chill either very stable or by removing it entirely with graphitizing agents. Practical remedies are to deep sand blast or to "burn out" the casting. See also *Metals & Alloys*, Vol. 1, Sept. 1930, page 742. CHL(32)

Finishes on the Metal Parts of Telephone Apparatus. H. G. ARLT. *Bell Laboratories Record*, Vol. 9, Dec. 1930, pages 175–179.

At the present time some hundred standard metal finishes are being used on telephone apparatus parts. This paper discusses them and their purposes. MFB(32)

Continuous Enameling Furnace Is Heated Electrically. J. D. KNOX. *Iron Trade Review*, Vol. 86, April 10, 1930, pages 65–67.

Describes equipment and operations of the Mullins Mfg. Co., Salem, Ohio, for vitreous enameling of washing machine tubs. MS(32)

Paint Failure Diagnosis. ROBERT JOB. *Metal Cleaning & Finishing*, Vol. 2, June 1930, page 527.

Abstract of paper read before the American Society for Testing Materials. MS(32)

Testing Lacquers in the Plating Shop R. V. KIRK. *Brass World*, Vol. 26, Nov. 1930, pages 296–297.

A suggestion to the plater who uses lacquer; means by which he may in a quick and empirical, yet practical way, test and evaluate the many lacquers offered for his use. Simple tests for showing the characteristic properties of lacquers are outlined. WHB(32)

Wanted—Instructor

Instructor in industrial chemistry, applied metallurgy, metallography, with at least five years' industrial experience. Must be mechanically inclined and trained. Must have personality needed for successful teaching. Salary to start, $2000 for ten months. Apply only by letter giving full information. Location, New England. Address METALS & ALLOYS, 3619 Forbes Street, Pittsburgh, Pa.

MANUFACTURERS' LITERATURE REVIEWS

In this department we each month list the catalogs and other printed matter issued by manufacturers. Unless otherwise noted, any of the items listed may be secured free upon application to the issuing firm. Manufacturers who have not yet sent in their printed matter are invited to do so.

601 **Electrical Resistance Measurements.**—Catalog No. 40 of the Leeds & Northrup Co., 4901 Stenton Ave., Philadelphia, Pa., lists instruments intended specifically for measuring the resistance of electrical conductors, such as standard resistors, Wheatstone bridges, Kelvin bridges, etc. Some other closely related instruments are also listed.

602 **Nickel-Clad Steel.**—The Lukens Steel Co., Coatesville, Pa., has sent out a folder recently announcing their Nickel-Clad Steel Plate. In the hot rolling process the pure nickel is actually welded to the steel. The product is available in all sizes of plates $^{3}/_{16}$ inches thick and heavier, and in two grades in which the solid nickel is 10% or 20% of the thickness of the Nickel-Clad Steel Plate. The company has also prepared a reprint of an article "Nickel-Clad Steel Plate Work" which appeared in *Mining and Metallurgy*, Feb. 1931.

603 **Electric Furnaces.**—A recent publication of the Process Engineering & Equipment Corp., Attleboro, Mass., is a 12-page booklet describing several of their special atmosphere electric furnaces which keeps air from the material while it is being heat treated and cooled. The work is removed bright and clean and ready for succeeding operations or finishing.

604 **Stainless Alloy Steels.**—To the development and production of ferritic chromium-alloy steels and austenitic chromium-nickel steels, five of the subsidiary manufacturing companies of the U. S. Steel Corporation have applied the resources of their respective organizations and research departments. A booklet descriptive of the properties of the alloys will be sent by the American Sheet & Tin Plate Co., Frick Building, Pittsburgh, Pa.

605 **Speed Reducers.**—A leaflet has been prepared by Gears & Forgings, Inc., Cleveland, Ohio, which describes their planetary, worm gear, and herringbone speed reducers. For more detailed information on planetary speed reducers write for Bulletin B. Bulletin C is devoted to worm gear speed reducers.

606 **Sand Testing Equipment.**—One of the most attractive catalogs which has come to our desk recently is Catalog No. 102 of the Harry W. Dietert Co., 676 W. Grand Blvd., Detroit, Mich. Sieves to determine the fineness of sand are illustrated, as well as instruments to gage its strength, permeability and bonding value. The section containing practical and technical data should be very useful.

607 **Arc Welding of Structural Steel.**—The Westinghouse Company is a pioneer in the use of arc welding for the construction of buildings and bridges, having begun in 1926 with several small buildings at their plant in East Pittsburgh and a five-story building at Sharon, Pa. They have just published a most interesting and valuable booklet with the above title, which contains chapters on the strength of welded joints, the inspection of welds, and an outline for estimating the cost of welded construction. Westinghouse Electric & Mfg. Co., East Pittsburgh, Pa.

608 **Arc Welding Structural Steel.**—Another interesting booklet on this subject is gotten out by the General Electric Co., Schenectady, N. Y. After a brief historical sketch of welding in the fabrication of steel structures, there is a short discussion of such parts of the construction as trusses, columns, beams and girders. It is probable that in the near future all building codes will permit welded structures.

609 **Springs.**—In spring design, unsatisfactory cut-and-try methods can often be obviated most readily by the use of a chart, which within its range of application gives its answer immediately or with a minimum amount of computation. Such a chart is presented on pages 4 and 5 of the April issue of Mainspring, published by the Wallace Barnes Co., Bristol, Conn. As always, in this publication, the clever illustrations add not a little to its attractiveness.

610 **Furnaces.**—The W. S. Rockwell Company has developed several types of carburizing furnaces. The rotary type, either electric or fuel, is described in their leaflet No. 296. The counterflow and straight line type continuous furnace is illustrated in leaflet No. 289, while No. 295 is devoted to the enclosed front type of furnace. These leaflets are punched so that they can be put in a binder for easy reference. W. S. Rockwell Co., 50 Church St., New York, N. Y.

611 **Alloys.**—A rather unusual color scheme catches the eye in the Index of "Alpro" Standard and Special Alloys prepared by Alloys & Products, Inc., Oak Point Avenue, New York, N. Y. The alloys are arranged in groups, each one classified as to purpose, with a cross index, classifying them according to their principal constituents, which makes this a valuable piece of literature to have on hand.

612 **The Homo Method.**—This is a highly accurate, automatic way of tempering large quantities of tools or production parts, and of securing an extremely uniform temper. It is used for needles, springs, saws, drills, etc., and for heat-treating various non-ferrous metals. Catalog No. 93 of the Leeds & Northrup Co., 4901 Stenton Ave., Philadelphia, Pa., goes into the process in great detail and shows a number of installations of the furnaces.

613 **Indium.**—A short paragraph on this rare metal is only one of the several interesting articles in the May issue of the Industrial Bulletin put out by Arthur D. Little, Inc., Cambridge, Mass. This periodical always has up-to-the-minute information on timely subjects.

614 **Recording Instruments.**—Bulletin No. 380 of the Bristol Company, Waterbury, Conn., is intended to give some idea in regard to the very complete line of Bristol's instruments for recording, indicating and controlling. It does not include prices of the instruments which are illustrated but it emphasizes the simplicity of principle and construction which features them.

615 **Laboratory Equipment.**—"Electrify Your Laboratory" is the keynote of Bulletin 31A of the Precision Scientific Co., 1736 N. Springfield Ave., Chicago, Ill. Electric heaters for all laboratory operations in which gas is ordinarily used are illustrated, from special heaters for Kjeldahl flasks to heaters to replace the usual Bunsen burner.

616 **Spectrum Analysis in Mineralogy.**—A 52-page booklet with this title has been written by A. A. Fitch for Adam Hilger, Ltd., 24 Rochester Place, Camden Road, London, England. Some of the chapter headings which will indicate the scope of the book are: "Technique of Spectrum Analysis; Qualitative and Quantitative Analysis of Minerals; Analysis of Rocks, Meteorites, and Natural Waters; X-Ray Spectrum Analysis of Minerals. A nominal charge of 1s. 11d. is made for the book.

617 **Cadmium Plating.**—Udylite's Relation to the Automotive Industry is the feature article of the May 1931 issue of The Udylite News, 3220 Bellevue Ave., Detroit, Mich. Numerous parts of automobiles are continually subjected to rust and corrosion and can be protected by Udylite plating.

618 **Permabrite.**—A new high strength, light weight aluminum alloy has been developed by the Apex Smelting Company, 2554 Fillmore St., Chicago, Ill. Their Bulletin No. 1 gives the mechanical and physical properties of this new alloy and suggests some uses for it.

619 **Electric Resistors.**—Bulletin No. 6 of Ryan, Scully & Co., Philadelphia, Pa., gives a full description of their electric furnace metallic resistors, showing their adaptability to new and old furnace installations, and their general construction features. Bulletin No. 9 of the same company is devoted to their electric pot type furnaces which are used in heat treating operations which demand a close accuracy of heat penetration and an entire elimination of surface scale.

620 **Nickel and Monel Metal.**—The International Nickel Co., 67 Wall Street, New York, N. Y., has published a convenient list of their literature for those who are interested in securing data on the properties and uses of Monel metal and nickel.

621 **Tubular Electric Immersion Heaters.**—Bulletin No. 250 of H. O. Swoboda, Inc., 3400 Forbes St., Pittsburgh, Pa., is a supplement to their various publications on large melting and coating tanks for asphalts, tars, oils, varnishes and similar viscous substances. It points out the advantages of the tubular electric over the tubular fluid immersion heaters.

622 **Electric Heating Elements and Units.**—Leaflet TA-30 of the Harold E. Trent Co., 618 N. 54th St., Philadelphia, Pa., gives a short descripton of their strip, tubular and ring heating units and includes a price list.

623 **Hydrogen Ion Potentiometer.**—It is the purpose of Bulletin 766 of the Leeds & Northrup Co., 4901 Stenton Ave., Philadelphia, Pa., to describe a potentiometer sufficiently accurate for all general laboratory work and even for most research involving determination of hydrogen ion concentration, while at the same time it is sufficiently convenient for routine work.

624 **Carboloy.**—The purpose of this publication is to disseminate all the news on what is being done with the product by that name so that users may know what they can expect from their own applications of Carboloy tools. The Feb.-Apr. issue has several interesting uses of such tools and two data sheets which should be convenient. Carboloy, 2481 East Grand Boulevard, Detroit, Mich.

625 **Oil Burners.**—Ryan, Scully & Co. burner equipment meet the wide diversity of requirements for low pressure air atomization and accurately fit in with automatic combustion and temperature control systems. Type A, for general combustion conditions, Type B, for special minimum capacities, Type C, for heavy oil and preheated air, are described in their Bulletin No. 2. Ryan, Scully & Co., 3711 Wissahickon Ave., Philadelphia, Pa.

626 **Furnaces.**—The Surface Combustion Corporation, Toledo, Ohio, has prepared a new folder about their furnaces for carburizing and hardening auto fan shafts with the utmost in economy, uniformity of quality and reliability. The furnaces are described in detail and performance data is given.

627 **Material Handling.**—The Link-Belt Company, 910 S. Michigan Ave., Chicago, Ill., is preparing a series of data sheets on Material Handling & Power Transmission Data, one to be issued each month. These will cover important phases of these subjects about which little has been published. Data sheet No. 1 is entitled "Belt Conveyor Trajectory Chart and Data."

628 **Amsco Bulletin.**—The feature article in the May issue of this periodical is "A Trip Through South America" written by an engineer of the American Manganese Steel Company, and a number of minor articles show various applications of their products. St. Louis, Mo.

CURRENT METALLURGICAL LITERATURE ABSTRACTS OF METALS & ALLOYS

PUBLISHED MONTHLY BY THE CHEMICAL CATALOG COMPANY, INC.

419 Fourth Ave., New York

Editorial and Advertising Offices: 3619 Forbes Street, Pittsburgh, Pa.

Annual Subscriptions: U. S., Possessions, Mexico and Cuba, $3.00; Canada, $3.50; Other Countries, $4.00; Single copies, 40¢.

Copyright, 1931, by The Chemical Catalog Company, Inc. All rights reserved.

Note. The September issue of METALS & ALLOYS will be Vol. 2, No. 3. For purposes of binding and filing, these monthly bulletins may be considered as Vol. 2, No. 2a, 2b, etc

These abstracts are not critical, but merely review developments. The classification number at the end of each abstract will be of assistance in mounting them on filing cards.

Negative print photostats of the original articles abstracted below can be obtained at 35 cents per page, plus 10 cents for mailing first class.
The remittance should accompany the order.
Book Reviews are included below and marked by -B-

CONTENTS—JULY 1931

PATENT SERVICE

Until we resume regular publication in September, the service rendered by the Patent Department of METALS & ALLOYS will be carried on by Mr. W. M. Corse, 810 Eighteenth Street, Washington, D. C., who can supply copies of United States and foreign patents and translations at reasonable costs.

GENERAL (0)

Ideal and Practical Relations between Elasticity and Plasticity, Tenacity and Brittleness. (Begriffliche und prüfmethodische Beziehung zwischen Elastizität und Plastizität, Zähigkeit und Sprödigkeit.) A. SCHOB. (Materialprüfungsamt, Berlin.) *First Communications of the New International Association for Testing Materials*, 1930, Group D, pages 56–62, 2 figures, 31 references.

States definitions for these properties and gives annotated bibliography. HWG(0)

Physical Chemistry of Metallurgical Reactions. A Manual of Theoretical Metallurgy. (Physikalische Chemie der metallurgischen Reaktionen. Ein Leitfaden der theoretischen Hüttenkunde.) FRANZ SAUERWALD. Julius Springer Verlag, Berlin, 1930. Paper, 6 1/2 × 9 1/2 inches, 142 pages. Price 15 RM.

This book is divided into 3 parts, which will be considered in order. Part 1 is a review of the quantitative treatment of chemical reactions. In 30 pages the author skims over the following fundamental theoretical subjects: homogeneous equilibrium and the law of mass action; heterogeneous equilibrium from the standpoint of the Nernst partition law and the phase rule; chemical affinity and the first, second, and third laws of thermodynamics; reaction velocity, both homogeneous and heterogeneous. The treatment of these important concepts is obviously quite superficial and can be considered as little more than a listing of the basic laws and equations which are of particular importance to the metallurgist. The author uses Nernst thermodynamic notation and "chemical constants," which is unfortunate in the light of the more concise and accurate treatment as developed by G. N. Lewis and his collaborators.

Part 2 is a discussion of fundamental metallurgical reactions. Two component systems with gas phase are considered first. Metal-oxygen systems are presented for the metals: Ag, Cu, Pb, Cd, Ni, and Fe. Numerous references are quoted and equilibrium data are presented, with a discussion of the thermodynamics of these reactions. Both P-T and C-T diagrams are included where data are available.

Metal-sulphur systems follow, including the metals: Ag, Pb, Ni, Fe, and Cu. This discussion is brief, since experimental data are meager.

Three component reduction equilibria are discussed for systems of the type: metal-oxygen-hydrogen, metal-carbon-oxygen, metal-sulphur-oxygen. Experimental methods are briefly indicated and the more important equilibria are then discussed in some detail. Six pages are devoted to the various equilibria involved in the combinations, iron-iron oxides-CO/CO_2-C, etc. The work of Maier and Ralston on the reaction $ZnO + CO = Zn + CO_2$ is presented. The equilibria in the system Pb–S–O are included in this chapter along with other less important reactions. The thermodynamic treatment of the data for these reactions is far from satisfactory. No attempt is made to express either equilibrium constants or free energies as a function of the temperature, even when such equations have been previously developed, as in the excellent work of Maier and Ralston mentioned above.

Part 3 is a brief discussion of some applications of physical chemistry to technical metallurgical processes. This chapter is mainly qualitative in character. The more recent experimental studies of blast furnace reactions and the investigations of open-hearth reactions by Herty, Schenk, and others are reviewed. The Ag-Pb-Zn ternary diagram and its application in the Parkes Process are discussed.

It is the opinion of the reviewer that this book should be of considerable interest to the modern metallurgist, if for no other reason than that it points out the possibilities of physical chemical treatment of metallurgical reactions. Unfortunately the development of the theory is too brief to be of use to anyone not already well versed in the subject. The unsatisfactory thermodynamic treatment in this book can be contrasted with the concise treatment employed in the recent metallurgical publications of the Bureau of Mines by Dean, Davis, Maier, Prescott, and others.—Harry Seltz (0)-B-

PROPERTIES OF METALS (1)

Structure and Life of Metals. (Bau und Leben der Metalle.) P. LUDWIK. *Metallwirtschaft*, Vol. 9, Feb. 7, 1930, pages 129–133.

Lecture before the Gewerbeverein in Vienna. The author gives a general description of atomic structure, crystal formation, lattice construction, inter and intra crystalline fracture, crystal growth and refinement, recrystallization, solid solutions. He gives as illustrations the difference between the diamond and graphite, structure of aluminum alloys, overheating of steel, cold working and recrystallization of brass, carburizing and hardening of steel, and the aging of Al alloys. He contends that metals are not dead, but that, similar to plants, they have life, as they grow, combine, divide and regenerate. CEM(1)

The Physical Properties of Rhenium. (Die Physikalischen Eigenschaften des Rheniums.) C. AGTE, H. ALERTHUM, K. BECKER, G. HEYNE & K. MOERS. *Naturwissenschaften*, Vol. 19, Jan. 30, 1931, pages 108–109.

Crystal structure: close-packed hexagonal, having the following lattice constants, a = 2.765 A. U., c = 4.470 A. U., c/a = 1.616. *Melting point:* 3440° ± 50° absolute. *Mechanical properties:* density, measured on a sintered sample, 20.9 (calculated from X-ray data, 21.4—from this the atomic weight, 186.31 ± 0.02, has been obtained); tensile strength, 50.6 kg./mm.²; percentage elongation, 24. *Electrical properties:* electrical resistivity = 0.21×10^{-4} ohm-cm. at room temperature; temperature coefficient of resistivity between 0° C. and 100° C. = 3.11×10^{-3} and between 0° C. and 2710° C. = 1.98×10^{-3}; electron emission: measurements of the electron emission between 1900° and 2700° absolute give for the constants in Richardson's emission formula ($i = AT^2 \times e^{-b/T}$) the following values:

$$A = 200 \times \frac{\text{Amp.}}{\text{cm.}^2 \times \text{Grad.}^2} \text{ and } b = 59{,}500.$$

OWE(1)

The Heat Capacities at Low Temperatures of Antimony, Antimony Trioxide, Antimony Tetroxide and Antimony Pentoxide. C. TRAVIS ANDERSON. *Journal American Chemical Society*, Vol. 52, July 1930, pages 2712–2720.

The heat capacities of antimony and its oxides have been determined and their entropies calculated for the range 60 to 300° K. Heat of formation of the trioxide has been calculated. MEH(1)

The Heat Capacities of Bismuth and Bismuth Trioxide at Low Temperatures. C. TRAVIS ANDERSON. *Journal American Chemical Society*, Vol. 52, July 1930, pages 2720–2723.

The heat capacities of bismuth and its trioxide have been determined from 60–300° K., and their corresponding entropies calculated. The free energy of the oxide has also been calculated. MEH(1)

Some Properties of Metallic Cadmium. G. D. PRESTON (National Physical Laboratory). *Institute of Metals, Advance Copy* No. 556, 1931, 32 pages.

Hardness and tensile values of rolled Cd show that the temperature of working has a pronounced effect on these properties. In ordinary tests the worked Cd appeared to be stronger than the cast, but the conditions were reversed in the long-time ball test. Material in the cold rolled condition was completely recrystallized. In such material appreciable grain growth was found after 5 years. No evidence was found of an allotropic transformation. By X-ray examination the parameter of the unit cell was found to be a = 2.9724 ± 0.0005 A. U., with an axial ratio of 1.8854 ± 0.0005. In cold rolled Cd the 10.1 plane tends to lie on the surface, and the normal to the 00.1 plane is inclined at about 65° to the normal to the sheet. In hot rolled sheet another preferred orientation is found. 17 references. JLG(1)

The Vapor Pressure of Sodium. Low Pressure Measurements with the Absolute Manometer. WORTH H. RODEBUSH & WM. F. HENRY. *Journal American Chemical Society*, Vol. 52, Aug. 1930, pages 3159–3161.

Vapor pressure of sodium between 396.5° and 263.0° C. are given. At the former temperature the vapor pressure equals 0.3025 mm. MEH(1)

The Economic Significance of Zirconium and Its Compounds. J. F. CORRIGAN. *Industrial Chemist*, Vol. 7, Mar. 1931, pages 97–100.

A good review; 12 references. Sources of Zr are discussed and its minerals listed. Zr is now obtained by alumino-thermic reduction 99.5% pure. Earlier methods of production are described. Properties of Zr: a steel-gray metal capable of taking a high polish; does not rust or tarnish; melts at approx. 1600° C.; resembles Fe as an electrical conductor; scratches glass; it readily combines with O_2, H_2, N_2, C, Si, and B; it forms alloys with the ferrous metals and with Ag, Al, Mg, and others, but not with Sn, Pb, the alkalies, or the alkaline earths; it reduces SiO_2, TiO_2, and B_2O_3 at high temperatures. The nitrides of Zr give off NH_3 under certain conditions when treated with H_2 or water, suggesting a use for the metal in nitrogen-fixation. Zr steels are very tough. Ferro-zirconium is obtained with a Zr content ranging between 40 and 90%. A well-known alloy of Zr and Ni is "Cooperite." An alloy containing 65% Zr, 26% Fe, 7.7% Al and 0.12% Ti is very resistant to chemicals, takes a high polish, is very malleable, and may find a use in light filaments. ZrO_2 melts at 2900° C., has a low thermal and electrical conductivity, low coefficient of expansion, and very low porosity; it makes an excellent refractory, and is also used in enamels. MPB(1)

The Optical Determination of High Metallurgical Temperatures. The Melting Point of Fe. C. H. M. JENKINS & MARIE L. V. GAYLER. *Proceedings Royal Society*, London, Vol. 129A, Sept. 3, 1930, pages 91–114.

The melting point of Fe has been determined by 2 methods. In one a closed refractory tube is immersed in the center of a mass of metal to serve as a black body enclosure for sighting an optical pyrometer. In the other a bubble is blown down into a surface of metal. The pyrometer was calibrated by observing the E.M.F. of Pd thermocouple in a black body enclosure. The m. p. of Pd (1555° C.) is indicated by the breaking of the metallic circuit, and over a further temperature range by means of the sector method, using the m. p. of Au (1063° C.) as the other fixed temperature. The m. p. of Fe was found to be 1527° ± 3° C. Refractories were made of hard pure alumina. Difficulties were also encountered in that metal vapors penetrated the refractories and emitted radiations to the pyrometer on condensation, but this difficulty was overcome by ventilation with H_2. HCD(1)

The Technical Preparation of Dvi-Manganese. I. G. F. DRUCE. *Industrial Chemist*, Vol. 7, Feb. 1931, pages 75 and 79.

Dvi-manganese or rhenium, atomic number 75, was discovered in 1925. It occurs in crude manganese salts and in some molybdenum preparations, but always in very small amounts. Two processes patented by Germans for preparing (1) nearly pure metal and (2) potassium perrhenate, are described. About 120 kg. of the potassium salt are at present available. Rhenium promises to afford a new catalyst, and its salts may find uses as reagents for potassium. No other applications have yet been found. 6 references. MPB(1)

An Allotropic Transformation of Calcium in the Solid State. (Sur une Transformation Allotropique du Calcium à l'État Solide.) E. RINCK. *Comptes Rendus de L'Académie des Sciences*, Vol. 192, Feb. 16, 1931, pages 421–423.

Heating and cooling curves of calcium show an inversion at 450° C. A study of this phenomenon has shown that calcium exists in two allotropic varieties—a form α, stable at temperatures below 450° C., and a form β, stable between 450° and 850° C., the melting point of pure calcium. Measurements of the electrical resistivity of calcium are given, and values for the coefficient of electrical resistivity are quoted. Rinck was unable to retain the β-phase by quenching from temperatures above the transformation point. OWE(1)

The Measurement of the True Specific Heat of Solid and Liquid Metals at High Temperatures. (Ueber die Messung wahrer spezifischer Wärmen fester und flüssiger Metalle bei hohen Temperaturen.) H. SEEKAMP. *Zeitschrift für anorganische und allgemeine Chemie*, Vol. 195, Feb. 7, 1931, pages 345–365.

The author describes a process for the measurement of the true specific heat in which a tungsten spiral is employed as the source of energy. Complete details of the method of supporting the spiral within the sample of metal to be investigated are given, the article being accompanied by 4 diagrams describing the apparatus used and the electrical equipment employed in connection with the experiments. Particulars are given of the results of experiments on Cu, Al, and Mg, the true specific heats of which were measured in the solid state. Curves are given showing the relationship between the results and those of previous workers in this field. The second part of the paper deals with the application of this method to the investigation of liquid metals. In this case, the tungsten spiral is protected by means of a porcelain sleeve. Measurements of the true specific heats of solid and of liquid Th were made from the range of 18° to 500° C. It is shown that Th undergoes a transformation at the point of 226.7° C., the heat of transformation amounting to 98 cal./g.-atom. OWE(1)

Cadmium. *Chemical Engineering & Mining Review*, Vol. 23, Jan. 5, 1931, pages 145–146.

The properties, sources, and uses of Cd are discussed. In Australia it has been found that an alloy containing 96.7% Cd, 3.1% Cu, and 0.1% Mg has outstanding qualities as a bearing metal. The physical properties of this alloy are compared with those of a commercial white metal containing 88% Sn, 9% Sb, and 3% Cu. WHB(1)

The Independence of the Hardness and the Hydrogen Content of Electrolytic Metals. (Sur l'Independance de la durete et de la Teneur en Hydrogene des Metaux Electrolytiques.) GUICHARD, CLAUSMANN, BILLON & LANTHONY. *Comptes Rendus*, Vol. 192, Mar. 9, 1931, pages 623–625.

The authors point out that the exceptional hardness of electrolytic iron has for a long time attracted attention. This hardness has been attributed, on the one hand, to the fine state of diffusion of the metal and, on the other, to the presence of a compound of hydrogen and iron having a characteristic metallographic structure. The authors have repeated the experiments of Hughes (*Revue de Metallurgie*, Vol. 22, 1925, page 764) and have arrived at a conclusion entirely different from that reached by him. The results of their experiments are briefly described and they conclude that it is necessary to exercise considerable caution before attributing the remarkable mechanical properties of electrolytic metals to the presence of occluded gases. The article is illustrated by 1 diagram and 6 photomicrographs. OWE(1)

PROPERTIES OF NON-FERROUS ALLOYS (2)

The Platinum-Iridium Alloys. FRANZ KORN. *Metal Industry*, London, Vol. 38, Mar. 20, 1931, pages 309–310.

Platinum-iridium alloys have high strength, a faint blue color, and are resistant to tarnishing. The tensile strength varies from 30 tons/in.^{2} with 5% Ir to 97 tons/in.^{2} with 30% Ir. Alloys containing more than 12% Ir increase in tensile strength when annealed between 600° and 800° C. Annealing temperatures should never be above 950° C. especially for alloys with more than 15% Ir, some of which is lost by volatilization. Corrosion resistance to hot aqua regia and sulphuric acid increases with Ir additions. Pd does not harden Pt alloys as effectively as Ir. Au increases both hardness and brittleness of Pt but the brittleness is counteracted by Pd. The Pd content should be 2 or 3 times the Au content to obtain best results with Pt-Pd-Au alloys. PRK(2)

White Metals, Brasses, and Bronzes. Pts. VI & VII. E. PERRY. *Metal Industry*, New York., Vol. 28, Aug. 1930, pages 376–377; Oct. 1930, pages 464–465.

Pt. VI. In Cu-Zn alloys, the alloy is usually of a red color when 85% or more of Cu is present. In making red brasses, Cu is melted first and other metals are added in the same manner as followed in yellow brasses. Clean flux should be used. Gives composition of a few representative brasses. Cu and Sn alloys with more than 5% of Sn are known as bronze. Bronze is made in the same way as brass. Bronze mixtures should be deoxidized with P-Cu or P-Sn except in the case of Al and Si bronzes. Includes a table giving standard and special bronze mixtures, illustrating some of the better combinations for certain purposes. Pt. VII. White brass and bronze alloys are usually very hard and, many of them, extremely brittle. In melting, the volatile metal is melted first, or in the case of 2 or more volatile metals, they are melted together. White metals proper are made without Cu. They are used for patterns, letters, ornaments, dishes, type-metal toys, etc. Includes tables showing typical mixtures of white brasses and white metals. VSP(2)

Commercial Aluminum Alloys from the Users' Point of View. J. B. HOBLYN. *Metal Industry*, London, Vol. 35, Dec. 20, 1929, pages 589–590. See *Metals & Alloys*, Vol. 1, July 1930, page 627. (2)

Dimensional Stability of Heat Treated Aluminum Alloys. J. D. GROGAN & D. CLAYTON (National Physical Laboratory). *Institute of Metals, Advance Copy* No. 553, 1931, 28 pages.

It was found that the change in length of both cast and forged heat treated aluminum alloys over a period of years was inappreciable. Changes in length on machining these alloys, however, may occur. Samples of Y-alloy, Duralumin, and 25S 3 in. in diameter by 5 in. long were heat treated and machined into dumb-bell form. As the outer surface was removed appreciable shrinkage occurred in the fully aged alloys. The shrinkage was greatest in those quenched in cold water, less in those quenched in oil and almost negligible in those quenched in boiling water. The decrease in length in some cases amounted to almost 0.020 in. Tensile and hardness tests indicated that the alloys quenched in boiling water were as effectively hardened as those quenched in cold water. Dimensional changes on machining did not occur in annealed alloys. The corrosion resistance of the hot-water quenched alloys may be low, and the greater resistance of the cold-water quenched alloys may result from compressive stresses in layers near the surface, which heal intercrystalline corrosion cracks. Contains 1 reference. JLG(2)

New Silicon-Zinc-Copper Alloys. Part I. The Use of Silicon as a Deoxidizer and Alloying Agent.—Preparation of the Alloys.—Determination of Solid Solubility Limits.—Mechanical and Physical Properties. E. VADERS (Hirsch, Kupfer- und Messingwerke A.-G.). *Metal Industry*, New York, Vol. 29, Mar. 1931, pages 108–110.

Using electrolytic Cu, pure Zn, and Si with an Fe content of 1–2%, alloys up to 6% Si were melted in a high frequency induction furnace. The solubility of Si is shown by straight lines through the points Cu 95, Zn 0, Si 5; Cu 79, Zn 18, Si 2; Cu 71.1, Zn 27, Si 1.9 in a ternary diagram. The physical properties of 10 alloys are given, tensile strengths varying from 23.4 to 50.8 kg./mm.^{2}, elongation from 2.2 to 28.3% and Brinell hardness (100 kg. load) from 77 to 140. See *Metals & Alloys*, Vol. 1, Dec. 1930, page 898. PRK(2)

Beryllium-Copper Alloys. EDMUND R. THEWS. *Canadian Chemistry & Metallurgy*, Vol. 15, Feb. 1931, pages 51–53.

Properties of Be and its alloys are reviewed. Be-Cu alloys include those with Be used as deoxidizing agent and containing 0.01–0.03% and with Be as alloying agent containing 1–3% Be. Age-hardening of these alloys does not depend upon the quenching medium. The effects of age-hardening on the mechanical properties of various Be-Cu alloys are indicated. The elasticity of Be-bronze is exceedingly high and these bronzes exhibit very good bearing qualities. Castings are free from pores and surface defects. A bibliography of seven references is included. WHB(2)

Effect of Combinations of Strain and Heat Treatment on Properties of Some Age-Hardening Copper Alloys. W. C. ELLIS & EARLE E. SCHUMACHER (Bell Telephone Labs.). *American Institute of Mining & Metallurgical Engineers, Technical Publication* No. 395, 1931, 13 pages.

Cu-Ni-Si and Cu-Co-Si alloys were studied. By heat treating and cold drawing an alloy containing 4% Ni + Si a tensile strength of 140,000–150,000 lbs./in.^{2} with an elongation of 30–33% was obtained. With 1% Co + Si the tensile strength was 85,000 and the conductivity 50%. Reheating to low temperatures increased the conductivity and slightly decreased the strength. Contains 3 references. JLG(2)

Compression Diagrams and Temperature-Hardness Curves of Some Lead-Tin-Antimony Alloys. (Stauchdiagramme und Wärmehärtekurven einiger Legierungen auf Blei-Zinn-Antimon-Basis.) EDUARD HERTEL & ARTHUR DEMMER. *Metallwirtschaft*, Vol. 10, Feb. 13, 1931, pages 125–126.

Compression stress-strain diagrams were prepared for 12 Pb-Sn-So alloys, using samples 20 mm. diam. and 25 mm. high and applying the load at the rate of 0.1 mm. per sec. These results and Brinell hardness tests are shown in the tabulation. In 10 X-ray examinations, the existence of a tetragonal Sn rich, a trigonal Sb rich, and a cubic constituent was found and the absence of any definite Sn-Sb compounds was proved.

	Composition							Load, kg./mm.^{2} at Compression					Brinell Hardness at		Ratio

PROPERTIES OF FERROUS ALLOYS (3)

Production and Properties of Stainless Steels. (Die rostfreien Stähle ihre Eigenschaften und Herstellung.) E. HOUDREMONT. *Krupp'sche Monatshefte*, Vol. 11, Nov. 1930, pages 270–286; *Revue de Metallurgie*, Vol. 28, Jan. 1931, pages 40–59.

The article corresponds to the publication in *Stahl und Eisen*, Vol. 50, Oct. 30, 1930, pages 1517–1528, reviewed in *Metals & Alloys*, Vol. 2, Jan. 1931, pages 31–33, and abstracted in Mar. 1931, page 63. GN(3)

Stainless Steels. V. V. KENDALL. *Metals & Alloys*, Vol. 2, Jan. 1931, pages 31–33.

A critical abstract. Original article appeared in *Stahl und Eisen*, Vol. 50, Oct. 30, 1930, pages 1517–1528. See abstract in *Metals & Alloys*, Vol. 2, Mar. 1931, page 63. ESC(3)

Hardenable Titanium Alloys. (Vergütbare Titan-Legierungen.) W. KROLL. *Metallwirtschaft*, Vol. 9, Dec. 19, 1930, pages 1043–1045.

Pure titanium is prepared by reducing $TiCl_4$ in an evacuated steel bomb with Na at 500° C. It can be hammered and rolled. Rockwell hardness C 36, melting point 1850° C., silver color. Its affinity toward O_2 is between Si and Al and it can be used to deoxidize steel. Technical Ti is produced by the alumino-thermic process with addition of S and contains about 20% Al. Ferrotitanium containing 20% Ti, 5% Al is prepared from ilmenite by reduction with ferroaluminum, and cuprotitanium contains 15% Ti and much Al. Ferrotitanium containing C is also produced by reducing ilmenite in an electric furnace with coal. An Al alloy with 0.5% Ti, also Cu and Si, has good casting properties. Low carbon Ti steel was produced by melting Armco iron and ferrotitanium in a high frequency furnace. Ti has little effect except in high percentages and then forms coarse grained steel. Ti hardens Ni steel when drawn 12 hours at 500° C. With 2.16% Ti, 10% Ni, 0.05% C Brinell hardness is 490, with 4.4% Ti, 12.5% Ni Brinell 615. Quenched in water at 950° C. the hardness was 285 and 350, respectively. The addition of Ni to Ti steels produces a much finer grain size. Steel containing 3.11% Ti, 20% Cr, and 5% Ni was 300 Brinell when quenched from 950° and 525 Brinell when quenched and drawn at 500° C. These alloy steels can be easily rolled. They must be cast immediately after adding the Ti to prevent formation of nitrides. The hardening effect is explained by the precipitation theory. CEM(3)

A Study of the Physical Properties of Electrolytic Cobalt and Its Alloys with Iron. W. C. ELLIS (Thesis for Ph. D.). *Rensselaer Polytechnic Institute, Engineering and Science Series*, No. 16, June 1927, 57pages. Bibliography of 31 titles.

Seven alloys of electrolytic cobalt and electrolytic iron, as well as the 2 metals themselves, were studied, chiefly in regard to magnetic and electrical properties. The cobalt was 99.91%, with 0.07% Fe, 0.02% Cu. Specific resistance of cobalt of this purity is 6.24 microhm cm. at 20° C., temperature coefficient (0–100°) 0.00604. At 446° C. on heating, cobalt changes from close-packed hexagonal to face-centered cubic. On cooling, the reverse change occurs about 50° lower. Above 446°, cobalt can be readily worked, below it, it is rather brittle. Small amounts of iron give alloys that are face centered cubic and workable, hot or cold. The inversion point does not show up in thermo-electric measurements. Alloyed with electrolytic iron of 99.965% purity (chief impurities 0.015% Cu and 0.006% C) the alloys at both ends of the range were ductile cold, but between about 30 and 80 atomic % iron, they were not ductile cold, and had to be hot-swaged. The whole range of alloys forged hot. Up to $66^2/_3$ atomic % cobalt, the iron cobalt alloys are body centered cubic in form. At 80 and above atomic %, the structure is γ, face-centered cubic. No compound was indicated by X-ray analysis. Lattice parameters, resistivities, temperature coefficients, thermo electric force, magnetization and permeability curves are given for the various alloys studied. Work of previous investigators on less pure materials had indicated remarkable magnetic properties for an alloy corresponding to Fe_2Co which were not confirmed in this work and it is suggested that the presence of silicon may be required to secure the properties previously ascribed to that composition. The work of previous investigators on the Fe–Co system is summarized. HWG(3)

Magnetic Properties of Nickel Alloys. (Proprietes magnetiques des alliages de nickel.) MARCEL BALLAY. *Industrie Electrique*, Vol. 39, Nov. 1930, pages 511–519.

Electric properties of Fe-Ni, Ni-Cr, Fe-Ni-C, Fe-Ni-Co and monel metal taken largely from American sources are given. JDG(3)

The Correlation of Mechanical Tests for Cast Iron. J. G. PEARCE. *Transactions & Bulletin, American Foundrymen's Association*, Vol. 1, Dec. 1930, pages 673–720.

Conditions of melting, composition and rate of cooling have a profound influence on cast-iron structure, hence their mechanical properties. The influence of the former is pronounced and surpasses minor differences in composition and section. Pearlite or the ferrite structure may be produced in irons of the same composition by variations in the melting practice. The strength varies continuously with section for bars cast at different diameters. Such changes cannot be represented by a simple physical law. Variations of physical properties with composition and size of section are given in numerous graphs. CHL(3)

Materials at High Temperatures, General Properties, Limiting Creep Stress and Limit of Proportionality. R. G. BATSON (National Physical Laboratory, England). *First Communications of the New International Association for the Testing of Materials.* Group A, Zurich, 1930, pages 74–79.

General discussion of the problem. Hatfield's "time-yield" short-cut method is mentioned, but Batson believes that only long duration tests which give a minimum creep rate of 10^{-5} inches per hour are adequate. See also *Metals & Alloys*, Vol. 1, Nov. 1929, page 241. HWG(3)

The Structure and Mechanical Properties of Pearlite. (Sur la perlite, sa structure et ses proprietes mechaniques.) N. T. BELAIEW. *Revue de Metallurgie*, Vol. 27, Dec. 1930, pages 680–685. 15 references.

The actual distance between lamellae of cementite and ferrite in pearlite is constant for all grains of a given specimen and is governed by the rate of cooling. Brinell hardness is unaffected by the grain size but is in direct relation to intralamellar distances. So that the latter can be derived directly from Brinell hardness properly accounting for the influence of other alloys present. JDG(3)

The Properties of Silicon Cast Steel (Ueber die Eigenschaften von Siliziumstahl in Form von Stahlguss). F. BONSMANN. *Mitteilungen Forschungs-Institut Vereinigte Stahlwerke Aktiengesellschaft Dortmund*, Vol. 1, No. 6, 1929, pages 147–176, 21 references.

A comparative study of 6 cast steels containing 0.14–0.18% C, 0.7–1.2% Mn, 0.7–1.3% Si, 0.3% Cu and 0.13% Ti, and of a plain C steel containing 0.39% C, 0.8% Mn and 0.45% Si. The Si steels exhibited a high degree of plastic deformation. As compared with C steel of the same tensile strength, the Si steels show better elongation, reduction of area and notch toughness. Elongation and reduction of area of the Si steel are 60% higher than those of the plain C steel. The notch toughness is about 80% higher in the Si steel than in the plain C steel. The best tensile properties are obtained by heating the Si steels at temperatures between 900° and 1000° C. Si steels require an annealing at 100–150° C. higher than the C steel. Tensile properties of the Si steel depend on the temperature. By adding 0.3% Cu, the Si steel becomes more resistant to corrosion. See article bearing the same title by Schulz and Bonsmann, *Metals & Alloys*, Vol. 1, Aug. 1930, page 690. GTM(3)

CORROSION, EROSION, OXIDATION, PASSIVITY & PROTECTION OF METALS & ALLOYS (4)

Corrosion Resistance of Aluminum and Its Alloys. (Korrosionsfestigkeit des Aluminiums und seiner Legierungen.) M. BOSSHARD (Aluminium-Industrie A.-G., Switzerland). *First Communications of the New International Association for the Testing of Materials.* Group A, Zurich, 1930, pages 293–303, 15 references.

Corrosion studies of aluminum with various contents of Si and Fe, by determination of temperature rise (reaction rate) in HCl, and by loss of weight in $NaCl$-H_2O_2, are described, on material after different degrees of cold working and different annealing treatments. The results of the 2 methods are not always consistent. The influence of Cu, Zn, Mg, and Mn is discussed. Potential measurements in 1% NaCl quiet, in 2% NaCl aerated, and in 1.3 N HCl and 1 N KCl are tabulated, from the literature, for the more common metals. The data for 2% NaCl aerated are extended to a dozen commercial aluminum alloys. Corrosion resistance depends on formation of a protective oxide skin. Pitting is due to electrochemical attack on this coating. HWG(4)

Corrosion Observations on Copper Bearing Steels (Erkenntnisse über den Korrosionsvorgang aus der Korrosion gekupferten Stahls). C. CARIUS (Vereinigte Stahlwerke Dortmund). *Zeitschrift für Metallkunde*, Vol. 22, Oct. 1930, pages 337–341; Discussion, Nov. 1930, pages 392–393.

The author investigated the mechanism of corrosion on Cu-bearing steels and discovered Cu deposited at the surface. In distilled water the metal deposited stuck tightly to the steel while rusting in salt solutions yielded spongy Cu-films which flaked off. The nature of the deposited metal decisively affected the developing process of rusting. By means of solutions containing Fe^{II} and Fe^{III} salts, Carius explains the reactions encountered in such oxidation-reduction-chain. By comparing the oxidation potential of an aqueous corroding medium with the magnitude of the potential of a metal against the corrosive medium, the corrosion stability of the metal in this solution can be anticipated. By a comparison of the oxidation potential of an aqueous medium with the position of the potential of a metal toward that reagent, the resistance of the metal may be forecast. Paper at the Corrosion Meeting of the Deutsche Gesellschaft für Metallkunde. EF(4)

Results of Water Treatment. T. F. POWERS. *Railway Age*, Vol. 90, Feb. 7, 1931, pages 329–331.

From a paper "Feedwater and Its Relation to Boiler Troubles" before the Western Railway Club, Chicago, Dec. 1930. Water treatment on the Chicago & North Western has cut down the failures due to leaky flues from one for each 58,633 miles in 1911 to one for each 4,343,302 miles in 1929. Wayside treating plants under proper supervision is the most satisfactory method. Since 1911 trouble has been encountered with the embrittlement of boiler plates in the shells of locomotive boilers. The characteristics associated with this trouble are: it is confined to certain definite districts; it is more prevalent in locomotives in passenger service; the cracking is generally discovered below the water line; in horizontal seams it is always confined to the outside row of rivets; it appears always to start from the dry side of the plate; before failure occurs, the cracks are generally discovered by small hairline cracks which readily open up under heat; there is no elongation of the plates and, in many cases rivet heads break off before failure occurs; the cracks are very irregular but usually follow a general direction; the cracks seem to be more numerous and appear to start where the plates are not well laid up; in many of the cracked plates the chemical analysis shows that the steel manufacturers are complying with the specifications, although at the point of fracture decided crystallization is observed; the steel is very brittle and, in many cases, looks like cast iron. The theory that the cause of this cracking was due to poor material or poor workmanship was finally discarded. Localized strains combined with excessive use of sodium hydrate as determined by the work on this subject at the University of Illinois was considered the cause. Since it was impossible to relieve the strains, the feed water treatment was revised with a material decrease of the trouble. VVK(4)

Materials, Physical Properties and Corrosion. (Werkstoffe, physikalische Eigenschaften und Korrosion.) E. RABALD. Vol I. General and Metallic Materials. 976 pages. Vol. II. Non-Metallic Materials. 392 pages. O. Spamer, Leipzig, 1931. Paper, 7 × $9^3/_4$ inches. Price for both volumes 135 RM.

This huge compendium of the corrosion resisting properties of metallic and non-metallic materials is a "monumental work." It represents the labor of 5 years, and contains 10,000 references. The section on corrosion of iron and steel alone contains 2781 references, each one to an article that has been referred to in the text.

The volumes are chiefly a classified bibliography on corrosion, in which earlier texts have been freely used, but there is also considerable information on the physical properties of metals and alloys. The German standard specifications are given in many instances.

The books are written primarily from the point of view of the chemist. The effect of every chemical compound on whose corrosive action data are available, is entered under the various metals and alloys. Thus, one finds, for example, that 5% Maleic acid dissolves 0.093 g./dm.^{2} from Corronil in 500 hours, and that trichlorethylene dissolves 0.2 g./dm.^{2} from iron in 7200 hours. The books are rich in that sort of data, and while the test conditions can seldom be stated in detail, references to the original articles are given. Some 30 pages are devoted to the principles of corrosion, some 20 to methods of corrosion testing, and less than 20 to prevention of corrosion.

There is little attempt to deal critically with data found in the literature or to correlate laboratory tests and service results. Zinc coatings are discussed, but no mention is made of cadmium coatings.

Corrosion fatigue is barely mentioned, and its engineering importance is not brought out. The only inkling that weight losses may not tell the whole story in the corrosion of duralumin is contained in the comment that while the Mylius test is often used, Rackwitz and Schmidt measure the progress of corrosion by means of physical properties. In Fig. 128, tensile strength and elongation are plotted to show a drop in both with time of corrosion, but the ordinates are not given, and the text does not make clear whether the curve relates to duralumin or to aluminum alloys in general, nor what the conditions of corrosion were. Nothing is said about intercrystalline attack of duralumin. The engineering point of view is almost absent, and attention is focused on chemical attack.

The volume on non-metallic materials deals with glass, wood, cement, rubber, leather, tar, paints, varnishes, etc., etc.

The books are highly valuable as bibliographies, and their scope is larger than that of corrosion alone. For the metallurgist seeking an understanding of the mechanism of corrosion and the utility or otherwise of laboratory methods for accelerated corrosion testing, or for the engineer wishing to get an idea of what actual service he may expect of metals and alloys as structural materials under corrosive conditions, they cannot compare with the publications of Evans or Speller. But as a source of references to the general literature of corrosion, they are the latest and most complete.—H. W. Gillett (4)-B-

Recently Discovered Facts about Corrosion. F. N. SPELLER. *Metal Progress*, Vol. 1, Sept. 1930, pages 48–53.

A review of the methods of combating corrosion of ferrous materials. Protection by alloying, by coating with more resistant metals, and by painting is discussed. For brine circulation systems and other special cases the use of chemical agents to produce a "passive" film is often advantageous. Corrosion under stress, corrosion in steam plants, and soil corrosion are taken up. WHK(4)

Protection of Building Materials against Chemical and Physical Attack. (Schutz der Bauwerke gegen chemische und physikalische Angriffe.) O. GRAF & H. GOEBEL. Wilhelm Ernst & Sohn, Berlin, 1930. Paper, 7 × 10 inches, 224 pages. Price 22 RM.

The bulk of this book deals with concrete construction, with some attention to wood. About 40 pages deal with metals, some 25 being devoted to corrosion (written by H. Wolf), 3 pages by Graf dealing with high temperature properties of steel, wrought iron and cast iron in sketchy fashion, and the balance on protection of iron bridges against corrosion by K. Schaechterle.

Points of design so that water will drain off are brought out. The principles of corrosion are briefly discussed, and protective paints are very briefly dealt with. Various metallic coatings are mentioned. While the book will be of interest in regard to concrete, there is not much in it that will be new or very informative to the metallurgist.—H. W. Gillett (4)-B-

New Materials of Construction Reduce Corrosion Losses. JAMES A. LEE. *Chemical & Metallurgical Engineering*, Vol. 38, Mar. 1931, pages 153–154.

Paper before Technical Association of the Pulp and Paper Industry, Feb. 20, 1931. The 18% Cr, 8% Ni ferrous alloy when properly installed is valuable for resisting corrosion in sulphite mills. Modification of the composition of this alloy gives better corrosion resistance to sulphite as the following table indicates:

Corrosion Resistance of a "20–10" Cr-Ni Alloy 1% Sodium Bisulphite—3% Sulphurous Acid Temperature 300° F. Pressure 50–55 lbs./in.²

C	Cr	Ni	Mo	Loss/in.²/hr.
0.13	17.39	8.39	—	0.511 milligrams
0.12	20.39	10.76	—	0.182 milligrams
0.13	17.74	8.30	2.0	0.347 milligrams

Carbon is also used to resist sulphite corrosion, for instance in making tight joints in steam connections to paper machine drying cylinders, in replacing wooden suction boxes, and in digestor linings. Molded plastics are being used as scraping blades, impellors, gears, etc. PRK(4)

Protective Coatings, Rust Protection and Coloring of Aluminum. (Ueberzüge, Rostschutz und Färbung des Aluminiums.) HERBERT KURREIN. *Metallwirtschaft*, Vol. 9, Dec. 19, 1930, pages 1049–1050.

Al can be Cd plated in a solution of 11 g. $CdCO_3$, 35 g. $Cd(CN)_2$, 5 g. Na_3PO_4, 7.5 g. $K_4Fe(CN)_6$ and 2.5 g. gelatine/l. at 0.5–0.7 amps./sq. dm. and 3.5 volts. Cd gives protection against salt water. Cr cannot be plated directly on Al. Cr over Cd gives very good protection. Plated coatings on Al should be tested by determining the thickness by stripping, by bend tests and corrosion tests. The advantages of high strength Al alloys and corrosion resistant pure Al are combined in Allautal, Duralplat and Alclad, which consist of Al alloys with a layer of pure Al on each side, held mechanically by rolling together. The protecting layers are about 10% of the total thickness. Some protection is obtained by dipping Al in 10% NaOH, then 5 min. in conc. HNO_3 at 60° C. and anodic treatment in very pure chromic acid. By dipping in an almost boiling bath of 10 g. CaO and 10 g. $CaSO_4$/l. of H_2O a white or gray coat of $Al_2(SO_4)_3$ is formed. Al cannot be colored itself, except after plating with Cu, Ni or Fe. Black lines are formed by dipping in 10 g. $NiSO_4$, 5 g. Na_2SiF_6, 25 KNO_3 and 4 l. H_2O. CEM(4)

Acidity and Corrosion in Canned Fruits. E. F. KOHMAN & N. H. SANBORN (Research Laboratory, National Canners Association). *Industrial & Engineering Chemistry*, Vol. 22, June 1930, pages 615–617.

Data are presented to illustrate the effect of pH on the single and relative potentials of Fe (base plate) and Sn. It is probable that the effect of pH is more or less influenced by the acid radical of the acid used. Nevertheless, there is a tendency for the Sn to become less and less noble compared with Fe, as the pH becomes lower. This explains the perforation tendency of the less acid fruits in enameled cans. MEH(4)

Resistance of Stainless Steels to Dilute Sulphuric Acid (Ueber das Verhalten der nichtrostenden Stahle gegen verdünnte Schwefelsäure). J. FRITZ. *Krupp'sche Monatshefte*, Vol. 11, Nov. 1930, pages 267–269.

The article points out that the conclusions of some authors, who investigated the attack of dilute sulphuric acid on stainless steels as to the instability, do not correspond to the facts. GN(4)

The Influence of Contact with Other Metals on the Corrosion of Aluminum and Its Alloys. G. AKIMOW (Central Aero-Hydrodynamical Institute, Moscow). *First Communications of the New International Association for Testing Materials*, 1930, Group D, pages 127–140.

Study of the electrode potentials of Al, duralumin, etc., in 3% NaCl, or 3% NaCl + H_2O_2, indicates to Akimow that pure Al, Zn, or Cd will give electrochemical protection to duralumin while Zn will protect pure Al. It is claimed that Zn will even protect duralumin in contact with Cu or with stainless (Cr) steel. The test methods are briefly described and results shown in curves. HWG(4)

Investigation of the Action of Disinfectants and Cleaning Materials on Metals. (Untersuchungen über das Verhalten der Metalle gegen Desinfektions—und Reinigungsmittel.) W. GUERTLER, T. LIEPUS, MOHR & OSTERBURG. *Metallwirtschaft*, Vol. 9, May 23, 1930, pages 447–449.

Sheet samples of 40 different metals were immersed for 24–48 hours at 45–50° C. in 24 disinfectants and cleaning solutions, included in the following 7 groups: Organic Cl preparations, organic Cl preparations with alkalies, inorganic Cl preparations, alkali mixtures, formaldehyde and similar mixtures, cresol-soap preparations and sodium phosphate mixtures. The samples were carefully cleaned, loss in weight was determined and they were examined microscopically. Iron and steel was attacked by most of the solutions, copper was not much better. Tinned steel and tinned Cu are fairly satisfactory, also tinned Cu which had been soldered. Zinc is very poor. Ni, Ni alloys, KA-2 steel and chrome plated steel were best, KA-2 steel being attacked by only 2 solutions. Al and Al alloys are attacked by all acid and alkaline solutions. Alkaline solutions containing sufficient sodium aluminate can be used for Al. CEM(4)

Selections of Rust Preventives. BERNARD JEFFS. *Black & White* (E. F. Houghton & Co.), Vol. 3, Feb. 1931, pages 17–19.

Discussion of "at least 9 fundamental properties" which must be possessed by rust preventives. MFB(4)

The Effect of Artificial Ageing upon the Resistance of Super-Duralumin to Corrosion by Sea-Water. K. L. MEISSNER (Dürener Metallwerke A. G.) *Institute of Metals, Advance Copy* No. 557, 1931, 15 pages.

Specimens of super-Duralumin (0.8 Si) that had been quenched from 500° C., and aged for 20 or 40 hrs. at temperatures up to 200° C. were exposed in the North Sea for 3 months. During exposure they were under water for 7 or 8 hrs. and in the air for 4-to-5 hr. periods. The corrosion was determined by appearance, change in weight, change in tensile properties and microscopic examination. The samples aged at 125° and 145° C. were badly pock-marked. Tensile tests indicated that these samples had been most severely attacked. Microscopic examination showed that these samples were corroding at the grain boundaries and that the pock-marks were caused by chunks of Al falling off. In such an alloy there is therefore a critical tempering range between 100° and 150° C. at which the corrosion resistance is at a minimum. This range is just below the critical hardening temperature. 6 references. JLG(4)

Corrosion-Resistant Metals and Alloys in the Dairy Equipment. C. L. MANTELL. *Food Industries*, Vol. 1, Oct. 1929, pages 585–587.

Review of the latest research work relating to materials of construction for food equipment, particularly for milk and milk products. Considers the use of Monel Metal, Ni and Ni-Cr steels. See *Metals & Alloys*, Vol. 1, Feb. 1930. page 385. (4)

STRUCTURE OF METALS & ALLOYS (5)

Metallography & Macrography (5a)

Some Structural Characteristics of High Chromium Irons and Steels. J. H. G. MONYPENNY (Brown Bayley's Steel Works). *Metallurgia*, Vol. 1, Dec. 1929, pages 61–64; Jan. 1930, pages 115–118.

As the Cr in steel is increased the austenitic field contracts. The 12% Cr steels are susceptible to heat treatment, but, particularly in the low carbon alloys, as the Cr is increased the susceptibility to heat treatment decreases. This is due to the formation of ferrite, and if the Cr is high enough and the C low there is no phase change at any temperature in the solid alloys, and the only method of grain refinement is by working. In the high Cr steels carbides may fail to dissolve on heat treatment, and thereby decrease the quantity of Cr effective in preventing corrosion. The thermal treatment necessary to produce the desired physical and chemical properties depends on both the C and Cr concentrations. 4 references. JLG(5a)

The Metallurgical Microscope. *Metallurgist*, Feb. 1931, pages 17–18.

Begun as little more than a hobby, which gradually achieved recognition as a method of research, the microscopic examination of metals has become a recognized feature of our laboratories, both industrial and purely scientific. Although the development of other methods of investigation such as X-ray spectrometry has suggested the replacement of the microscope, yet for much investigatory work of a practical nature and for routine purposes, the microscope has come to stay. The present-day tendency is to replace visual observation with the microscope entirely by photographs. Thus microscopes are constructed for that purpose and no provision made for convenient visual observation. The eye can travel over the entire specimen and get a much better idea of the average structure than the small area represented in a photograph unless that area is chosen with painstaking skill and judgment. Insufficient observation and too hurried a recourse to photography may lead to erroneous results, the misinterpretation of the indications of structures, and may serve to discredit the value of metallurgical microscopy, more especially for practical purposes. Diffusion of Iron and Tungsten in the Solid State. (Die Diffusion von Eisen und Wolfram in festem Zustand.) K. SCHNEIDER. *Doktor-Ingenieur dissertation Tech. Hochschule*, Stuttgart, May 25, 1927, 55 pages, 9 figures, 29 micrographs, 47 references. Published by R. Noske, Borna-Leipzig.

Electrolytic Fe was heated in W powder in a H_2 atmosphere for various lengths of time ($7^1/_2$ to 72 hrs.) at 1280°, 1330° and 1400° C., layers turned off the Fe and analysis of each layer made for W. For example, heating at 1330° for 48 hours gave a surface with 10% W at the surface, the W content decreasing in a smooth curve to 3.6% at about 0.035" and from that depth it fell along another smooth curve to around 0.1% at about 0.05". The diffusion coefficients were calculated to be, in 10^{-5} cm.²/day, at 1280°, 1.9; at 1330°, 4.3; at 1400°, 1.5. Corrosion tests were made of 11 Fe-W alloys with $6^1/_2$ to 75% W, in $^1/_{10}$ N HNO_3 and 1 N H_2SO_4 and HCl. Minimum attack under the test conditions was at 41% W in HNO_3 and at 5 to 35% W in the other two acids. Tammann's "rule" of eighths was not verified. Hardness tests showed a straight-line rise from zero to $63^2/_3$% W the maximum being 129 Rockwell B, then a fall to 113 Rockwell B for W itself. From microscopic examination, hardness and corrosion tests the compound Fe_2W was indicated to exist.—H. W. Gillett (5a)-B-

The Polishing of Surfaces. J. M. MACAULAY. *Journal Royal Technical College*, Glasgow, Vol. 2, Jan. 1931, pages 378–385.

While this article deals with the polishing of glass, it is of interest in regard to metallographic polishing. The hypothesis that a polishing process may involve high local temperature, sufficient to soften the surface, and enable it to flow, was examined by polishing glass under water with a pressure of 1 lb./in.² with Pb_3O_4 for 1 hour, after which it was thought that the red lead was more yellow in color, indicating presence of PbO, which is formed on heating Pb_3O_4 to 450° C. On polishing flint glass under water for 17 hours with $CaCO_3$, the water showed traces of CaO, indicating that a temperature of around 900° C., necessary to convert the $CaCO_3$ used into CaO, must have been reached. From these experiments it is concluded that local high temperatures may exist during polishing. HWG(5a)

The Relation between the Hydrogen Overvoltage and Composition of Brass. M. DEKAY THOMPSON. *Preprint* 59–7, *American Electrochemical Society*, April 1931 meeting, 4 pages.

The hydrogen overvoltages on brass are measured for compositions varying from pure Cu to pure Zn. The points on the overvoltage-composition plot would lie nearly evenly distributed about a straight line drawn between the values for pure Cu and pure Zn, except for a decided minimum in ϵ-brass. Maxima have been found in other alloys, but this is the first sharp minimum. There is no close connection of the overvoltage with the equilibrium diagram. (5a)

The Solid Solutions of the Copper–Silver System. D. STOCKDALE (King's College, Cambridge). *Institute of Metals, Advance Copy* No. 559, 1931, 14 pages.

The solid solubility of Ag in Cu and Cu in Ag were determined by microscopic and electrical methods. The solubility of Ag in Cu is 8.2% at the eutectic temperature, 4.7% at 700° C., 0.7% at 400° C., and probably almost zero at room temperature. The solid solubility of Cu in Ag is 8.8% at the eutectic temperature, 5.8% at 700° C., 1.1% at 400° C., and about 1% at room temperature. The Cu rich solidus curves downward sharply near the limit of solid solubility. The Ag rich solidus is nearly a straight line. JLG(5a)

Explanation of the Complex Phenomena Observed during the Drawing of "Hyper-Hardened" Steels (Explication des phénoménes complexes observés pendant le revenu des aciers hypertrempés). ALBERT PORTEVIN & PIERRE CHEVENARD. *Comptes Rendus*, Vol. 191, Oct. 13, 1930, page 608–610.

In previous papers (*Comptes Rendus*, Vol. 188, 1929, page 1670; Vol. 191, 1930, pages 252 and 408) the authors have described the mechanism of the drawing of "hyper-hardened" steels (steels consisting of retained austenite) and have classified the phenomena under 3 heads:

	Reaction	Observed	Volume Change
I.	Supersaturated γ-solution → cementite → less carburized γ-solution.	During heating	Contraction
II.	γ-solution → cementite + less carburized α-solution	During heating	Expansion
III.	γ-solution → α-solution	During cooling	Big expansion: A"

In this paper, the authors discuss the first 2 reactions. During the isothermal drawing of austenite, when studied by the usual dilatometric method, an expansion or contraction is usually observed and it should be possible to connect the change in length exclusively with one or other of the reactions I and II. Further, any change in the direction of the dilatometric manifestation should show the order in which the reactions, even when they occur simultaneously, has now been confirmed by the authors who describe an improvement in technique which has enabled this to be accomplished. The results of experiments on a 1.5% C, 2.0% Cr steel are briefly described in this connection. OWE(5a)

Heat Treatment and Metallography of the Alloys of Iron and Manganese. V. N. KRIVOBOK & CYRIL WELLS. *Mining & Metallurgical Investigations, U. S. Bureau of Mines & Carnegie Institute of Technology, Mining & Metallurgical Advisory Boards*, 4th Open Meeting, Oct. 17, 1930, 4 pages.

Dividing the Fe-Mn alloys into 6 groups the micro-structure of each group is discussed individually but briefly. (5a)

Structure & X-Ray Analysis (5b)

A Practical Accessory in X-Raying Materials (Ein Praktisches Hilfsmittel bei der Durchleuchtung von Werkstücken mit Röntgenstrahlen). F. STÄBLEIN. *Krupp'sche Monatshefte*, Vol. 11, Dec. 1930, pages 316–317.

In X-raying large pieces of material, difficulties are generally encountered in covering those parts which should not be X-rayed. Since all previously suggested methods were found to be wasteful of time, the Krupp laboratories have developed, for this purpose, a mixture of plasticine with tungsten powder. GN(5b)

Preparation and Study of Bismuth Crystals. L. SCHUBNIKOW & W. J. DE HAAS. *Journal Russian Physical Society*, Vol. 62, pages 529–537 (in Russian).

Apparatus is described for production of crystals of any predetermined shape and any desired orientation of crystalline axes. The latter is achieved by placing in the apparatus a properly oriented crystalline nucleus before filling it with molten metal. Crystals form better when the main axis of the crystalline nucleus is perpendicular to the long dimension of them. When it has a parallel position the crystallization is handicapped and a strong tendency toward formation of twins can be observed. No secondary crystals were found either by a microscope or by using X-rays where no rings were observed, only spots. No coating with polycrystalline layer was found. Electric conductivity studies showed that no intercrystalline fractures were formed up to the load of 300 g./mm.^{2} (5b)

X-Rays and Metallurgy. L. PICKUP. *Metallurgia*, Vol. 3, Jan. 1931, pages 101–103, 108.

Mention is made of radiography and methods for studying crystal structure are described. Lists the crystal structures of the common metals. JLG(5b)

Twinning in Metals. C. H. MATHEWSON (Yale University). *Transactions, American Institute of Mining and Metallurgical Engineers*, Vol. 76, 1928, pages 554–601; *Proceedings Institute of Metals Division*, 1928, pages 7–54.

Lecture at New York meeting, Feb. 1928. A comprehensive discussion of twinning in metals. Twinning is common in face-centered cubic and hexagonal metals. There is some question whether or not twinning occurs in body-centered cubic metals, but Neumanns in α-iron are probably twins. Twinning is common in some of the metals of lower symmetry. Experimental work that illustrated the mechanism of twinning in zinc is reported in detail. Twinning in brass and iron is described in less detail. 50 references. JLG(5b)

Lattice Distortions as a Factor in the Hardening of Metals. H. W. GILLETT. *Metals & Alloys*, Vol. 1, Oct. 1930, page 781.

A critical abstract of a paper by the same name by W. L. Fink & K. R. Van Horn before the Institute of Metals, Oct. 1930. See *Metals & Alloys*, Vol. 1, Nov. 1930, page 845. ESC(5b)

New Applications for the X-Ray Are Continuously Being Discovered. DON. S. BROWN. *Electric Journal*, Vol. 28, Feb. 1931, pages 88–90.

A review indicating the applications of the X-ray to the medical, therapeutic industrial fields, arts and sciences, X-rays have been used to detect flaws and blow holes in castings, to inspect welds and insulated electric conductors; to check the workmanship of complex mechanical assemblies such as shells; to detect impurities in sugar and flour to determine the amount of ash in coal and the proportion of fat to lean in canned beef, etc. WHB(5b)

The Crystal Structure of the Compound Fe_2B (Kristallbau der Verbindung Fe_2B). GUNNAR HÄGG. *Zeitschrift für Physikalishe Chemie*, Part 2, Vol. 11, Dec. 1930, pages 152–162.

Fe_2B crystallizes on a tetragonal body-centered lattice with 4 molecules within the unit cell. The coordinates of the positions of the iron atoms are as follows:

$$m, m, p; \quad m + 1/2, \underline{m + 1/2}, p + 1/2 \qquad m, \overline{m}, p; \quad m + 1/2, \underline{1/2 - m}, p + 1/2$$

$$\underline{m, m, p}; \quad 1/2 - m, 1/2 - m, p + 1/2; \qquad \underline{m, m, p}; \quad 1/2 - m, m + 1/2, 1/2 - p.$$

The parameters are $m = 1/6$ and $p = 1/4$. The boron atoms occupy points having the following coordinates:

$$1/2\ 0\ 0;\ 1/2\ 0\ 1/2;\ 0\ 1/2\ 0;\ 0\ 1/2\ 1/2$$ OWE(5b)

Crystal Structure of the Alloys of Iron and Manganese. JAMES B. FRIAUF & MAXELL GENSAMER. *Mining & Metallurgical Investigations U. S. Bureau of Mines & Carnegie Institute of Technology, Mining & Metallurgical Advisory Boards, 4th Open Meeting*, Oct. 17, 1930, 6 pages.

On X-ray analyses α-Fe is present in Fe-Mn alloys up to at least 16% Mn. γ-Fe makes its appearance at room temperature in the forged alloys with 13% Mn. Another phase, the hexagonal close packed arrangement, was found in forged alloys containing 10–26% Mn. (5b)

Solubility of Carbide in Ferrite. H. A. DICKIE. *Fuels & Furnaces*, Vol. 8, May 1930, pages 653–654, 682.

From a paper read before the Iron & Steel Institute. See *Metals & Alloys*, Vol. 1, Jan. 1930, page 340. MS(5b)

X-ray Studies of the Aging Problem. I. (Röntgenographische Studien zum Vergütungsproblem. I.) E. SCHMID & G. WASSERMANN. *Mitteilungen der deutsche Materialprüfungsanstalten*, Sonderheft 13, 1930, pages 41–46; *Metallwirtschaft*, Vol. 9, 1930, page 421.

This deals with duralumin (German specification 681 B) aged at room temperature, with and without cold working immediately after quenching. On aging, the lattice constant first shows a very small contraction, taking place through the "induction period" of the increase in hardness, but thereafter shows practically no change. Lattice distortion was not observed during room temperature aging; there was no widening or increase in fuzziness of the Kα doublet. However, widening and fuzziness of the lines occurs upon deformation of the hardenable Al alloys, and it is conjectured that this phenomenon is connected with the presence of a supersaturated solid solution. HWG(5b)

Investigation of the Make-Up of Metallic Systems by X-Rays. (Untersuchung über den Aufbau metallischer Systeme mittels Röntgenstrahlen.) A. WESTGREN (University of Stockholm). *Zeitschrift für Metallkunde*, Vol. 22, Nov. 1930, pages 368–373. 12 references.

X-ray examination can no longer be dispensed with in modern metallurgical research laboratories according to Westgren who aims at an early adoption of this testing method in scientific metallurgy. By a set of clear, typical photograms (powder-method) of Ag-Cd alloys, α-bronze, carbide phases of various steels and γ-brass phases, the author demonstrates the potentialities of X-ray photography. The border lines of ranges of homogeneity in constitutional diagrams can safely be established by means of space lattice measurements, and the various phases of a system can reliably be identified by the X-ray method. The classification of intermetallic phases based on their crystal structure yielded a relationship between the formation of certain types of atomic arrangements in alloys and their properties or the concentration of quanti-valence electrons. The same laws regarding the formation of the β- and γ-phases in Cu, Ag and Au alloys seem to hold true as well for the alloys of the transition elements. EF(5b)

PHYSICAL, MECHANICAL & MAGNETIC TESTING (6)

Wire Ropes and Wires for Rope. (Drahtseile und Seildrähte.) A. PAULI (Swiss Railways). *First Communications of the New International Association for Testing Materials*, 1930, Group D, pages 141–148, 9 references.

Discusses the incompleteness of present knowledge and of testing methods in this field. HWG(6)

Fatique Strength of Welded Steel Joints (Dauerfestigkeit geschweisster Stahlverbindungen). W. HOFFMANN. *Zeitschrift Verein deutscher Ingenieure*, Vol. 74, Nov. 15, 1930, pages 1561–1564; *Autogene Metallbearbeitung*, Vol. 24, Apr. 1, 1931, pages 99–102.

Oxy-acetylene welded steel pipes of different compositions and the electrically welded German steels, St 37, St 48 and St 52, are examined with regard to their physical and dynamic strength. From the test results which are produced in detail with microphotographs, it can be concluded that the welded pipe joints had an average strength of 50% of the material. Care must be taken that the local heat development during welding does not become too high and that it has a uniform distribution throughout the whole piece. The seam must not be too wide but, especially, not too high since this influences the permanent strength. Easy weldability (fusibility) of the material of the piece and of the added material is essential. The permanent strength of electric arc welds depends greatly upon the electrode material (added material). The latter should give absolutely forgeable welds. The burning depths should be as great as possible and have the proper proportion to the piece and its heating. The seam should show a smooth surface. Impact fatigue strength and vibration strength are very likely to be higher than in riveted joints. 7 references. Ha(6)

Structure Changes in Duralumin during Tensile Testing. E. F. BACHMETEW. *Transactions of the Central Aero-Hydrodynamical Institute*, No. 71 (in Russian), 36 pages.

Changes taking place during the deformation of duralumin in a tensile machine were studied. Duralumin sheets 2.5 mm. thick in annealed, quenched and aged, and quenched state were used as specimens. Polished and etched specimens were loaded in an Amsler machine for about one minute with a given load, permanent deformation determined and the structure photographed. The cycles were repeated on the same specimens but with increasing loads until the failure occurred. The type of heat treatment has no effect on the character of crystalline changes. With low stresses a certain amount of deformation of individual crystalline units was observed with some shifting of relative positions and rotation but without any appreciable modifications within the body of units. With the increasing loads a certain darkening of some areas of the surface caused by its bulging was observed which was followed on further loading by the appearance of slippage lines. They originated within the grains growing gradually to the periphery, always being parallel to each other in any given grain. At the latest stages of deformation a second set of slippage lines appeared being almost symmetrical with the direction of deformation and crossing the former pattern. No twinning was observed. (6)

Fatigue and Impact Testing of Welded Products. T. M. JASPER (A. O. Smith Corporation). *Preprint, American Society for Testing Materials*, Mar. 1931, 7 pages.

Fatigue testing is useful for selection of types of steel for engineering use, and in study of welding methods, but it is a slow research method, not suitable for routine testing. Impact testing may not closely represent the service conditions, but will differentiate a brittle weld from a tough one. The most practical test for welded pressure vessels in a severe hydraulic pressure test. HWG(6)

Testing Mine Cables. (Die Prüfung der Hebeseile für Bergwerke.) A. N. DINNIK (Russian Berginstitut). *First Communications of the New International Association for Testing Materials*, 1930, Group D, pages 149–155, 1 figure.

In Russia the strength of a cable is calculated from the strength of the wires that make it up. This is not adequate; the cable itself should be tested. HWG(6)

Fatigue Tests on Iron and Steel. (Utmattningsprov pa Järn och Stal.) AXEL LUNDGREN. *Jernkontorets Annaler*, Vol. 115, Jan. 15, 1931, pages 1–70.

Besides a detailed review of the most important results obtained in different countries by studies on the fatigue of metals, a report is given on investigations carried out at the Government Testing Institute, Stockholm. The results of these investigations, which were made with the "Alpha" testing machine may be summarized as follows. Test bars for one-sided load were made with 0, 1, 2, 5 and 10 mm. fillet radii. A radius of 10 mm. gave 90% higher fatigue limit than a radius of 0 mm. and 2% higher than a radius of 5 mm. Tests with constant moment gave a 2–3% higher fatigue limit than tests with one-sided load. The number of steels were investigated with the object of studying the relation between endurance and heat treatment as well as between endurance and other mechanical properties. Widely differing annealing temperatures were found to have a very slight influence on the fatigue limit. On the other hand, the endurance is considerably increased by quenching and varies with the degree of tempering. No marked relation was found between the fatigue limit and the limit of proportionality or the yield point. The relation between endurance and ultimate stress is more pronounced. A scrutiny of the results of this and previous investigations indciated, that the ratio K of fatigue limit to ultimate stress varies within certain limits and increases with reduction of area. By plotting K against reduction, diagrams were obtained for steels with different micro-structure, from which the following conclusions may be drawn. *Pearlitic carbon steels.* K = 0.37 for a reduction of area less than 36%. Above this value K increases with reduction. *Pearlitic Ni and Cr steels.* Higher values of K than in pearlitic carbon steels. *Sorbitic steels.* Considerably higher values of K than in pearlitic steels. Increase of K with reduction of area not so pronounced as in pearlitic steels. *Steels containing a mixture of sorbite, pearlite and ferrite, with the ferrite in the form of network.* K considerably lower than in sorbitic steels, sometimes even lower than in sorbitic steels, sometimes even lower than in pearlitic. *Martensitic-troostitic steels with high ultimate stress.* Lower values of K than in sorbitic steels. A one page English summary is given. 43 references. HCD(6)

The Effect of Surface Condition on Fatigue Tests Results. C. H. M. JENKINS (National Physical Laboratory, England). *First Communications of the New International Association for the Testing of Materials*, Group A, Zurich, 1930, pages 145–148, 15 references.

Discrepancies between laboratory fatigue tests and service performance under repeated stress may be due to differences in actual stress from presence of sharp corners, notches, scratches, etc., to differences in the surface, due to decarburization, surface cracks from machining or quenching, or to internal stresses, when these factors are removed in the preparation of the laboratory specimen, or else due to corrosion or other alteration of the surface in practice. HWG(6)

Comparison of Results of Tests in Tension, Torsion and Bending. G. COOK (King's College, London). *First Communications of the New International Association for Testing Materials*, 1930, Group D, pages 26–30, 10 references.

The elastic limit is not reached at the same stress in tension, torsion and bending, which is not explained by present theories. A metastable state at the elastic limit is suggested for mild steel. HWG(6)

ELECTRO-CHEMISTRY (7)

Electroplating (7a)

Some Properties of Protective Films on Metals. ERNEST S. HEDGES. *Chemistry & Industry*, Vol. 50, Jan. 9, 1931, pages 21–25.

A review of film properties with special consideration of the work carried out by Evans and the author. A theory of anodic polarization is offered, according to which OH ions are discharged simultaneously with other anions, such as SO_4 ions for instance, if a certain critical current density is reached and more SO_4 ions are discharged than can be replaced. This has the effect of producing a layer of oxide or basic salt on the surface. The presence of SO_4 ions renders this film non-protective, but it has the effect of raising very greatly the effective current density at those areas of the electrode which are uncovered. The consequence will be that in some spots the discharge will consist of OH ions only, which give a perfectly continuous oxide film. The discontinuous film first formed will be thrown off the electrode by the subsequent evolution of O_2. (7a)

The Effects of Acids and Alkalies on the pH of Nickel Baths. W. LOCKERBIE. *Brass World*, Vol. 26, July 1930, page 175.

The Deposition of Nickel at a Low pH. H. C. MOUGEY & W. M. PHILLIPS (General Motors Corporation). *Brass World*, Vol. 26, July 1930, pages 159–61.

The authors experimented with a Watts' nickel solution at pH's from 60 down to 1 at varying temperatures and current densities. There appears to be two ranges of pH, from 5.5–6.0 and from 1–2, where satisfactory results are obtained. At the lower pH range, operating at 35–40 amperes/ft.^{2} and 120° F. with 8 oz. of metal per gallon. A very rapid gain in the rate of deposition, better anode corrosion, complete maintenance of metal in the solution from the anode, relatively no pitting after the solution has been operated for some time and deposits of very satisfactory character are claimed. The cathode efficiency approximates 70%. As the temperature varies, the appropriate current density must be varied. WHB(7a)

High Speed Nickel Plating as Practiced in England. ERNEST R. CANNING. *Preprint* 59–9, *American Electrochemical Society*, April 1931 Meeting, 4 pages.

In England current densities of 2.2 amp./dm.^{2} and over are used. Continuous filtrations of the electrolyte, kept at 32–35° C., is necessary to eliminate suspended foreign matter and pinholes. Due to considerable loss in throwing power, the author advises against very high current densities. The preferred pH is 5.6–5.8. The cathode efficiency is 96–97%. A plate 0.001 in. (0.025 mm.) thick is obtained in 45 minutes, with a variation in thickness of not more than 45%. For adequate protection of the steel, a nickel plate of at least 0.001 in. is necessary. For sub-tropical countries composite deposits of Ni-Cu-Ni are recommended. (7a)

Electrometallurgy (7b)

Rapid Estimation of Current Efficiency in Zinc Electrolysis. *Canadian Chemistry & Metallurgy*, Vol. 15, Mar. 1931, page 77.

The staff of the Consolidated Mining & Smelting Co. of Canada, Ltd., has developed an apparatus that will reliably index the solution quality within 45 minutes. The apparatus is based on the principle that if Zn is deposited from an electrolyte free of toxic impurities, using a peroxidized Pb anode and a Zn cathode, no evolution of hydrogen occurs from the cathode and the current efficiency of Zn deposition approximates 100%. Sb, As, Co and other metals tend to lower the hydrogen overvoltage at the cathode, with liberation of some hydrogen concurrently with the deposition of Zn. The apparatus consists of a glass cell (an inverted 5-lb. reagent bottle with mouth stoppered and bottom removed) containing two lead anodes and an aluminum cathode with a diaphragm between (wood battery separators). A collecting bell attached to a gas burette is assembled over the cathode. The electrical equipment consists of a 12 volt battery or ammeter and a rheostat to control current through the cell. After electrolyzing the solution under standard plant conditions for a definite period solution is drawn up into the collecting apparatus—electrolysis continuing for a definite period. Hydrogen liberated, measured by displacement, is reduced to standard conditions of temperature, and pressure, and the current efficiency for hydrogen liberation deducted from 100 is the current efficiency for Zn deposition. WHB(7b)

Operating Data on Electrolytic Metal Production and Refining. C. L. MANTELL. *Engineering & Mining Journal*, Vol. 131, Mar. 23, 1931, pages 256–259.

Operating data from the electrolytic plants of the U. S. and Canada show the composition of electrolytes, equipment, methods of applying the current and efficiency obtained from the power, raw materials used and by-products produced. The tables cover the electrolytic refining of Cu and electrolysis of Cu-bearing solutions obtained by leaching processes, production of Zn, Cd, Pb, Ni, Sn, Ag and Au. The high power cost of processes using insoluble anodes is indicated in the tables. The diaphragm used in Ni production causes an increase in cell voltage with attendant high power costs. WHB(7b)

Process for Making Electrolytic Zinc. *South African Mining & Engineering Journal*, Vol. 41, July 19, 1930, page 591.

Brief descriptions are given of the Anaconda and Tainton processes for making electrolytic zinc. AHE(7b)

Electrolytic Copper Refining at Mount Lyell, Tasmania. WILLIAM HART. *Engineering & Mining Journal*, Vol. 131, Jan. 12, 1931, pages 3–7.

The refinery at Queenstown, Tasmania, has been in operation for 2½ years. A plan, photos and sections of the electrolytic refinery are shown and the operations outlined. The method of starting operations is interesting and probably unique, because no attempt is made to heat the electrolyte, the current being turned on when the solution is cold. The addition of 44 cells will increase the capacity to 13,000 long tons per annum. WHB(7b)

Recent Advances in Technical Electrolysis. (Neuere Fortschritte der Technischen Electrolyse.) J. BILLITER. *Chemiker-Zeitung*, Vol. 54, Mar. 12, 1930, *Fortschrittsberichte*, pages 7–13.

Contains 10 references. A review of the 1929 progress in the electrolysis of Cu, Zn, Fe, also Cd and Sn, the production of finished products, such as sheets and tubes, the electrolytic decomposition of water, the purification of water, production of alkali chlorides, the electrolytic production of Be, Na and Al, and the outlook for the future. CEM(7b)

Electrothermic Zinc. G. NEWTON KIRSEBOM. *Engineering & Mining Journal*, Vol. 131, Jan. 26, 1931, page 55.

A brief review. WHB(7b)

METALLIC COATINGS OTHER THAN ELECTROPLATING (8)

Advantages and Disadvantages of Different Types of Hot Galvanizing Furnaces. W. G. IMHOFF. *Wire & Wire Products*, Vol. 6, Feb. 1931, pages 50–52, 72–74.

The article considers the different types of galvanizing furnaces for various purposes, the fuels for heating the galvanizing pots, the destruction of kettles through corrosion attack, in particular at temperatures above 500° C., the principles of galvanizing and the control of the process. GN(8)

Northern Electric Adopts Electric Heat for Sherardizing. F. R. BARNSLEY. *Iron & Steel of Canada*, Vol. 13, Dec. 1931, pages 278–286.

Author discusses the 3 general methods of applying zinc coatings to steel and then describes the first electric sherardizing furnace to be installed in Canada. A typical operating cycle is as follows:

Charge 1600 lbs. of castings.
Zinc dust 560 lbs.
Temperature 720° F.
Radiation loss at 710° F.—9.5 kw-hrs. per hour.
Time of cycle—6½ hrs.
Thickness of deposit—0.0025 in. OWE(8)

Heat Insulation Cuts Energy Required for Electric Galvanizing. WALLACE G. IMHOFF. *Electrical World*, Vol. 97, Feb. 28, 1931, page 415.

Proper insulation around the sides, bottom and top of the kettle results in a saving in heat loss of about 36% and increase in efficiency from 14 to approximately 50%. A chart shows that more than half the radiation losses in galvanizing pots takes place at the surface of the metal. The advantages of electric galvanizing include: uniform temperature control, with attendant reduction of dross, uniform and economical zinc coating, increased pot life and better quality with less rejects. Also saving in labor and elimination of products of combustion and lowering of room temperature and favorable overhead costs. Tables and curves show the power consumption and how the saving in energy may be effected through the proper heat insulation of the kettles. WHB(8)

Some Practical Aspects of the Hot Galvanizing Industry. W. G. IMHOFF. *Iron & Steel of Canada*, Vol. 13, Nov. 1930, pages 250–259.

This article discusses the hot galvanizing process. It deals first with the quantity of zinc-coated materials produced in the United States. The various methods of galvanizing are then considered, as is also the production of sal-ammoniac skimmings, zinc ashes, and dross, the proportions of these materials obtained in various industries being considered in some detail. The microstructure of dross crystals is dealt with, and some explanation of the differences in the quantities of dross made in the various branches of the galvanizing industry is offered. OWE(8)

Some Observations on the Thickness of Hot-Dipped Zinc Coatings as Actually Measured with Micrometer Calipers. WALLACE G. IMHOFF. *American Metal Market*, Vol. 37, Nov. 22, 1930, pages 5, 10.

The thickness of the coating was measured by micrometer readings and checked by calculating the thickness from the known area and the total weight of Zn deposited. The tests were made on galvanized Fe water pails and the results are tabulated. Measured thickness on different samples averaged 0.0041–0.0045 in. and the calculated, 0.0024–0.0030, indicating an alloy bond of 0.0013–0.0017 in. WHB(8)

Galvanizing Prevents Metallic Decomposition. W. H. SPOWERS. *Wire & Wire Products*, Vol. 5, July 1930, pages 268–269, 289–290; Aug. 1930, pages 308–309, 326.

The protective action of zinc coatings is described and the use of zinc chloride as a flux in galvanizing and the formation of dross are discussed. The elimination of zinc oxide in the galvanizing kettle and the structure of zinc coatings are dealt with. GN(8)

INDUSTRIAL USES & APPLICATIONS (9)

Tube Materials for High-Pressure Water-Tube Boilers. S. F. DOREY. *Metallurgia*, Vol. 3, Nov. 1930, pages 31–34; *Engineer*, Vol. 150, Nov. 21, 1930, pages 566–568; Nov. 28, 1930, pages 588–589.

Aluminum in the Chemical Industry. H. V. CHURCHILL. *Industrial & Engineering Chemistry*, Vol. 22, Sept. 1930, pages 993–995.

The article draws attention to some uses of Al and its alloys based on corrosion resistance, and on the improvement in quality of product. Acetic acid manufacture employs Al metal; other organic acids and neutral products are manufactured or stored in Al ware. Where alkaline solutions are handled, Al metal is out of the question. The effect of high temperature is briefly discussed, as well as thermal conductivity and the importance of considering the position of Al in the electromotive series when designing Al equipment. Al paint and Al foil find considerable use as good heat reflectors and protective coatings. MEH(9)

Advantages of Lightening Transportation Means in General. What Solution Aluminum and Its Alloys Might Bring to the Problem. (Interet de l'allegement des moyensde transport en general. Quelle solution l'aluminium et ses alliages apportent a ce probleme.) A. DE BIRAN. *Revue de Metallurgie*, Vol. 27, Dec. 1930, pages 633–653.

Points out the disadvantages of disproportional relation between the carrying capacity and the weight of different transportation means. Many formulae are given to support the point and to demonstrate that the reduction of the dead weight can be advantageously achieved using light metals. JDG(9)

Roller Bearings for Locomotives and Cars. T. V. BUCKWALTER. *Railway Mechanical Engineer*, Vol. 105, Feb. 1931, pages 74–76.

A summary of questions and answers bearing upon design, operation and future possibilities of roller bearings in the railway field. GN(9)

The Manufacture of S. A. A. Cartridge Cases. F. ADCOCK. *Engineer*, Vol. 150, Dec. 19, 1930, pages 668–669; Dec. 26, 1930, pages 700–702.

Following is typical specification of cartridge case metal: Cu 69–70%, any single impurity not over 0.25%, total impurities not over 0.50% and remainder Zn. Details are given of producing accurate strip; blanking and cupping process; method of making cupping dies, including design of dies; and of final operations consisting of drawing, indenting, heading, and tapering. Article is well illustrated with diagrams. LFM(9)

The Use of Corrosion Resistant Steel in the Manufacture of Nitric Acid. (L'impiego degli acciai inossidabili nella fabbricazione dell'acido nitrico.) G. ALLEGRO. *La Metallurgia Italiana*, Vol. 23, Feb. 1931, pages 106–108.

Description and 4 photos of application of 0.10% C, 18% Cr, 6% Ni steel in nitric acid manufacture. HWG(9)

Wear Tolerances on Gages. Discussion of E. J. Bryant's Production Meeting Paper. JOHN GAILLARD. *S. A. E. Journal*, Vol. 28, Feb. 1931, pages 210–214.

Included in the paper are recommendations for establishing wear tolerances as well as manufacturing tolerances for gages and definite periods for checking gages in service. Disposal of the manufacturing tolerance was discussed, and tables of tolerances recommended by the A.E.S.C. were presented. A study of effect of gage wear and methods of inspecting gages, presented by A. W. Shoof, leads discussion. Sharp disagreement with basis of the A.E.S.C. system of tolerances is expressed by representatives of leading auto manufacturers, and a tabulation of tolerances is presented, based on standard reamer sizes adopted by both General Motors and Chrysler manufacturing units. Warning is given by W. J. Gourlie, a gage manufacturer, against dangers that gage tolerances may either increase cost of producing work, because of making manufacturing tolerances smaller than intended, or allow work outside specified tolerances. A parts manufacturer called attention to gaging problems arising from distortion of work after measuring, because of releasing casting, forging or chucking strains. Author sees need of two classes of limit, one based upon standard shafts and one upon standard holes. He emphasizes the fact that gages and tools are not an end but a means to an end. For abstract of paper also see *Metals & Alloys*, Vol. 2, Feb. 1931, page 39. MFB(9)

Results Obtained with Aluminum in Construction of Street Cars and Railway Coaches. (Resultados obtenidos con el alumino en la construction de tranvias y coches de ferrocarril.) P. M. HAENNI (Aluminum Ltd., Geneva). *Revista Minera, Metalurgica y de ingenieria*, Vol. 81, Dec. 8, 1930, pages 542, 544; Vol. 81, Dec. 24, 1930, pages 566–568; Vol. 82, Jan. 8, 1931, pages 14–16; *Zeitschrift für Metallkunde*, Vol. 23, Jan. 1931, pages 12–18.

Paper before Int. Congress of Mining and Metallurgy, Liege, June 1930. Properties and applications in railway use or cold worked and heat-treated aluminum alloys. The average weight saving in street cars is 30% if full use is made of aluminum alloys. After brief comment on the necessary precautions as to subjection of heat treatable aluminum alloys to too high a temperature it is pointed out that, for railway uses, welding should be avoided as far as possible, in favor of riveting, castings should be used as little as possible, contact with heavy metals should be avoided to prevent electrolytic attack, the dimensions of parts should be 30 to 50% greater than with steel, the metal should be painted or otherwise protected, compression members should be designed to avoid flexure, with due regard to the low modulus, and in general, fillets should be more generous than with steel. The lower modulus, tensile strength and high coefficient of expansion should be allowed for in design. The disadvantages are more than compensated by the weight saving possible. A list is given of some 30 American, 6 French, 4 German, 3 Italian, 2 English, and 1 Swiss companies which are using some light alloys, mostly of the duralumin type, in street and railway cars. Two Italian companies are listed as using some magnesium alloys. The average percentage lightening of the cars used by ten companies is 33% and the diminution in energy consumed, 28%. Maintenance costs are reduced, due to better corrosion resistance of aluminum than steel. Noise is diminished. Scrap value is large. Calculation of net cost savings is made. The experimental epoch has passed, and many roads are standardizing on aluminum. HWG + EF(9)

The Application of Copper to the Building Trade. JULIUS FRITH. *Metal Industry*, London, Vol. 38, March 6, 1931, pages 265–266.

Paper read before the Institute of Metals, Swansea Local Section, Feb. 10, 1931. Compares Cu with Pb and Fe for water pipes. The quantity of Cu dissolved by most drinking water in 24 hours seldom exceeds 0.04 part in 100,000 while safe limit is 0.14 part in 100,000. The wall thickness of Cu tubes may be reduced by using one of the various types of compression joints now available. Cu tubes are strong, stiff, light in weight, and resist freezing conditions well. It is best not to have different metals in one installation on account of corrosion difficulties. Cu roofing is advantageous because of permanence, high melting point in case of fire, and relatively low cost. Cu and its alloys are being used for doors, window frames, and shop fronts. PRK(9)

The Use of Elektron Metal in Airplane Construction. E. I. DE RIDDER. *Technical Memorandum National Advisory Committee for Aeronautics*, No. 608, Washington, Feb. 1931, mimeographed, 22 pages, 49 figures. Translated by J. Vanier from 1929 *Jahrbuch der Wissenschaftlichen Gesellschaft für Luftfahrt.*

The elektron alloys discussed are described by trade symbols, like A Z F, A Z M, A M 503, V I, etc., the chemical composition not being given. The corrodibility of magnesium alloys is admitted, but they are, nevertheless, claimed to be usable in aircraft service. Pickling in nitric-acid-chromate solution to produce a corrosion resistant surface, and varnishing are recommended. A row boat of elektron is shown which is said to be in good shape after 2 years use without revarnishing. Satisfactory use is claimed in wing ribs, fuel tanks, fittings, crank cases, carburetor manifolds, engine cowling and propeller fairing, wheels, shock absorber legs, and tail skids. Elektron sheet wing covering is classed as experimental only. One cast alloy is especially recommended for service involving high temporary stress as in landing gear and tail skids. Another is suggested for fatigue resistance and its endurance limit is said to be around 10,000 lbs./in.^{2} Chairs made from elektron were 23% lighter, 10% stronger, and the manufacturing cost was 450% compared to duralumin. It is claimed that by using elektron to the maximum the saving in empty weight is about 15%, corresponding to an increase in pay load of 40 to 70%. For example, it is calculated that a 13-passenger Junkers plane, using elektron, could carry 21 passengers. Recommendations are made for methods of welding, hot-working (at 270–330° C.), bending, riveting etc. Comparisons of merit on the basis of yield point, tensile strength, endurance limit are made with duralumin and iron. The sizes in which commercial elektron alloys are available and their various static and dynamic physical properties are stated. HWG(9)

HEAT TREATMENT (10)

Heat Treatment of Low Carbon Steel. WELTON J. CROOK. *Metal Progress*, Vol. 1, Oct. 1930, pages 47–52.

It has been found that certain steels of around 0.20% C can be materially improved in physical properties by quenching from 1600 to 1650° F. The presence of at least 0.50% Mn, and a practically complete state of deoxidation are apparently necessary conditions. (U. S. Pat. No. 1,592,181, W. J. Crook) Steels of this type are said to "regenerate" if quenching from just above the Ac_3 point results in the complete solution of the ferrite and the formation of low C martensite of 500 Brinell or over. While fully hardened low C steels have but little practical application, drawing to various temperatures after proper quenching gives a range of physical properties often superior to those of ordinary heat treated alloy steels for structural purposes. In one series of tests 2" × 1/2" flats 30" long analyzing 0.14% C and 0.58% Mn, were water quenched from 1600° F. and drawn at 1000° F. for 30 min., resulting in an increase in Y. P. from 40,200 to 65,500 without falling below a minimum of 20% elongation in 8". WHK(10)

Furnaces for Heat Treatment of High-Duty Bearing Balls. R. E. COWARD. *Wire & Wire Products*, Vol. 6, Feb. 1931, pages 53–54, 70–71.

The article describes composition, forming, hardening, quenching and tempering of ball steel with special reference to the various furnaces used. The advantages of rotary furnaces are outlined. Stationary furnaces are used for large balls. Quenching furnaces and oil baths for tempering are considered. GN(10)

Manufacture and Heat Treatment of Wrenches. J. E. HART (Walworth Company). *Fuels & Furnaces*, Vol. 8, Apr. 1930, pages 465–470, 493–494.

Bars and jaws of Stillson wrenches are drop forged from basic open-hearth steel containing 0.8% C. See *Metals & Alloys*, Vol. 1, July 1929, page 25. MS(10)

Selection and Heat Treatment of Ball Roller Bearing Steels. ERNEST F. DAVIS. *Fuels & Furnaces*, Vol. 9, Feb. 1931, pages 153–162.

Ball steels contain 1% C and 0.75–1.65% Cr, depending upon ball diameter. Smaller sizes have lower Cr content. Failures of balls in service result from surface defects, surface decarburization, excessive carbide segregation, and the commoner defects such as inclusions and center segregation. Steels for races are the high-C-Cr steel and the carburized grades such as the Ni-Mo, and the 3 1/2% Ni. Most widely used steel for carburized races is SAE 4615. Roll steels are the high-C-Cr steel, spring steel of modified SAE 4150 analysis and the carburized grades. Gives analyses of the various steels and outlines methods of heat treatment. MS(10)

Wider Use of Heat Treatment for Gray Iron Castings. H. BORNSTEIN (Deere & Co.). *Iron Age*, Vol. 126, Sept. 11, 1930, pages 688–690, 756–757.

Commercial development of heat treatment of cast Fe has been along the lines of machinability and removing internal stresses. Three classes of heat treatments used are: (1) Artificial aging; (2) Annealing; (3) Quenching. Cast Fe pistons used in automobiles are heat treated to remove internal stresses. The heating range between 900° and 1100° F. will eliminate internal stresses without causing any structural changes in the metal. Annealing temperature employed ranges from 1200–1600° F. Desirable method of heat treatment is to heat and cool slowly. Two types of furnaces used. Results of annealing regular and alloy casting:

Chemical Analysis	Regular Fe %	Alloy Fe %
Silicon	2.07	2.11
Sulphur	0.087	0.078
Phosphorus	0.16	0.17
Manganese	0.72	0.68
Total carbon	3.38	3.34
Chromium		0.25
Nickel		0.62
Transverse test 1.20 in. arbitration test bar:		
Breaking test, lbs.	2, 480	2, 730
Deflection, in.	0.29	0.28
Tensile Tests:		
Ultimate strength, lbs./in.^{2}	35,320	38,580
Brinell Hardness	217	228

VSP(10)

Heat Treatment of High-Duty Bearing Balls. R. E. COWARD. *Iron & Steel of Canada*, Vol. 14, Jan. 1931, pages 3–16.

Description of methods employed in production of high-duty bearing balls made of steel containing approximately 1% C and from 0.50 to 1.50% Cr. Methods of forming the balls, methods of heat treatment, and types of furnaces used in heat treatment are discussed. OWE(10)

Influence of Furnace Atmosphere on Correct Heat Treatment. E. W. ESSLINGER. *Metal Progress*, Vol. 1, Oct. 1930, pages 60–63.

A general discussion of the problem. WHK(10)

Advances and Trend in Heat Treating Aluminum Alloys. ROBERT J. ANDERSON. *Iron Age*, Vol. 126, Sept. 11, 1930, pages 696–698.

Metallography of Al has only been developed since 1920. Heat treated Al alloys are displacing old and previously well established materials in many engineering applications. Special compositions have been developed for particular purposes. Alloys of Al-Mg silicide type for high tension electric cables and alloy called "aldrey" used for power transmission in Europe are of recent development. Trend toward the use of electric furnaces and ovens in the Al industry is definite. Heat treated Al alloys have found the most usefulness and greatest variety of applications in the fields of modern transport—land, water and air. There is a large field for the use of heat-treated Al alloys in building of machinery and machine tools, both in case of moving parts and dead-weight components. VSP(10)

Decarburization of Steels in Molten Barium Chloride Baths. ALBERT PORTEVIN & VICTOR BERNARD. *Chimie & Industrie*, Special Number, Vol. 23, Mar. 1930, pages 243–244.

Molten $BaCl_2$ baths used to heat high-speed tool steels to 1250° C. prior to quenching cause a marked decarburization of the steel, the degree of which increases with the time of immersion, the temperature of the bath and the age of the bath. Addition of charcoal and of cyanamide did not reduce the decarburization. (10)

Hardening and Tempering, Heat Treatment Practice. (Härten und Vergüten, Die Praxis der Warmbehandlung.) E. SIMON. Julius Springer Verlag, Berlin, 1931. Paper, 6 × 9 inches, 65 pages, 116 figs. Price 2 RM.

This is a copiously illustrated, practical handbook, which is evidently popular in Germany, 18,000 copies of earlier editions having been distributed.

Many types of furnaces for hardening, tempering and carburizing are shown, and the uses of each briefly described. Few continuous furnaces are dealt with, chief consideration being given to small batch-type furnaces. Pyrometric control is very sketchily dealt with, and automatic temperature control is not considered.

Shop kinks are given for quenching with minimum distortion, and for local hardening, with sketches of the apparatus and tools used.

The pamphlet would be useful in shops doing small scale batch heat-treatment, but is far from being up-to-date as regards modern production practice in automobile plants, for example.

It is written from the practical point of view, and does not deal with metallurgical phases of heat-treatment. There is a table of contents, but no adequate index.—H. W. Gillett. (10)-B-

Hardening (10a)

Oil Hardening and Air Hardening Cast Iron. J. E. Hurst. *Iron & Steel Industry & British Foundryman*, Vol. 4, Dec. 1930, pages 91–95.

Three Ni-Cr cast irons from centrifugally cast cylinders were quenched in oil from 850° C. and in air from 875° C. They were tempered in salt at various temperatures. Tensile properties in the hardened state are very small but the strength is quickly recovered on tempering. Best properties are developed with tempering at 375–385°. The structure of tempered material is sorbitic. CHL(10a)

Deep Hardening of Structural Steels with Special Reference to the Effect of Cross-Section and Composition of the Steel (Die Durchvergütung von Konstruktionstählen unter Berücksichtigung des Einflusses von Stückquerschnitt und Legierung). H. Kallen & H. Schrader. *Archiv für Eisenhüttenwesen*, Vol. 4, Feb. 1931, pages 383–392.

A group of 14 various steels, composed of either straight C or Mn, Si, Cr, Cr-Mo and Cr-Ni steels was tested to determine the deep-hardening qualities. It is shown that the determination of the notch toughness may be suitably used for passing judgment on the hardening qualities. The yield point is still better qualified. Tensile strength, reduction of area and elongation give no clear picture. The proper ratio between yield point and tensile strength is of prime importance. Uniform deep hardening essentially depends upon the cross-section. Deep hardening is improved by alloys. The effect of various alloying elements together on the deep hardening qualities was studied. GN(10a)

Annealing (10b)

The Effect of Various Annealing Temperatures on Cold-Worked Low Carbon Steel. H. E. Publow, C. M. Heath & R. A. Gezelius. *Bulletin* No. 35, *Engineering Experiment Station, Michigan State College*, Mar. 1931, 17 pages, 22 figures.

Without appreciable change in micro-structure, low carbon steel (analysis not given) changes in hardness from 58 to 85 Rockwell B in drawing into brake drums. Olsen ductility tests for such a steel give 0.17″ deflection 9000 lbs./in.² at maximum load. Annealing at 1150–1250° F. for 1/2 hour, cooling at the rate of 7° F. per minute dropped the hardness to 60, and raised deflection to 0.36″, maximum load to over 11,000 lbs./in.² This gave better ductility than raising above the critical and cooling at that rate. Various other times and temperatures were tried. Much of the hardness produced by drawing into brake drums is acquired before the micro-structure shows apparent distortion of the grains. Annealing at 800° F. increases the hardness instead of decreasing it, prolonged heating below 1000° F. does not relieve internal strains, and the best annealing temperature is 1250–1300° F., i. e., just below the lower critical. HWG(10b)

Case Hardening & Nitrogen Hardening (10c)

Progress in Nitriding. Robert Sergeson. *Metal Progress*, Vol. 1, Oct. 1930, pages 38–41.

A brief historical review of the progress made both in the process itself and equipment used and in the development and economical production of suitable steels. Properties and applications discussed. WHK(10c)

Recent Developments in Nitriding. R. Sergeson (Republic Steel Corp.). *Iron Age*, Vol. 126, Sept. 11, 1930, pages 680–682.

Nitrided steels are heat treated to develop high physical properties. Attempts to nitride annealed structures result in a brittle part. On solid sections a growth 0.001 to 0.003 in. in diameter takes place depending on length of time of nitriding. Nitrided surfaces resist erosion, corrosion and abrasion. Recent furnace and nitriding container developments will lower cost of nitriding. Free machining of nitriding steels now possible by addition of sulphur. Tinning offers best protection for parts to be machined after nitriding. If part is merely to be kept soft the following mixture is used: 1 part sodium silicate by volume; 2 parts chrome ore (150 mesh) by volume. Composition of nitriding steel now used:

Carbon %	Manganese %	Chromium %	Aluminum %	Molybdenum %
0.10–0.20	0.40–0.70	0.80–1.30	0.60–1.20	0.15–0.25

VSP(10c)

The Development of Nitriding Plants (Die Entwicklung der Nitrieranlagen). F. Brühl. *Krupp'sche Monatshefte*, Vol. 11, Nov. 1930, pages 287–290.

The article briefly considers the nitriding process and gives an illustrated description of the latest development of German, French and American nitriding furnaces. GN(10c)

Correlation of the Crystal Structures and Hardness of Nitrided Cases. O. E. Harder & George B. Todd. *Fuels & Furnaces*, Vol. 9, Mar. 1931, pages, 295–297.

This is considerably condensed from a paper presented to the National Western Metals Congress. There is a fuller extract in *Steel*, Vol. 88, Mar. 19, 1931, pages 51–52. MS(10c)

Continuous Nitriding. R. J. Cowan. *Metal Progress*, Vol. 1, Oct. 1930, pages 93–98.

A description of a furnace and method for continuous nitriding. The furnace is of the pusher type, with a continuous gas-tight metal muffle extending throughout, charging and discharging being done through liquid seals. Burners are arranged in zones so that any temperature cycle can be maintained. The advantage of the method is that, since the ammonia is admitted at the cold end of the furnace, the metal surfaces under treatment are being continuously exposed to ammonia of a degree of dissociation suited to the temperature of the work. A series of hardness-depth curves for various degrees of dissociation are given to prove the correctness of the method. WHK(10c)

Nitriding Process of Nitrogen Case Hardening. J. E. Hurst. *Iron & Steel Industry & British Foundryman*, Vol. 3, Aug. 1930, pages 351–354; Sept. 1930, pages 379–380.

Use and factors affecting the nitriding process for various types of steels are discussed. CHL(10c)

Quenching (10d)

Heat Treatment of Carburized Parts. H. M. McQuaid. *Iron & Steel of Canada*, Vol. 14, Feb. 1931, pages 22–24.

An article reprinted from Houghton's "Black & White," in which McQuaid points out that a considerable amount of steel, which at the present time is being given the costly double treatment subsequent to carburizing, might quite successfully be quenched directly from the carburizing box. The 3 methods of single-quenching carburized work are discussed, and the types of steel suitable for use when these methods are employed are described. The article closes with a statement of the proper procedure to follow in establishing the proper heat treatment of a carburized part, assuming that the analysis selected has been chosen as the result of a careful study of the stresses and service to be met with in use. OWE(10d)

Drawing (10e)

Drawing of High-Speed Steels (Revenus des aciers rapides trempés). André Michel & Pierre Benazet. *Comptes Rendus de L'Académie des Sciences*, Vol. 192, Jan. 19, 1931, pages 163–166.

The authors describe experiments conducted with the Chévenard dilatometer on high-speed steel containing 11.09% cobalt. On the basis of these experiments the authors conclude that a single draw at a temperature less than 700° C. does not result in destruction of the austenite retained by quenching. To effect transformation a number of draws is necessary, this number becoming less as the temperature is increased. The maximum hardness obtained becomes greater as the drawing temperature is raised. The time of drawing and the speed of cooling have little influence on the effects noted. OWE(10e)

Aging (10f)

"Age Hardening" or "Improvement" of Alloys (Die "Vergütung" oder "Veredelung" von Legierungen). W. Guertler. *Zeitschrift für Metallkunde*, Vol. 22, Mar. 1930, pages 78–84.

Paper presented at the annual meeting of the *Deutsche Gesellschaft für Metallkunde*, Sept. 1929. See *Metals & Alloys*, Vol. 1, Oct. 1929, page 181. EF(10f)

The Aging of Iron and Steel. R. F. Mehl. *Iron & Steel of Canada*, Vol. 13, Dec. 1930, pages 265–287.

Report of lecture delivered at the Ontario Research Foundation, in which a very complete discussion of the types of phenomena which are grouped under the general heading, "Aging of Iron and Steel," is given. The article is illustrated by 21 diagrams and constitutes a very useful résumé of our present knowledge of this subject. OWE(10f)

The Artificial Ageing of Duralumin and Super-Duralumin. K. L. Meissner. *Engineering*, Oct. 10, 1930, Vol. 130, pages 473–475.

Condensed from paper read before the Institute of Metals, Southampton, Sept. 10, 1930. See *Metals & Alloys*, Vol. 1, Nov. 1930, page 850. LFM(10f)

The Theoretical Foundation of Duralumin-Like Age-Hardening in Ternary Systems. (Die phasentheoretischen Grundlagen der duraluminartigen Vergütung im Dreistoffsystem.) E. Scheil (Vereinigte Stahlwerke-Dortmund). *Zeitschrift für Metallkunde*, Vol. 22, Sept. 1930, pages 297–302; discussion pages 302–303. 16 illustrations.

The author deduces from theoretical considerations the various possibilities of precipitations in ternary diagrams leading to age-hardening phenomena as encountered in duralumin. Some special problems concerning the hardening of alloyed steels are dealt with in conclusion. Lecture was delivered at the Meeting of the Deutsche Gesellschaft für Metallkunde Berlin, March 1930. EF(10f)

Malleablizing (10g)

Carbon Loss and Diffusion in the Malleablizing Process. Enrique Touceda. *Metals & Alloys*, Vol. 1, Nov. 1930, page 815.

A set of 8 hard iron blocks in which the C content varied from 1.99 to 2.66% was cut to size. Each specimen originated in a different source. All were placed correspondingly in an oven packed with burnt molding and tumbling barrel sand. They were then subjected to an average annealing cycle. Micro-examinations were made before and after treatment. Successive layers were machined off for C analysis. The data indicate that there is an average loss of 0.35% of the actual C during malleabilization. It appears that the diffusion of C toward the surface practically ceases at a depth of 7/16″. ESC(10g)

JOINING OF METALS & ALLOYS (11)

Metal Joints in Aircraft Construction. T. Watson Downes. *Proceedings American Society Testing Materials*. Vol. 30, Pt. 2, 1930, pages 127–139.

Discussion appended. See *Metals & Alloys*, Vol. 1, Nov. 1930, page 850. (11)

The Joining of Aluminum and Its Alloys (La saldatura dell'alluminio e delle sue leghe). U. Magnani & C. Panseri. *La Metallurgia Italiana*, Vol. 23, Feb. 1931, pages 85–101, 26 references.

Methods for oxyacetylene welding, spot welding and hammer welding are briefly discussed. Compositions of several chloride-fluoride fluxes are given. A table of 20 compositions of solders for Al is given. These are mostly based on Sn-Zn mixtures. Zn-Cd alloys with 25 and 40% Cd and an alloy of 64 Bi, 36 Sn are also mentioned. Midway between straight welding and true soldering comes joining by means of Al alloys containing Si, Cu, Mn, Zn, etc. These are only briefly mentioned. As a curiosity is mentioned a suggestion to solder by reaction of Al with Zn salts whereby Zn is precipitated. Autogenous welding, applied with care, is applicable to pure Al where corrosion will be met, but soldered joints and adjacent metal must be protected as by varnish. Soldering is useful for repair purposes, but is seldom satisfactory from all points of view. A list of tests that may be applied to welded and soldered joints is given without details. HWG(11)

Adhesives and Adhesion. Some Mechanical Properties of Materials and Glued Metal Joints. W. B. Lee. *Industrial & Engineering Chemistry*, Vol. 22, July 1930, pages 778–780.

It has been shown that long-continued stress reduces the ultimate strength of metal joints glued with recognized adhesives, that joints between sandblasted metal surfaces made with the same shellac adhesive are weaker the greater the pressure employed in sandblasting. The relative strength of joints between smooth nickel surfaces made with various common adhesives is summarized graphically. 13 references. MEH(11)

Brazing (11a)

Electric Brazing Equipment. *Electric Railway Journal*, Vol. 75, Feb. 1931, page 103.

An equipment utilizing the resistance properties of carbon black blocks to generate heat is marketed by the General Electric Co. It consists of a transformer, fork switch and tongs for holding the carbon blocks and work. The sizes of the various parts depend on the size of the work and the joints to be made. The parts to be brazed are either designed with flat surfaces or are flattened before brazing. WHB(11a)

Resistance Brazing. *Metal Progress*, Vol. 1, Sept. 1930, pages 54–56.

The application of low voltage resistance heating to brazing and silver soldering as developed by the General Electric Co. is discussed. WHK(11a)

Soldering (11b)

Repairing Pewter. A. Eyles. *Brass World*, Vol. 27, Feb. 1931, pages 27–28.

The handling of pewter in the old days is outlined and practical notes given for the reconditioning of old pewter vessels. When repairing old pewter dents must be removed and all surfaces must be perfectly clean. A good solder contains: bismuth 50%, tin 25%, and lead 25%. Fluxes used include: rosin, Gallipoli oil, olive oil, and a mixture of rosin and olive oil. WHB(11b)

Welding & Cutting (11c)

Electric Welding of Steel. T. McLean Jasper. *Journal Western Society of Engineers*, Vol. 35, Dec. 1930, pages 415–422.

General information is given about the application of welding in manufacturing, with particular attention to large products such as welded pressure vessels. The fundamental principles of good welding are touched upon. A code, specifying the exact procedure of welding, is obsolete and fundamentally impossible. "The manufacturer who proposes to weld boilers should be willing to build a full size vessel of maximum dimensions and test it to destruction. It is hoped that the Boiler Code Committee will eventually protect the user by requiring adequate testing of the finished product." GTM+WHB(11c)

How Dissimilar and Non-Ferrous Metals Can Be Successfully Spot Welded. Part I. P. T. Gillette. *Welding*, Vol. 1, Jan. 1930, pages 163–166.

The first of a series of 7 articles by different authorities on electric resistance welding. The use of a correct combination of Elkonite-tipped electrodes, with proper observance of the factors of time, current and pressure, makes spot welding of dissimilar metals easy. The manner in which the combinations of Elkonite electrodes give a balanced heating effect is discussed. Each combination of metals and alloys must be studied as a separate problem. Tables are appended showing size of welders for dissimilar metals and also spot welds successfully made with Elkonite electrodes. ACW(11c)

Welding Processes Applicable to Aluminum. W. M. Dunlap (Aluminum Company of America). *Preprint, American Society for Testing Materials*, Mar. 1931, 4 pages.

General discussion of welding methods useful for Al and its alloys, with the advantages and drawbacks of each. Fluxes are referred to as necessary, but no details given as to satisfactory ones. HWG(11c)

Economies Result from Welded-On Overlays and Heat Treatment. Miles Catlin Smith (Stoody Co.). *Iron Age*, Vol. 126, Nov. 13, 1930, pages 1370–1371, 1437–1438.

Paper presented before the American Society for Steel Treating at Chicago. Object of investigation was to ascertain value of welded-on overlays as surface preparation for machine and other parts. VSP(11c)

Investigations on Economical Oxy-Acetylene Cutting (Untersuchungen über wirtschaftliches Brennschneiden). C. Assmann. *Autogene Metallbearbeitung*, Vol. 24, Jan. 1, 1931, pages 4–14; Jan. 15, 1931, pages 26–32.
